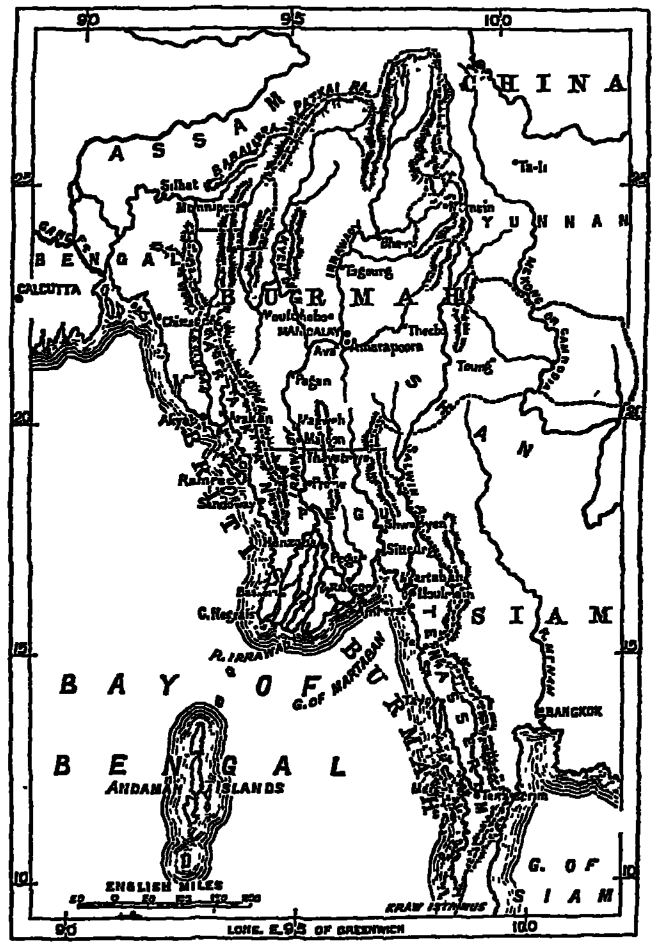
BURLINGTON, a city of the United States, the capital of the county of Des Moines in Iowa, on the right bank of the Mississippi, 207 miles by rail from Chicago. It occupies a natural amphitheatre formed by the limestone bluffs which slope backward from the river. Among the educational institutions the chief place is held by the Business College, founded in 1865, and the Baptist University, which dates from 1854. There are about eight public schools, fifteen churches, and a public library. The commercial activity of the city is very great, and is gradually increasing. Its industrial establishments comprise flour-mills, pork-packing warehouses, foundries, breweries, and soapworks; and the neighbourhood furnishes an abundant supply of coal, building stone, and lime. The city is also the centre of a considerable railway system. Laid out in 1834, it ranked for several years (1837–40) as the capital of Iowa. Population in 1860, 6706; in 1870, 14,933.

BURMAH. The Burman empire, or Independent Burmah, is situated in the S.E. of Asia, in the region beyond the mountains which form the eastern frontier of Bengal. It was formerly of very considerable extent, but its limits have been greatly contracted by British conquest. On the W. where it is conterminous with the British territories in India, the Burman empire is bounded by the province of Arakán, surrendered to the British in 1826, the petty states of Tipperah and Munnepore, and the province of Assam, from which it is separated by lofty ridges of mountains; on the S. by the British province of Pegu, acquired in 1853; on the N. by Assam and Tibet; and on the E. by China and the Shan states. Its limits extend from 19° 30′ to 28° 15′ N. lat., and from 93° 2′ to 100° 40′ E. long., comprising a territory measuring 540 miles in length from north to south, and 420 in breadth, with an area of 190,520 English square miles.

That portion of Asia in which the Burman empire is situated slopes from the central mountains towards the south; and the Burmese territory is watered by four great streams, namely, the Irawadi and the Kyen-dwen, which unite their courses at 21° 50′ N. lat., the Sittang or Pounloung, and the Salwin. The first two rivers have their sources somewhere in the northern chain of mountains in the interior, one head stream of the Irawadi probably coming from Tibet; the Salwin further to the east in Tibet; and the Sittang, which is the smallest of the four, in the hills to the S.E. of Mandalay: they all run in a southerly course to the Indian Ocean. The Irawadi and the Salwin are large rivers, which in the lower part of their course overflow the flat country on their banks during the season of the rains, and in the upper force their way through magnificent defiles. The former is navigable a considerable distance above Bhamo; but the latter is practically useless as a means of communication, owing to the frequent obstacles in its channel. The Burmese empire with its present limits contains no maritime districts, and only isolated tracts of alluvial plain; it is in the main an upland territory, bounded at its southern extremity by a frontier line at the distance of about 200 miles from the mouths of the Irawadi, in 19° 30′ N. lat. From this point the country begins to rise, and thence for about 300 miles farther it contains much rolling country intersected by occasional hill ranges; beyond this it is wild and mountainous.

Productions.

Though inferior in point of fertility to the low-lying tracts of British Burmah, the upland country is far from being unproductive. The chief crops are rice (of which the Burmese count 102 different sorts), maize, millet, wheat, various pulses, tobacco, cotton, and indigo. The sugar cane appears to have been long known to the Burmese;



Sketch-Map of Burmah.

but, though the climate and soil are extremely favourable, it is not generally cultivated. A cheap and coarse sugar is obtained from the juice of the Palmyra palm, which abounds in the tract south of the capital. The cocoa and areca palms are not common. The tea-plant, which is indigenous, is cultivated in the hills by some of the mountain tribes at the distance of about five days' journey, and by others in still greater perfection at the distance of about ten days' journey, from the capital. It seems, however, to be another plant, probably the *Elæodendron persicum*, which furnishes the principal ingredient in the hlapét, or pickled tea, that forms one of the favourite condiments of Burmah. Cotton is grown in every part of the kingdom and its dependencies, but chiefly in the dry lands and climate of the upper provinces. Indigo is indigenous, and is universally cultivated, but in a very rude manner; it is still

more rudely manufactured, and is wholly unfit for exportation.

The most common fruits in Burmah are the mango, the orange, the citron, the pine, the custard apple, the jack, the papaya, and the plantain. The yam and the sweet potato are grown, but not extensively; the common potato is unknown. Onions are produced; and capsicum, which, after salt, is the most ordinary condiment used by the Burmese, is cultivated everywhere.

rests. The forests of Burmah abound in fine trees. Among these the teak holds a conspicuous place; some of the finest teak forests were lost to the Burmese, however, with Pegu. Almost every description of timber known in India is produced in the Burmese forests, from which also an abundant supply is obtained of the varnish employed by the Shans and the Burmese in their manufacture of lacquered ware. Sticklac of an excellent quality is obtained in the woods.[1]

inerals. Burmah is rich in minerals, and produces gold, silver, copper, tin, lead, antimony, bismuth, amber, coal, petroleum, nitre, natron, salt, limestone, and marble, the jade or yu of the Chinese, sapphires, and other precious stones. Gold is found in the sands of different rivers, and also towards the Shan territory on the eastern frontier; but the demand is very much greater than the native supply. Silver is got also near the Chinese frontier. The mountainous districts of the Shan territory contain almost all the other metals; but they are not worked, and the copper and tin, which are seen in the capital, are imported from China. Iron is found in several places, and is wrought especially at Poukpa, near a mountain of that name to the eastward of the old capital Pagán, and also at Maedoo, north-west of the capital; but, owing to ignorance and the want of proper methods, about 30 or 40 per cent. of the metal is lost in the process. Large deposits of rich magnetic oxide, as yet untouched, exist in the ridges east of the capital near the banks of the navigable river Myit-Ngé, and the same district contains lime in great abundance and of remarkable whiteness; while statuary marble, equal to the best Italian specimens, is found about 15 miles north of the capital and east of the Irawadi. Mines of amber are wrought, among other places, at Hookhong or Payendwen, near the sources of the Kyen-dwen, and their produce must be abundant if one may judge from the price of the article at the capital. Nitre, natron, and salt are found in various quarters. Sulphur also occurs in some places, as in the district of Silleh-Myo and in the neighbourhood of the petroleum wells; but the quantity is comparatively small, and a supply has to be obtained from China. Coal has been discovered in patches, but not in any quantity worth working. Petroleum, which is used by all ranks among the Burmese for burning in lamps, and also for smearing wood as a preservative against insects, is found near the village of Ye-nang-gyoung, on the banks of the Irawadi. Here are upwards of one hundred pits or wells, with a general depth of from 210 to 240 feet; though some of them are deeper, and reach to the depth of 300 feet. The shaft is of a square form, from 3 to 4 feet across, and lined with horizontal balks. The liquid appears to boil up from the bottom like an abundant spring, and is extracted in buckets, and sent to all quarters of the country. The annual yield is calculated at 11,690 tons. A good deal is now imported into England.[2]

The precious stones which are produced in the Burmese territories are chiefly the sapphire and the ruby. They are found about 60 or 70 miles in a north-east direction from the capital, over an area of about 100 square miles, by sinking pits in the gem beds. The varieties of the sapphire found there are the *blue* or oriental sapphire, the *red* or oriental ruby, the *purple* or oriental amethyst, the *yellow* or oriental topaz, besides different varieties of chrysoberyl and spinelle. The Crown lays claim to the produce of these rivers; and all the stones that exceed the value of £10 are sent to the treasury.[3] No stranger is ever permitted to approach the spots where these precious stones are found. The yu or jade mines are situated in the Mogoung district, about 25 miles south-west of Meinkhoom. During certain seasons no fewer than 1000 men—Shans, Chinese, Panthays, and Kakhyens—are engaged in the excavation of the stone, which is found in the form of rounded boulders, sometimes of considerable size. Each digger pays so much a month for the right of search, and all he finds becomes his own.[4] Momien, in Yunnan, was formerly the chief seat of the manufacture of the jade, and still produces a considerable quantity of small articles.

The country of the Burmese, abounding in forests, affords extensive shelter to wild animals. The elephant and the rhinoceros—both the one-horned (*R. indicus*) and the two-horned (*R. sumatranus*)—are found in the deep forests of the country. The tiger and the leopard are numerous, as well as the wild hog, and several species of deer, such as the Indian roe, the axis, and the barking deer (*Cervus muntjac*). In the Irawadi is found, as far up as Bhamo, a peculiar kind of dolphin. The rivers and lakes abound with fish, from which the inhabitants prepare their favourite condiment of ngapee. A detailed description of several of the species will be found in Day's contributions to the *Proceedings of the Zoological Society*, 1869, 1870. Of birds, the jungle-fowl is common, and is seen in coveys in all the forests of the country; while domestic breeds, often of very large size, are kept in great numbers, not only for the sake of the eggs or the flesh, but also to afford amusement of a barbarous kind. Aquatic birds of various kinds are very numerous, such as geese, darters (*Flotus melanogaster*), scissor-bills (*Rhyncops nigra*), adjutants (*Leptoptilos argala*), pelicans, cormorants, cranes (*Grus antigone*, in Burmese *gyoja*), whimbrels, plovers, and ibises. There are also peacocks, and varieties of pheasants, partridges, and quails.[5] Anim

The domestic animals are the ox, the buffalo, and the horse. Oxen are used for draught in the upper country, and buffaloes in the southern parts. They are of a good description, and, ranging in the luxuriant pastures of the plains, they commonly appear in high order. The buffalo is confined to agricultural labour, and the ox alone is used as a beast of burden or of draught. The Burman horses, which are rarely more than thirteen hands high, are never used but for riding. Elephants are kept for the pleasure of the king, and the taming of those that are newly caught is one of the favourite spectacles of the people. A white elephant (apparently an albino), when found, is greatly prized, and is kept at court as a sacred appendage of royalty. The dog is neglected, and is seen prowling about the streets, a prey to famine and disease. Cats are numerous; and about the capital a few goats and sheep, of a puny race, are kept more for curiosity than for use. A few asses are also seen, which are brought from China. The camel is not known.

The Burmese in person have the Mongoloid characteristics, common to the Indo-Chinese races, the Tibetans, and tribes of the Eastern Himalaya. They may be gene- Inhabitants.

[1] An article on the Burman flora, by S. Kurtz, will be found in the *Journal of the Asiatic Society of Bengal* for 1874.

[2] See Appendix to Yule's *Narrative*.

[3] *Journal As. Soc. of Bengal*, 1833.

[4] The specimens that are most highly prized are of an emerald green; but red and pale pink are also favourite colours.

[5] An important addition to the natural history of the country has just been made by the representatives of the late Mr E. Blyth in the shape of a "Catalogue of the Mammals and Birds of Burmah," published as an extra number of the *Journal of the As. Soc. of Bengal*, 1875.

rally described as of a stout, active, well-proportioned form; of a brown but never of an intensely dark complexion, with black, coarse, lank, and abundant hair, and a little more beard than is possessed by the Siamese. The name they give their own race is Mran-má (as written), generally pronounced Ba-má, and from this the various forms of "Burmah" appear to have been taken. Besides the Burmese proper, there are numerous tribes of Paloungs, Toungthoos, Karens, and others toward the east, many of them in a state of semi-independence; and all round the northern frontier and along the ranges that traverse the upper regions, vast hordes of Kakhyens or Singphos maintain a rough, cateran life, and come down to levy black mail on the more peaceful inhabitants. The Shans constitute a great number of small principalities along the whole eastern border, subject some to Burmah, some to China, some to Siam, and in some cases owning a double allegiance, according to their position. The Shans everywhere profess Buddhism, and have some kind of literature and the traces of culture. To their race the Siamese themselves belong. The Kakhyens are square-faced, strong-jawed, and oblique-eyed. They are still in a low state of civilization, are destitute of letters, and continue in paganism. Their chiefs are supported by offerings in kind,—receiving, for example, a leg of every animal that is killed. One kind of industry—the manufacture of toddy and arrack—is extensively carried on, and the whole population are regular consumers of the produce.[1] Various other tribes, as the Pwons and the Kakoos, are scattered throughout the empire; but they are not of much individual importance. The population of the country has been variously estimated and grossly exaggerated by the ignorance of Europeans, who have raised it to 17,000,000, 19,000,000, and even 33,000,000. Mr Craufurd, on the best data that he could procure, rated the inhabitants at 22 to the square mile, which, under the now contracted limits of the empire, would give a total population of 3,090,000, and Colonel Yule estimated, in 1855, that, within the area between the British frontier and 24° N. lat., it probably did not exceed 1,200,000; while within the whole empire at its widest limits there were not more than 3,000,000. Count Bethlen states, in 1874, that he obtained statistics of the houses in Burmah from a Burmese official, which made the number 700,000, without including those among the Shans to the east of the Salwin; so that if we allow five inhabitants to each we have 3,500,000 for a total population, and if we include the Shans probably 4,000,000.

vern-nt.

The Burmese government is a pure despotism, the king dispensing torture, imprisonment, or death, according to his sovereign discretion. The chief object of government seems to be the personal honour and aggrandizement of the monarch; and the only restraint on the exercise of his prerogative is the fear of an insurrection He is assisted in his administration by a public and a privy council, known respectively as the Hlot-dau and the Byadeit; all questions, before they are submitted to the public advisers of his majesty, are debated in the privy council, which consists generally of four Atwen-woons to whom are attached deputies, secretaries and other officers (Tsaré dau-gyis, "great royal writers;" Than-dau-zens, "receivers of the royal voice"), who carry messages, and report from time to time the proceedings of the council to the king. The Hlot-dau also usually consists of four ministers or Woongyis, and is presided over by the crown-prince (Einshé-men, or lord of the eastern house). The paymaster-general is an officer of high importance; and the other officers of distinction are the king's armour-bearer and the master of the elephants, but the latter have no share in the administration of public affairs. The king may order any of those great officers to be punished at his pleasure; and a minister may, by his order, be seized by the public executioner, and laid at the side of the road for hours under the burning sun with a weight upon his breast; and after undergoing this disgraceful punishment, may continue to discharge his high function as before. The country at large is ruled by provincial governors, and is divided into provinces (or Myos), townships, districts, and villages. The civil, military, judicial, and fiscal administration of the province is vested in the governor, or Myo-woon, who exercises the power of life and death, though in all civil cases an appeal lies from his sentence to the chief council at the capital. In all the townships and villages there are judges with a subordinate jurisdiction. But from a mere detail of the provincial administration and judicial institutions of the Burmese, their extreme inefficiency can scarcely be known. No Burmese officer ever receives a fixed salary. The higher class is paid by an assignment either of land or of the labour and industry of a given portion of the inhabitants, and the inferior magistrates by fees, perquisites, and other emoluments; and hence extortion and bribery prevail amongst all the functionaries of the Burmese Government. Justice is openly exposed for sale; and the exercise of the judicial functions is so lucrative, that the two executive councils have by their encroachments deprived the regular judge of the greater part of his employment.

The Burmese laws are mainly contained in the *Dhammasat*, a code ascribed to Manu, but quite different from the Manu's Code of the Brahmans. It is said to have been introduced into Burmah from Ceylon by Buddaghosha, the traditional apostle of the Indo-Chinese nations.[2] The criminal code is barbarous and severe, and the punishments are shocking to humanity. Gang robbery, desertion from the king's service, robbing of temples, and sedition or treason, are considered the most heinous crimes, and are cruelly punished, the criminal being in some cases embowelled, or thrown to wild beasts. Decapitation is the general mode of execution, but crucifixion and fracture of the limbs are also practised, and women are usually put to death by the stroke of a bludgeon across the throat. For minor offences, fines, whipping, and imprisonments are the punishments adjudged. In important cases torture is applied both to principals and witnesses; and the jailers often torture their prisoners in order to extort money from them. The English and American prisoners during the war of 1824 were frequently tortured, and had to pay fines to the jailer in order to procure milder treatment. Trial by ordeal is sometimes resorted to, as well as other superstitious modes of procedure. The administration of justice, however vexatious and expensive, is far from efficient; and the police is as bad as can possibly be conceived.

Ranks of society

There are no hereditary honours under the Burmese Government. All the public functionaries may be dismissed from their offices, and deprived of their rank at the caprice of the sovereign; while any subject, with the exception of a slave or outcast, may aspire to the first offices in the state, to which, in reality, persons of very mean origin do frequently attain. The great officers of Government hold the first rank after the king and the princes of the blood, and are distinguished by a chain or badge, which is the order of nobility, and of which there are different degrees, distinguished by the number of strings or small chains which compose the ornament. Three of open chain-work mark the lowest rank; three of neatly-twisted wire the next; there are then six, nine, twelve, and finally twenty-four, which the king alone is entitled to wear. But every article possessed

[1] See for details regarding the Shans and Kakhyens Anderson's *Expedition to Eastern Yunan*, ch v. Appendix B contains a list of 200 words in the Shan, Kakhyen, Paloung, and Leesaw languages.

[2] A translation has been made into English by Richardson.

by a Burman for use or ornament—his ear-rings, cap of ceremony, horse-furniture, the material of his drinking-cup, if it be of gold or any other metal, the colour and quality of his umbrella (an article in general use, and one of the principal insignia of rank), whether it be of brown varnished paper, red, green, gilded, or plain white, the royal colour—all indicate the rank of the person; if any of the lower orders usurp the insignia of a higher class, he may be slain with impunity by the first person who meets him; and so exclusive is the aristocratical spirit of the higher orders, that such a usurpation would be sure of punishment.

When a merchant acquires property he is registered by a royal edict under the name of Thuthé or "rich man," which gives him a title to the protection of the court, while it exposes him also to regular extortion. The priesthood form a separate order, who are interdicted from all other employment, and are supported by voluntary contributions. They are distinguished by the yellow colours in their dress, which it would be reckoned sacrilege in any other person to wear. A formal complaint was made, during the conferences with the British previous to the peace, because some of their camp followers were seen dressed in yellow clothes. There is also an order of nuns and priestesses, who make a vow of chastity, but may at any time quit their order.

The free labouring population consist of proprietors or common labourers; and they are all considered the slaves of the king, who may at all times call for their services as soldiers, artizans, or common labourers. Hence a Burman, being the property of the king, can never quit the country without his especial permission, which is only granted for a limited time, and never to women on any pretence. The British and others who had children by Burmese women during a residence in the country experienced the greatest difficulty, even with the aid of heavy douceurs, in taking them along with them. The *Dhammasat* numbers seven classes of slaves, of which the most important are prisoners of war, and those who have mortgaged their services for a debt. The class of outcasts consists of the slaves of the pagodas, the burners of the dead, the jailers and executioners (who are generally condemned criminals), and the lepers and other incurables, who are held in great abhorrence, and treated with singular caprice and cruelty. They are condemned to dwell alone, and in a state of disgrace; and any man who is infected with leprosy, however high his rank, is forced, by continual bribes to the officers of justice, to purchase an exemption from the penalties which attach to him. Prostitutes are also considered as outcasts. The women in Burmah are not shut up as in many other parts of the East, and excluded from the sight of men; on the contrary, they are suffered to appear openly in society, and have free access in their own name to the courts of law, where, if ill-treatment is proved, divorce is readily obtained. In many other respects, however, they are exposed to the most degrading treatment. They are sold for a time to strangers; and the practice is not considered shameful, nor the female in any respect dishonoured. They are seldom unfaithful to their new master; and many of them have proved essentially useful to strangers in the Burmese dominions, being generally of industrious and domestic habits, and not addicted to vice.

Revenue.

The taxes from which the public revenue arises are in general rude and ill-contrived expedients for extortion, and are vexatious to the people at the same time that they are little productive to the state. The most important is the house or family tax, which is said to be assessed by a *Doomsday Book*, compiled by order of Mentaragyi in 1783. The amount varies greatly in different years, and to a remarkable extent in different districts. Next in order is the tax on agriculture, which is also very irregularly imposed. A large part of the cultivated land of the kingdom is assigned to favourites of the court or to public functionaries in lieu of stipends or salaries, or is appropriated to the expenses of public establishments, such as war-boats, elephants, &c.; and this assignment conveys a right to tax the inhabitants according to the discretion of the assignee. The court favourites who receive these grants generally appoint agents to manage their estates; they pay a certain tax or quit-rent to the crown, and their agents extort from the cultivators as much more as they can by every mode of oppression, often by torture. Besides this stated tax, extraordinary contributions are levied by the council of the state directly from the lords and nobles to whom the lands are assigned, who in their turn levy it from the cultivators, and generally make it a pretence for plunder and extortion. Taxes are also laid on fruit-trees, on the sugar palm, on the tobacco-land on the teak forests, on the petroleum springs, on mines of gold and precious stones, on the fishery of ponds, lakes, rivers, and salt-water creeks, on the manufacture of salt, on the eggs of the green turtle, and on esculent swallows' nests. As the consumption of wines, spirits, opium, and other intoxicating drugs is forbidden by law, they cannot, of course, be subject to any tax.

In many of the useful arts the Burmese have not made any great advances, while in others they are possessed of no small amount of proficiency. The architecture of religious edifices erected in the Middle Ages is of striking and effective character, though only of brick. The general style bears evidence of an Indian origin; but numerous local modifications have been introduced. Perhaps the feature of most interest is the use of the pointed arch as well as the flat and the circular, and that at a time long anterior to its employment in India. Modern buildings are chiefly of wood; palaces and monasteries, carved with extraordinary richness of detail, and often gilt all over, present an aspect of barbaric splendour. The dagobas, or solid domes, which form at once the objects and the localities of Buddhist worship, are almost the only brick structures now erected; and these are often gilt all over. In carving the Burmese artisans display unusual skill and inventiveness, and give full scope to the working of a luxuriant and whimsical fancy. As in our mediæval woodwork, sometimes there is often displayed a large amount of satirical and facetious caricature. The application of gilding is carried to an extravagant extent; as much as £40,000 is said to have been expended on this article for a single temple. The finest architectural monuments are to be found in the deserted city of Pagán; and many of the most magnificent are greatly shattered by earthquakes.[1] The number of religious buildings, small and great, throughout the country is enormous; at every turn the traveller finds pagodas or kyoungs (monasteries), or lesser shrines, or zayats (resting-places for travellers founded by the Buddhists in order to acquire religious merit). The ordinary buildings are of a very slight construction, and the architect is prevented from giving them any great height by the whimsical prejudice of the people against any one walking over their heads. The whole process of the cotton manufacture is performed by women, who use a rude but efficient species of loom, and produce an excellent cloth, though they are much inferior in dexterity to the Indian artisans. Silk cloths are manufactured at different places from Chinese silk. The favourite patterns are zigzag longitudinal stripes of different colours, and the brilliance of the contrasts is frequently gorgeous in its results. The dyeing of the yellow robes of the priests is effected by means of the leaves of the jacktree

Arts and manufactures.

[1] For full details the reader ought to consult Captain Yule's chapter on Pagán.

The common, coarse, unglazed earthenware is of an excellent quality; and a better description of pottery is also made. The art of making porcelain, however, is entirely unknown, and this ware is imported from China. Iron ore, as already mentioned, is smelted; but the Burmans cannot manufacture steel, which is brought from Bengal. Bell-founding has been carried to considerable perfection; and the craftsmen take pride in the magnitude of some of their productions. Perhaps the largest specimen is that in the neighbourhood of Amarapura, which measures 16 feet across the lip and weighs about 80 tons. Coarse articles of cutlery, including swords, spears, knives, also muskets and matchlocks, scissors, and carpenters' tools, are manufactured in the capital, and gold and silver ornaments are produced in every considerable place in the country. Embossed work in drinking cups and the like is executed with great richness of effect. North of the capital, and east of the Irawadi, as before stated, is an entire hill of pure white marble, and there are sculptured marble images of Gautama or Buddha. The marble is of the finest quality; and the workmen give it an exquisite polish by means of a paste of pulverized fossil wood. The chief seat of the manufacture of lacquered wares is at Nyoun-goo, near the ancient city of Pagán. Since Burmah was deprived of its harbours and maritime districts, its foreign commerce has been extremely limited. The trade of the country centres chiefly in the capital. The imports are rice, pickled and dried fish, and foreign commodities obtained from Bengal, the Asiatic Archipelago, and Europe. Petroleum, saltpetre, lime, paper, lacquer-ware, cotton and silk fabrics, iron, cutlery, some brass ware, terra japonica, sugar, and tamarinds are given in exchange. One of the most important branches of the trade of the country was formerly that maintained with the Chinese province of Yunnan; but it has been for a considerable period in abeyance owing to the disturbed state of the frontier counties. The principal marts of this trade, which was carried on at annual fairs, were Madé, near the capital, and Bhamo. The Chinese caravan, setting out from the western province of Yunnan at the close of the periodical rains, generally reached Burmah in the beginning of December, after a journey of six weeks over difficult and mountainous roads. The principal fair was held at Bhamo, comparatively few traders arriving at the capital. The articles imported from China were raw silk, wrought copper, orpiment or yellow arsenic from the mines in Yunnan (of a very fine quality, which found its way into Western Asia, and into Europe through Calcutta), quicksilver, vermilion, iron pans, brass-wire, tin, lead, alum, silver, gold and gold-leaf, earthenware, paints, carpets, rhubarb, tea, honey, velvets and other wrought silks, spirits, musk, verdigris, dry fruits, paper, fans, umbrellas, shoes, and wearing apparel. The metals were chiefly produced in the province of Yunnan. The articles sent to China consisted of raw cotton, by far the most considerable article of export; feathers, chiefly of the blue jay, for ornamenting the dresses of ceremony of the Chinese mandarins; esculent swallows' nests, ivory, rhinoceros' and deers' horns; sapphires, used for buttons to the caps of the Chinese officers of rank, jade, and amber, with a small quantity of British woollens. The trade of the northern part of Burmah proper is chiefly carried on at large fairs held in connection with religious festivals. One of the most important articles, in addition to European cloth goods, is salt, for their supply of which all the hill-tribes are dependent on Burmah.[1]

Money. The currency used by the Burmese is of the rudest description. For the smaller payments lead is employed; and for the larger payments silver almost exclusively. This is not coined into pieces of any known weight and fineness; and in every payment of any consequence the metal must be weighed and is generally assayed, for which a premium is paid to the bankers or money-changers of $2\frac{1}{2}$ per cent. besides 1 per cent. which they say is lost in the operation. There are three or four different alloys of silver in common use as money; the best is Bau, which is almost pure; next is Dain, with about 6·4 per cent. of copper; and so on through several grades. An attempt was made by King Mentaragyi to introduce a coinage; but his plans failed because he fixed the current value of his money considerably above the real value of the silver. The high rate of interest for money—which is 25 per cent., and 60 per cent. when no security is given—is another proof of the low state of commerce among the Burmese. The seeds of the *Abrus precatorius* (Khyin Rhwe), a little red and black pea, serve as the smallest weight; they ordinarily weigh about a grain, but vary from one to two. Two of them make a rhwe-kyi, four rhwe-kyis a great pae, four great paes a mat, four mats a kyap, and 100 kyaps a piktha (peissa) or viss, which is equal to 3·6516 lb avoirdupois. The Burmese year is divided into three seasons and twelve months, beginning with what corresponds to our April, and every third year a month is intercalated. Every pakka or half-month consists of 15 days (ret) of 60 narih each. The ret is divided into the nay or period from sunrise to sunset, and the gnyin or period from sunset to sunrise,—the 60 narih being assigned in different proportions to the two periods in each of the twelve months, the first month having 30 in each period, and the second 30 in the daytime and 28 in the night, and so on. The Burmese have borrowed their astronomy and astrology, as well as this division of the day, from the Hindus. They are ignorant of oceanic navigation; and in their voyages to Calcutta, during the fine season, they creep along the coast, never losing sight of it.

The Burmese proper use a monosyllabic language, spoken with distinctive tones, like the Chinese and several other Indo-Chinese tongues. Its vocabulary shows distinct relation to Chinese on one side and to Tibetan on another. In contrast with Siamese it is a very soft and flexible language, and its monosyllabic character is somewhat modified in pronunciation. It has no distinctly sibilant sound, the only letter approximate to "s" having a resemblance rather to the English "th." It is a literary language, and has been under cultivation for perhaps six or seven centuries. It is written with an alphabet of Indian origin, which probably came in with Buddhism; and most of the letters are of a more or less circular form. The Pali remaining the dialect of sacred literature, the Burmese has been almost confined to secular uses. It has developed a poetic diction of such complete individuality that it is unintelligible without special study. Another peculiar dialect, largely mingled with Pali elements, is spoken at court, and also requires separate study, as it substitutes a vocabulary of elaborate artificiality subordinate to the etiquette of the courtiers. The word for "to go," for example, is different according as it is said that the king goes, or the prince goes, or the priest goes. Of the literary forms in which the Burmese express themselves, the favourite one is the drama, which appears under the various forms of masquerades, puppet shows, ballet-opera, and farces, as well as in the more dignified character of the regular tragedy. The moral character of the plays is often of the lowest kind, the utmost licence both of speech and action being allowed on the stage. The scenery is of a very simple and purely suggestive kind, a single branch of a tree standing for a forest, and frequently the filling up of the dialogue is largely left to the ingenuity of the actors, little more than hints of the plot being con-

[1] An interesting survey of the various trade-routes from Burmah to China is given by Mr J. Coryton in the *Jour. of the R. Geogr. Soc.* for 1875.

tained in many of the librettos. The popular interest in the dramatic exhibitions is intense, and, as in Siam, the same piece often drags its slow length along for days together. Specimens of the plots will be found in the appendixes to Yule's *Narrative*, Williams's *Through Burmah*, and Bastian's *Reisen*. The national chronicles, or chronicles of the kings (*Maha-Radza Weng*), go back at least in name to the early centuries of the Christian era, but their historical value is of a very dubious kind. Libraries are common throughout the country, principally in the monasteries. Though a certain kind of paper is manufactured from bamboo pulp, the usual material of the books is the palm leaf, while for ordinary notebook purposes a kind of black tablet, called a *parabeik*, and a steatite pencil are employed. A dictionary of Burmese was published by Judson at Maulmein in 1852; Schleiermacher made the language the object of a remarkable study in his *Influence of Writing upon Language*, 1835; and Bastian has contributed an essay on the literature to the *Zeitschrift der Deutschen Morgenl. Gesellschaft*, 1863, and has also published an interesting sketch of the peculiarities of the language in his *Sprachvergleichende Studien*, Leipsic, 1870.

igion. The Burmese are votaries of Buddha, and the rites, doctrines, and priesthood are in their main features the same as in other countries where Buddhism prevails. Every Burman must, at some period or other of his life, spend some time in a monastery; and it is no uncommon thing for a man to retire for a longer or shorter period from the bustle of life without any intention of permanently adopting the yellow robe which is the distinctive mark of the regular monk. Dr Bastian has supplied a great many interesting details on the religious beliefs and ceremonies of the people, but they are as yet unfortunately scattered through the pages of his *Travels*. Neither Christianity nor Mahometanism has made much progress, though a certain number of Mahometans have existed, especially at the capital, for a long time, and have mosques there. Foreigners enjoy religious toleration, but the Burmese rulers view any attempt to convert the natives to the Christian or any other foreign faith as an interference with their allegiance. An American mission was settled in the country in 1815, under the conduct of Dr Judson before mentioned, who brought to this perilous service zeal and discretion; but it entirely failed of success, not from any bigotry on the part of the natives, but from the opposition of men in power. On the war breaking out with the British the missionaries were imprisoned, and narrowly escaped with their lives, and on their release they retired to prosecute their labours in the British province of Martaban. There are now in the capital representatives of both English and French missionary agencies.

Education throughout the Burman empire is still in the ecclesiastical stage, but the educational statistics compare favourably with those of many portions of Europe. The first book, according to Dr Bastian, which is put into the hands of the boys in the monastery schools is the *Sin-pungyi*, or Great Basket of Learning, in which the meaning of the Burmese letters is explained. After this they learn the injunctious of religion in the *Mengalasut*, and next the prayers of Gautama in the *Pharitgyi*, which is written in Pali, so that their study consists in mechanically committing it to memory. They then proceed to the *Djats* (stories or legends) in which the Burmese words are mingled with Pali expressions and contractions; later on they pass to the study of *Saddo* or grammar, and finally to that of the *Yok* or general cyclopædia. For those who enter the monastic profession there remain the Pali texts. The historical books are then read, as well as the *Pu-és* or dramatic productions. Fluency of speech and great skill in carrying on an argument according to their own system of dialectics are the common possessions of the educated Burmese, and an unshaken conviction in the truth of their religion is almost universal.

It is probable that Burmah is the *Chryse Regio* of Ptolemy, a name parallel in meaning to *Sonaparanta*, the classic Pali title assigned to the country round the capital in Burmese documents. The royal history traces the lineage of the kings to the ancient Buddhist monarchs of India. This no doubt is fabulous, but it is hard to say how early communication with Gangetic India began. From the 11th to the 13th century the old Burman empire was at the height of its power, and to this period belong the splendid remains of architecture at Pagán. The city and the dynasty were destroyed by a Chinese (or rather Mongol) invasion (1284 A.D.) in the reign of Kublai Khan. After that the empire fell to a low ebb, and Central Burmah was often subject to Shan dynasties. In the early part of the 16th century the Burmese princes of Toungoo, in the north-east of Pegu, began to rise to power, and established a dynasty which at one time held possession of Pegu, Ava, and Arakán. They made their capital at Pegu, History.
and to this dynasty belong the gorgeous descriptions of some of the travellers of the 16th century. Their wars exhausted the country, and before the end of the century it was in the greatest decay. A new dynasty arose in Ava, which subdued Pegu, and maintained their supremacy throughout the 17th and during the first forty years of the 18th century. The Peguans or Taleins then revolted, and having taken the capital Ava, and made the king prisoner, reduced the whole country to submission. Alompra, left by the conqueror in charge of the village of Monchaboo, planned the deliverance of his country. He attacked the Peguans at first with small detachments; but when his forces increased, he suddenly advanced, and took possession of the capital in the autumn of 1753. In 1754 the Peguans sent an armament of war-boats against Ava, but they were totally defeated by Alompra; while in the districts of Prome, Donabew, Loonzay, &c., the Burmans revolted, and expelled all the Pegu garrisons in their towns. In 1754 Prome was besieged by the king of Pegu, who was again defeated by Alompra, and the war was transferred from the upper provinces to the mouths of the navigable rivers, and the numerous creeks and canals which intersect the lower country. In 1755 Apporaza, the king of Pegu's brother, was equally unsuccessful, after which the Peguans were driven from Bassein and the adjacent country, and were forced to withdraw to the fortress of Syriam, distant twelve miles from Rangoon. Here they enjoyed a brief repose, Alompra being called away to quell an insurrection of his own subjects, and to repel an invasion of the Siamese; but returning victorious, he laid siege to the fortress of Syriam and took it by surprise. In these wars the French sided with the Peguans, the English with the Burmans. Dupleix, the governor of Pondicherry, had sent two ships to the aid of the former; but the master of the first, was decoyed up the river by Alompra, where he was massacred along with his whole crew. The other escaped to Pondicherry. Alompra was now master of all the navigable rivers; and the Peguans, shut out from foreign aid, were finally subdued. In 1757 the conqueror laid siege to the city of Pegu, which capitulated, on condition that their own king should govern the country, but that he should do homage for his kingdom, and should also surrender his daughter to the victorious monarch. Alompra never contemplated the fulfilment of the condition; and having obtained posesssion of the town, abandoned it to the fury of his soldiers. In the following year the Peguans vainly endeavoured to throw off the yoke. Alompra afterwards reduced the town and district of Tavoy, and finally undertook the conquest of

the Siamese. His army advanced to Mergui and Tenasserim, both which towns were taken; and he was besieging the capital of Siam when he was taken ill. He immediately ordered his army to retreat, in hopes of reaching his capital alive; but he expired on the way, in 1760, in the fiftieth year of his age, after he had reigned eight years. In the previous year he had massacred the English of the establishment of Negrais, whom he suspected of assisting the Peguans. He was succeeded by his oldest son Noungdaugyi, whose reign was disturbed by the rebellion of his brother Tshen-byo-yen or Shembuan, and afterwards by one of his father's generals. He died in little more than three years, leaving one son in his infancy; and on his decease the throne was seized by his brother Tshen-byo-yen. The new king was intent, like his predecessors, on the conquest of the adjacent states, and accordingly made war in 1765 on the Munnipore kingdom, and also on the Siamese, with partial success. In the following year he defeated the Siamese, and, after a long blockade, obtained possession of their capital. But while the Burmans were extending their conquests in this quarter, they were invaded by a Chinese army of 50,000 men from the province of Yunnan. This army was hemmed in by the skill of the Burmans; and, being reduced by the want of provisions, it was afterwards attacked and totally destroyed, with the exception of 2500 men, who were sent in fetters to work in the Burmese capital at their several trades. In the meantime the Siamese revolted, and while the Burman army was marching against them, the Peguan soldiers who had been incorporated in it rose against their companions, and commencing an indiscriminate massacre, pursued the Burman army to the gates of Rangoon, which they besieged, but were unable to capture. In 1774 Tshen-byo-yen was engaged in reducing the marauding tribes. He took the district and fort of Martaban from the revolted Peguans; and in the following year he sailed down the Irawadi with an army of 50,000 men, and, arriving at Rangoon, put to death the aged monarch of Pegu, along with many of his nobles, who had shared with him in the offence of rebellion. He died in 1776, after a reign of twelve years, during which he had extended the Burmese dominions on every side. He was succeeded by his son, a youth of eighteen, called Tsengoomen (Chenguza of Symes), who proved himself a bloodthirsty despot, and was put to death by his uncle, Bhodauphra or Mentaragyi, in 1781, who ascended the vacant throne. In 1783 the new king effected the conquest of Arakán. In the same year he removed his residence from Ava,[1] which, with brief interruptions, had been the capital for four centuries, to the new city of Amarapura, "the City of the Immortals."

The Siamese who had revolted in 1771 were never afterwards subdued by the Burmans; but the latter retained their dominion over the sea-coast as far as Mergui. In the year 1785 they attacked the island of Junkseylon with a fleet of boats and an army, but were ultimately driven back with loss; and a second attempt by the Burman monarch, who in 1786 invaded Siam with an army of 30,000 men, was attended with no better success. In 1793 peace was concluded between these two powers, the Siamese yielding to the Burmans the entire possession of the coast of Tenasserim on the Indian Ocean, and the two important seaports of Mergui and Tavoy.

In 1795 the Burmese were involved in a dispute with the British in India, in consequence of their troops, to the amount of 5000 men, entering the district of Chittagong in pursuit of three robbers who had fled from justice across the frontier. Explanations being made and terms of accommodation offered by General Erskine, the commanding officer, the Burmese commander retired from the British territories, when the fugitives were restored, and all differences for the time amicably arranged.

But it was evident that the gradual extension of the British and Burmese territories would in time bring the two powers into close contact along a more extended line of frontier, and in all probability lead to a war between them. It happened, accordingly, that the Burmese, carrying their arms into Assam and Munnipore, penetrated to the British border near Sylhet, on the N.E. frontier of Bengal, beyond which were the possessions of the chiefs of Cachar, under the protection of the British Government. The Burmese leaders, arrested in their career of conquest, were impatient to measure their strength with their new neighbours. It appears from the evidence of Europeans who resided in Ava, that they were entirely unacquainted with the discipline and resources of the Europeans. They imagined that, like other nations, they would fall before their superior tactics and valour; and their cupidity was inflamed by the prospect of marching to Calcutta and plundering the country. At length their chiefs ventured on the open violation of the British territories. They attacked a party of sepoys within the frontier, and seized and carried off British subjects, while at all points their troops, moving in large bodies, assumed the most menacing positions. In the south encroachments were made upon the British frontier of Chittagong. The island of Shaparee, at the mouth of the Naf river, had been occupied by a small guard of British troops. These were attacked on the 23d September 1823 by the Burmese, and driven from their post with the loss of several lives; and to the repeated demands of the British for redress no answer was returned. Other outrages ensued; and at length, in February 1824, war was declared by the British Government.

Hostilities having commenced, the British rulers in India resolved to carry the war into the enemy's country; an armament, under Commodore Grant and Sir Archibald Campbell, entered the Irawadi River, and anchored off Rangoon on the 10th May 1824. After a feeble resistance this great seaport surrendered, and the troops were landed. The place was entirely deserted by its inhabitants, the provisions were carried off or destroyed, and the invading force took possession of a complete solitude. On the 28th May, Sir A. Campbell ordered an attack on some of the nearest posts, which were all carried after a feeble defence. Another attack was made on the 10th June on the stockades at the village of Kemmendine. Some of these were battered by artillery; and the shot and shells struck such terror into the Burmese that they fled in the utmost precipitation. It soon, however, became apparent that the expedition had been undertaken with very imperfect knowledge of the country, and without adequate provision. The devastation of the country, which was part of the defensive system of the Burmese, was carried out with unrelenting rigour, and the invaders were soon reduced to great difficulties. The health of the men declined, and their ranks were fearfully thinned. The monarch of Ava sent large reinforcements to his dispirited and beaten army; and early in July an attack was commenced on the British line, but proved unsuccessful. On the 8th the British assaulted. The enemy were beaten at all points; and their strongest stockaded works, battered to pieces by a powerful artillery, were in general

[1] The frequent change of capital is quite remarkable in Burmese history. In the earlier periods, it is probable that the chronicles have made it seem more frequent than it is, by running the history of minor contemporaneous kingdoms into that of one great monarchy. But in more recent times the capital has been shifted from Prome to Pagán, from Pagán to Panya, from Panya to Ava, and from Ava to Amarapura; and since the present monarch was visited by the English embassy of 1855, he has caused Amarapura to be abandoned, and has built a new city at Mandalay, which is at present the chief city in the empire.

abandoned. With the exception of an attack by the prince of Sarawadi in the end of August, the enemy allowed the British to remain unmolested during the months of July and August. This interval was employed by Sir A. Campbell in subduing the Burmese provinces of Tavoy and Mergui, and the whole coast of Tenasserim. This was an important conquest, as the country was salubrious and afforded convalescent stations to the sick, who were now so numerous in the British army that there were scarcely 3000 soldiers fit for duty. An expedition was about this time sent against the old Portuguese fort and factory of Syriam, at the mouth of the Pegu River, which was taken; and in October the province of Martaban was reduced under the authority of the British.

The rainy season terminated about the end of October; and the court of Ava, alarmed by the discomfiture of its armies, recalled the veteran legions which were employed in Arakán, under their renowned leader Maha Bandoola, in vain attempts to penetrate the British frontier. Bandoola hastened by forced marches to the defence of his country; and by the end of November an army of 60,000 men had surrounded the British position at Rangoon and Kemmendine, for the defence of which Sir Archibald Campbell had only 5000 efficient troops. The enemy in great force made repeated attacks on Kemmendine without success, and on the 7th December Bandoola was completely routed by Sir A. Campbell. The fugitives retired to a strong position on the river, which they again entrenched; and here they were attacked by the British on the 15th, and driven in complete confusion from the field.

Sir Archibald Campbell now resolved to advance on Prome, about 100 miles higher up the Irawadi River. He moved with his force on the 13th February 1825 in two divisions, one proceeding by land, and the other, under General Cotton, destined for the reduction of Donabew, being embarked on the flotilla. Taking the command of the land force he continued his advance till the 11th March, when intelligence reached him of the failure of the attack upon Donabew. He instantly commenced a retrograde march; on the 27th he effected a junction with General Cotton's force, and on the 2d April carried the entrenchments at Donabew with little resistance, Bandoola having been killed by the explosion of a bomb. The English general entered Prome on the 25th, and remained there during the rainy season. On the 17th September an armistice was concluded for one month. In the course of the summer General Morrison had conquered the province of Arakán; in the north the Burmese were expelled from Assam; and the British had made some progress in Cachar, though their advance was finally impeded by the thick forests and jungle.

The armistice having expired on the 17th October, the army of Ava, amounting to 60,000 men, advanced in three divisions against the British position at Prome, which was defended by 3000 Europeans and 2000 native troops. But the British still triumphed, and after several actions, in which the Burmese were the assailants and were partially successful, Sir A. Campbell, on the 1st December, attacked the different divisions of their army, and successively drove them from all their positions, and dispersed them in every direction. The Burmese retired on Meaday and afterwards on Mellone, along the course of the Irawadi, where they occupied, with 10,000 or 12,000 men, a series of strongly fortified heights and a formidable stockade. On the 26th they sent a flag of truce to the British camp; and a negotiation having commenced, peace was proposed to them on the following conditions:—*1st*, The cession of Arakán, together with the provinces of Mergui, Tavoy, and Yea; *2d*, The renunciation by the Burmese sovereign of all claims upon Assam and the contiguous petty states; *3d*, The Company to be paid a crore of rupees as an indemnification for the expenses of the war; *4th*, Residents from each court to be allowed, with an escort of fifty men; while it was also stipulated that British ships should no longer be obliged to unship their rudders and land their guns as formerly in the Burmese ports. This treaty was agreed to and signed, but the ratification of the king was still wanting; and it was soon apparent that the Burmese had no intention to sign it, but were preparing to renew the contest. On the 19th January, accordingly, Sir A. Campbell attacked and carried the enemy's position at Mellone. Another offer of peace was here made by the Burmese, but it was found to be insincere; and the fugitive army made at the ancient city of Pagán-Myo a final stand in defence of the capital. They were attacked and overthrown on the 9th February 1826; and the invading force being now within four days' march of Ava, Dr Price, an American missionary, who with other Europeans had been thrown into prison when the war commenced, was sent to the British camp with the treaty (known as the Treaty of Yandabo) ratified, the prisoners of war released, and an instalment of 25 lacs of rupees. The war was thus brought to a successful termination, and the British army evacuated the country.

For some years the relations of peace continued undisturbed. Probably the feeling of amity on the part of the Burmese Government was not very strong; but so long as the prince by whom the treaty was concluded continued in power, no attempt was made to depart from its main stipulations. That monarch, Phagyi-dau or Noungdaugyi, however, was obliged in 1837 to yield the throne to a usurper who appeared in the person of his brother, Kounboungmen or Tharawadi. The latter, at an early period, manifested not only that hatred of British connection which was almost universal at the Burmese court, but also the extremest contempt. For several years it had become apparent that the period was approaching when war between the British and the Burmese Governments would again become inevitable. The British resident, Major Burney, who had been appointed in 1830, finding his presence at Ava agreeable neither to the king nor to himself, removed in 1837 to Rangoon, and shortly afterwards retired from the country. Ultimately it became necessary to forego even the pretence of maintaining relations of friendship, and the British functionary at that time, Captain Macleod, was properly withdrawn, in 1840, altogether from a country where his continuance would have been but a mockery. The state of sullen dislike which followed was after a while succeeded by more active evidences of hostility. Acts of violence were committed on British ships and British seamen. Remonstrance was consequently made by the British Government, and its envoys were supported by a small naval force. The officers on whom devolved the duty of representing the wrongs of their fellow-countrymen and demanding redress, proceeded to Rangoon, the governor of which place had been a chief actor in the outrages complained of; but so far were they from meeting with any signs of regret, that they were treated with indignity and contempt, and compelled to retire without accomplishing anything beyond blockading the ports. A series of negotiations followed; nothing was demanded of the Burmese beyond a very moderate compensation for the injuries inflicted on the masters of two British vessels, an apology for the insults offered by the governor of Rangoon to the representatives of the British Government, and the re-establishment of at least the appearance of friendly relations by the reception of a British agent by the Burmese Government. But the obduracy of the king—known as the Pagán-men, who had succeeded his father in 1846—led to the refusal alike of atonement for past wrongs, of any expression of regret for the display of

gratuitous insolence, and of any indication of a desire to maintain friendship for the future. Another Burmese war was the result, the first shot being fired in January 1852. As in the former, though success was varying, the British finally triumphed, and the chief towns in the lower part of the Burmese kingdom fell to them in succession. The city of Pegu, the capital of that portion which, after having been captured, had again passed into the hands of the enemy, was recaptured and retained, and the whole province of Pegu was, by proclamation of the Governor-General, Lord Dalhousie, declared to be annexed to the British dominions on the 20th December 1852. No treaty was obtained or insisted upon,—the British Government being content with the tacit acquiescence of the king of Burmah without such documents; but its resolution was declared, that any active demonstration of hostility by him would be followed by retribution.

About the same time a revolution broke out which resulted in Pagán-men's dethronement. His tyrannical and barbarous conduct had made him obnoxious at home as well as abroad, and indeed many of his actions recall the worst passages of the history of the later Roman emperors. The prince of Mendoon, who had become apprehensive for his own safety, made him prisoner in February 1853, and was himself crowned king of Burmah towards the end of the year. The new monarch, known as Mendoon-men, has shown himself sufficently arrogant in his dealings with the European powers, but has been wise enough to keep free from any approach towards hostility, and, indeed, has latterly displayed a desire to live on peaceful terms with the Indian Government. The loss of Pegu was long a matter of bitter regret, and he absolutely refused to acknowledge it by a formal treaty. In the beginning of 1855 he sent a mission of compliment to Lord Dalhousie, the Governor-General; and in the summer of the same year Major Arthur Phayre, *de facto* governor of the new province of Pegu, was appointed envoy to the Burmese court. He was accompanied by Captain (now Colonel) Henry Yule as secretary, and Mr Oldham as geologist, and his mission added largely to our knowledge of the state of the country; but in its main object of obtaining a treaty it was unsuccessful. It was not till 1862 that the king at length yielded, and his relations with Britain were placed on a definite diplomatic basis. Much interest has been taken of recent years in the restoration of the trade between China and British Burmah by the old routes overland, and various important journeys in elucidation of the problem have been successfully undertaken. In 1863 Dr Clement Williams, at that time resident in the capital, received the king's permission to proceed to Bhamo, and safely accomplished his voyage to the upper defile of the Irawadi beyond that town in the months of January and February. His recall to the capital prevented his further advance.

In 1867 a treaty was signed by which British steamers were permitted to navigate Burmese waters, and the appointment of British agents at Bhamo or other stations for the collection of customs was formally authorized, and in the following year a Government expedition, consisting of Captain Williams as engineer, Dr Anderson as naturalist, and Captain Bowers and Messrs Stewart and Burn as representatives of the commercial interest of Rangoon, was despatched under the leadership of Major Sladen, political resident at Mandalay. The royal steamer *Yaynan-Sekia*, or "The Honesty," was placed by the king at the service of the expedition, and letters of recommendation were furnished to the Burmese officials, but in other respects scant courtesy was shown to the party. Escorted by fifty armed police, the explorers advanced in safety about 135 miles north-east of Bhamo to Momien or Teng-yue-Chow, a principal town of the Mahometan insurgents, known to the Burmese as Panthés; but beyond this it was considered imprudent to proceed on account of the disturbed condition of the country. In 1869 Captain Storer was appointed first British resident at Bhamo; and about the same time the Irawadi Flotilla Company started a monthly steamer service to that town, which has now become almost fortnightly. The king's interest in the commercial development of his country was shown by his erecting and garrisoning a series of guardhouses through the dangerous parts of the Kakhyen hills. In 1874 Lord Salisbury sent another expedition, consisting of Colonel Horace Browne, Mr Ney Elias, and Dr Anderson, with instructions to proceed, if possible, right across the country to Shanghai in China; and to ensure the success of the undertaking, Mr Margary, a gentleman familiar with the Chinese language and customs, was commissioned to start from Shanghai and meet the party at Momien or the neighbourhood. The king's reception of the new mission, which arrived on December 23, 1874, at Mandalay, was favourable in the extreme. On the 15th of January 1875 the explorers reached Bhamo; and two days afterwards Mr Margary arrived from Hankow. After the mission had proceeded to the banks of the Nampoung, a river which joins the Tapeng some distance east of Ponline, they heard rumours of hostile preparations in front; and Mr Margary volunteered to proceed to Manwyne to find the truth of the reports. On receiving from him word that the way was clear, his companions advanced; but on the 23d of February their camp was attacked by the Chinese, and they were ultimately compelled to retreat with the sad knowledge that their gallant pioneer had fallen at Manwyne by the hands of cowardly assassins. The Burmese officials stood nobly by the mission, though the enemy assured them that their quarrel was not with them but with the "white devils." Some fears have been entertained of disagreements between the court of Mandalay and the British authorities, partly in regard to the allegiance of some Karen tribes, and partly in connection with the claim for a right of way for British troops through the Burmese dominions in case of active measures being required to obtain redress from the Chinese Government for the murder of Mr Margary. Happily these fears have been disappointed; the mission of Sir Douglas Forsyth has come to a peaceful if not altogether a successful termination, and a commission has been formed to settle the Karen boundary. While a certain amount of suspicion in regard to British policy still remains in the king's mind, he seems more and more disposed to co-operate with his European allies, and shows himself friendly to the European residents in his capital. His reign has been several times disturbed by internal dissensions, and the general condition of the country can hardly be regarded as one of stability. Personally he is an orthodox and devoted Buddhist, and is largely under the influence of ecclesiastical advisers. In 1874 he was recrowned at Mandalay, in compliance with the requirements of a prophecy, and he attempts to enforce stringent sumptuary laws in accordance with his creed. It is satisfactory to know that while some of his officials are undoubtedly hostile to European interests, the great mass of the people seem genuinely favourable.

BURMAH, British, the country acquired by the British Indian Government after the two wars with the Burman empire, is situated between 10° and 22° N. lat., and 92° and 100° E. long. It is bounded on the N. by Independent Burmah, on the E. by Siam, on the S. by the Indian Ocean, and on the W. by the Bay of Bengal and the *Chittagong* division of Bengal. The province of British Burmah extends along the eastern shore of the Bay of Bengal, and is geographically divided into four portions,—Arakán, extending from the Náf estuary to Cape Negrais, and consisting of a narrow strip of country between the sea and the high mountain chain called Yoma; the valley of the Irawadi, which, divided from the Sittang valley by the Pegu Yoma range, unites with it in its southern portion; the valley of the Salwin; and Tenasserim, a narrow strip, separated from Siam by a lofty chain of hills running from north to south. For administrative purposes the country is divided into three commissionerships, Arákán, Pegu, and Tenasserim, and into fifteen districts, viz., Akyab, Ramree, Sandoway, Northern Arákán, Rangoon, Bassein, Myanoung, Prome, Thayet-myo, Toungoo, Shwegyen, Amherst, Tavoy, Mergui, and Salwin.

Physical Aspects.—The greater part of the province is covered with hills, forests, estuaries, and river beds. The eastern and southern part is particularly mountainous, thinly populated, and much intersected by streams. In the central part of the province the valley of the Irawadi unites with the valley of the Sittang at its lower end, and forms an extensive plain, stretching from Cape Negrais on the west to Martaban on the east. The more northern of these valleys are rugged and hilly, and are so densely covered with jungle that but little cultivation can be carried on. A chain of mountains called the Yoma range forms the boundary of the Arakán division on the east. It is the continuation of the Pátkoi and Baráil range, which shoots forth from the Himálayas at their north-eastern extremity, runs south, forms the eastern boundary of Assam and Bengal, and turning south-east, gradually diminishes both in breadth and elevation till it ends in the rocky promontory of Cape Negrais. Blue Mountain, one of its peaks, on the northern boundary of the province, is said to rise 8000 feet above the sea-level; but within the province the range nowhere attains a height much above 4000 feet. The same Yoma range forms the western boundary of the Irawadi valley; and the Poung Loung range, rising to a supposed height of 7000 feet, bounds the Sittang valley towards the east The Pegu Yoma range forms the watershed between these two streams. The mountains of Tenasserim rise to a height of 5000 feet, with a breadth varying from 10 to 40 miles; they are covered with pathless jungle, and devoid of human habitations of any kind.

Rivers.—Beginning from the extreme west the following are the principal rivers:—The Náf estuary is on the western boundary. The Mroo River, an arm of the sea, about 40 miles to the eastward, is from 3 to 4 miles broad at its mouth. The Koladan or Arakán River rises near the Blue Mountain in about 23° N. lat., and is navigable for 40 miles from its mouth by vessels of 300 or 400 tons burden. The Talak, Aeng, Sandoway, Toungoop, and Gwa are streams of minor importance. The mouth of the last, however, forms a good port and haven for steamers or vessels of from 9 to 10 feet draught. The Irawadi rises in about 28° N. lat. and 97° 30′ E. long., and flows for upwards of 600 miles before reaching the British possessions, through which it has a course of 240 miles to the sea in a S.S.W. the;tion. As it approaches the coast it divides into numenegot ranches, converting the lower portion of the valley on the et-work of tidal creeks. Its principal branches are togethesein River, Thekkay-thoung, Yuay, Dayaybhyoo, 2*l*, Thaloo, Pyengazaloo. Dalla, Phyapoon, Donyan, Thanaupon teat, and China Buckir rivers. It is navigable for river steamers as far as Bhamo, nearly 400 miles beyond the British frontier. The river when full runs about five miles an hour. The Hleing rises close to Prome, where it is called the Myitmakat stream, and flowing in a southerly direction nearly parallel to the Irawadi, it next takes the name of the Hleing, and finally of the Rangoon River, and falls into the sea a few miles below Rangoon. Its principal tributaries are the Nyoungdon, an offshoot of the Irawadi, and the Pegu and Poozoondoung rivers. It is navigable by vessels of the largest size for some distance above Rangoon, but owing to the Hastings shoal, formed at the junction of the Pegu, the Poozoondoung, and the Rangoon rivers, vessels of more than 6 feet draught cannot ascend beyond the shoal at low tide. The Sittang River rises far north of British territory, which it enters just about Toungoo, and flowing southwards, falls into the Gulf of Martaban, when it widens so rapidly that it is impossible to tell where the river ends and the gulf begins. Its principal tributary is the Shwegyen River. A bore, or tidal wave, sweeps up this river, and its effect is felt as far as Shwegyen town. The Biling River rises in the Poungloung hills, flows southward, and falls into the Gulf of Martaban. The Salwin River rises in Tibet, flows south through the Shan states, and falls into the sea at Moulmein. The Attaran rises in the chain of hills which forms the boundary between the kingdom of Siam and British Burmah, and flows in a south-westerly direction through dense teak forests and an almost uninhabited country. The Gyne has numerous villages on its banks, and is navigable for 180 miles by country boats. The Tenasserim River falls into the sea by two mouths, the northern of which is navigable for large ships.

There is only one canal in the province, connecting the Pegu and the Sittang rivers. The lakes are the Thoo, Lahgyin, and Kandaugyee.

A large part of the province is covered with forests, but the state reserved area only amounts to 133 square miles. The teak plantations lie in the Rangoon division. The total receipts from the forests in 1871–72 amounted to £77,240.

Population.—The total area of the province is 88,556 square miles; the population was returned by the census of 1872 at 2,747,148, giving an average of 31 inhabitants to the square mile. The Buddhists numbered 2,447,831, Mahometans 99,846, Hindus 36,658, Christians 52,299, and aborigines 110,514. The villages, townships, &c., numbered 14,107; the inhabited houses, 535,533. Only ten towns in the province had a population exceeding 10,000,—Rangoon, the capital, containing 98,745.

Productions.—Rice is the staple product of the province, and in 1871–72 1,836,021 acres were devoted to its cultivation. Other food grains covered 4860 acres; sesamum, 25,502 acres; sugar-cane, chiefly cultivated in the gardens around the cultivators' houses, 3179 acres; and cotton, principally grown in the hill clearings, 14,120 acres. The fibre of the indigenous cotton is short, but strong, and it adheres with great tenacity to the seed. The export of cotton is increasing. Tobacco, grown on sandbanks or in the dry beds of streams, inferior in quality, and wholly used for home consumption, occupied 12,866 acres. The other crops produced in the province are indigo, vegetables, hemp, mixed fruits, &c. The system of cultivation known in Bengal as the *júm*, that is clearing virgin soil by burning, cultivating it for one or two years, and then leaving it again to the jungle, is here extensively practised under the name of *toungya* cultivation. Although discouraged on account of its wasteful character it cannot be altogether prohibited, as it is the only means of subsistence for a large part of the population. Seven great embankments have been constructed in the province for the protection and extension

of regular cultivation. The average rent per acre of rice land varies from 1s. to 10s., while the high land, on which other grains can be cultivated, fetches generally from 3s. to 4s. per acre. Of the total area of the province (88,556 square miles) only 3414 square miles are cultivated; 51,117 square miles are cultivable, and the rest uncultivable waste

Internal Communication is chiefly carried on by water. Steamers ply on the Irawadi between Thayetmyo, Prome, Myanoung, Henzada, and Rangoon. There is also steam communication from Calcutta, *via* Akyab, to Rangoon and Moulmein, and between Tavoy and Mergui. There were, however, 814 miles of road in the province in 1871–72.

Mines.—The only mines in the province are those worked for tin in the southern portion of the Tenasserim division. This mineral (a binoxide) exists over a large extent of country in the Mergui and Tavoy districts, and is obtained by removing and washing the pebble and boulder deposits of the river beds Samples of the tin-stone, once washed, have produced about 70 per cent. of metal, and twice washed 75 per cent. The ore is therefore very rich, and the metal produced is of excellent quality. Hitherto these deposits have been washed by Chinese and natives of the country in a very rough and unscientific manner, and the tin-stone is smelted in a most primitive way, the produce realized being 68 per cent. of metal. European capitalists have now begun to turn their attention to the subject, and arrangements are being made to lease out certain tracts. Coal exists on the banks of the Tenasserim River, and in other parts of the province, but it has never been worked to any extent. Lead has been found in Toungoo, and on Maingay's Island in the Mergui Archipelago, but nothing has been done towards utilizing it. This mineral also exists in the Shwegyen district, as well as gold, antimony ore, and iron-stone. The quantity of the precious metals is, however, very small, and the workers make but a poor living Limestone exists in several parts of the province, and quarries are worked pretty extensively in Thayetmyo and Bassein; stone might also be excavated in Sandoway if a demand existed.

Manufactures.—Mills are employed in the seaport towns for husking rice and for sawing timber. There were in 1871–72 twenty-six steam rice mills in the province; five years before there were only three; and the number rapidly increases with the demand for rice for shipment to Europe, to the Straits, and to China. Silk and cotton goods are manufactured in large quantities, chiefly, however, for home use, and by small hand-looms. A loom forms a regular piece of furniture in a Burmese household; it is worked by the female members of the family. The cotton cloths thus manufactured are rough but strong; some of the silk goods fetch a high price. A coarse description of salt is made on the sea-coast, used chiefly in the preparation of *Ngapee* (a mess of half-salted, half-decomposed fish and other ingredients), which forms a favourite article of food among the Burmese. The manufacture of salt has lately fallen off, owing to the introduction of Liverpool salt, which undersells the local article. The other manufactures of the province consist of gold and silver bowls (of peculiar and elaborate workmanship), lacquered ware, carved and gilt work, and dyes, especially cutch, an extract of the *Acacia Catechu*.

Trade.—The total value of the trade of the province in 1871–72 was £10,777,705; exports, £5,452,148; imports, £5,325,557. The value of the sea-borne trade was—exports, £4,236,997; imports, £4,220,723—total, £8,457,721; and of the inland trade—exports, £1,245,150; imports, £1,104,832. The most important article of sea-borne exports is rice. The trade increased from 380,009 tons in 1865 to 470,893 tons in 1871, and made a sudden rise to 700,784 tons in 1872. Next in importance is the timber trade, shipments of which during the year 1872 amounted to 87,545 tons, of the value of £51,210. The other articles of export are cotton, cutch, hides, horns, ivory, jade stone, petroleum, rice and paddy, precious stones, stick-lac, tobacco, &c. The articles of import consist of betel-nut, cotton twist and yarn, crockery ware, cutlery, gunny bags, hardware; cotton, silk, and woollen piece goods; raw silk, spirituous liquors wines, beers, &c., sugar and tobacco.

Finances.—The gross revenue from all sources in 1871–72, £1,363,452, of which £1,217,053 was from imperial taxation, £37,320 for provincial services, and £109,079 from local funds. The land revenue of the province was £344,523. Owing to the sparse population and vast extent of country cultivable but uncultivated, the rates of assessment range low. No class of landed proprietors, like the zamindars of Bengal, exists in Burmah. The cultivators themselves hold the land from Government, the extent of their holdings averaging about 5 acres. The exceptions are, where grants of waste land have been made to Europeans or natives of India, but such grants are but little cultivated. The light land tax of the province is supplemented by a capitation tax, peculiar to Burmah; and by the rice duty, which, from the circumstances of the local trade, falls on the producer, and is equivalent to a tax of 14 per cent. *ad valorem* on this article of export. The capitation tax is a poll-tax on the male population of the province, from 18 to 60 years of age, with the exception of immigrants during the first five years of their residence, religious teachers, schoolmasters, Government servants, and those unable to obtain their own livelihood. In 1871–72 it was levied on 556,035 persons, and yielded a revenue of £226,954. The expenditure on the civil administration of the province in 1871–72 was £497,002. For the protection of British Burmah 5016 fighting men, Europeans and natives, were maintained in 1871 at a total cost of £276,200. The strength of the police in 1871 was 5319. The prisons consist of two great central gaols, Rangoon and Moulmein, chiefly for long-term convicts, with twelve subordinate gaols and lock-ups.

Education has not made much progress in British Burmah under the English plan of public instruction; but the people have a wide-spread system of primary education of their own in the monastic schools. Setting aside these monastic schools, the educational machinery of the province consists of seven Government schools, educating 505 boys; fifteen aided missionary schools, teaching 1494 pupils; and twenty-two other unaided schools under Government inspection, teaching 499 pupils.

Christianity has spread largely among the Karen tribes, chiefly through the work of American missions

Climate.—The climate of British Burmah is moist and depressing for part of the year, but cooler than that of India. Some of the forest tracts during the monsoons, and after the cold weather has set in, are impregnated with deadly malaria; but the coast and the frontier ranges are not unhealthy. The prevalent complaints amongst Europeans are fever, dysentery, and hepatic diseases, from which the natives also suffer. On the whole, however, the climate of British Burmah seems better adapted to the European constitution than any part of India, and of late the statistics of the British troops show a very low rate of disease and mortality. The rainfall varied in 1871 from 245·85 inches at Moulmein to 54·85 inches at Thayetmyo. The average temperature is greatly affected by the sea breeze,—being 80° Fahr. at the sea-coast, and 90° in the interior.

Form of Government.—The highest authority in the province of British Burmah is the chief commissioner and agent to the Governor-General of India, established under a resolution of the Government of India, dated January

1862. The chief commissioner is assisted by a secretary and assistant-secretary, three commissioners of revenue and circuit, thirteen deputy-commissioners, one superintendent of *hill-tracts*, *twenty-two assistant-commissioners*, *four* collectors of sea-customs a director of public instruction, an inspector-general of police, an inspector-general of prisons, and a conservator of forests. *A political agent is established* at the court of Mandalay, and an assistant political agent at Bhamo, for facilitating British trade with Independent Burmah and China. The judicial officers are—the recorder of Rangoon, the judicial commissioner, the judge of the town of Moulmein, the judge of the Small Cause Court, Rangoon, and three town magistrates. For history, see the preceding article.

BURMANN, Pieter (1668–1741), a Dutch classical scholar, was born at Utrecht on the 26th June 1668. He was educated at the public school in his native place, and at the age of thirteen entered the university. He devoted himself particularly to the study of the classical languages, and became unusually proficient in Latin composition. As he was intended for the legal profession he spent some years in attendance on the law classes. For about a year he studied at Leyden, paying special attention to philosophy and Greek. On his return to Utrecht he took the degree of doctor of laws (March 1688), and after travelling through Switzerland and part of Germany, settled down to the practice of law. In December 1691 he was appointed receiver of the tithes which were originally paid to the bishop of Utrecht, and five years later he was nominated to the professorship of eloquence and history. To this chair was soon added that of Greek and politics. In 1714 he paid a short visit to Paris and ransacked the libraries, bringing back a "great treasure of useful observations." In the following year he was appointed successor to the celebrated Perizonius, who had held the chair of history, Greek language, and eloquence at Leyden. His numerous editorial and critical works spread his fame as a scholar throughout Europe, and engaged him in many of the stormy disputes which were then so common among men of letters. He died on the 31st March 1741.

Of his editions of classical works the following may be noted:—*Phaedrus*, 1695; *Horace*, 1699; *Valerius Flaccus*, 1701; *Petronius Arbiter*, 1709; *Velleius Paterculus*, 1719; *Quintilian*, 1720; *Ovid*, 1727; *Lucan*, 1740. He also published an edition of Buchanan's works, continued Graevius's great work, *Thesaurus Antiquitatum et Historiarum Italiae*, and wrote a small manual of Roman antiquities, *Antiquitatum Romanarum Brevis Descriptio*, 1711. His poems and orations were published after his death.

BURNES, ... by the Royal Geographical Society of London, but also by that of Paris. Soon after his return to India in 1835 he was appointed to the court of Sindh to secure a treaty for the navigation of the Indus; and in 1836 he undertook a political mission to Dost Mohammed at Cabul. On the restoration of Shah Shujah in 1839, he became regular political agent at Cabul, and remained there till his assassination in 1841 (November 2), during the heat of an insurrection. The calmness with which he continued at his post, long after the imminence of his danger was apparent, gives an heroic colouring to the close of an honourable and devoted life. A narrative of his later labours was published in 1842 under the title of *Cabool*.

BURNET, Gilbert (1643–1715), bishop of Salisbury, was born at Edinburgh in 1643, and was descended of an ancient family of the county of Aberdeen. His father had been bred to the law, and was at the Restoration appointed one of the lords of Session, with the title of Lord Crimond. Gilbert, the youngest son, was at ten years of age sent to Marischal College, Aberdeen, where he was admitted A.M. before he was fourteen years of age. His own inclination led him to the study of the civil and feudal law; but he afterwards changed his views, and, to the great satisfaction of his father, began to apply to divinity. He received ordination before the age of eighteen; and Sir Alexander Burnet, his cousin-german, offered him a benefice, which, however, he refused to accept.

In 1663, about two years after the death of his father, he went to England; and after six months stay at Oxford and Cambridge, returned to Scotland, which he soon left again to make a tour of some months, in 1664, in Holland and France. At Amsterdam, by the help of a Jewish rabbi, he perfected himself in the Hebrew language; and likewise became acquainted with the leading men of the different persuasions tolerated in that country—Calvinists, Arminians, Lutherans, Anabaptists, Brownists, Papists, and Unitarians. In each of these sects he used frequently to declare he met with men of such unfeigned piety and virtue that he became fixed in a strong principle of universal charity, and an invincible abhorrence of all severities on account of religious dissensions.

Upon his return from his travels he was admitted minister of Saltoun, in which station he served five years in the most exemplary manner. He drew up a memorial, in which he took notice of the principal errors in the conduct of the Scottish bishops, which he observed not to be conformable to the primitive institution, and he sent a copy of it to several of them. This exposed him to their resentment; but to show he was not actuated by a spirit of ambition, he led a retired course of life for two years, which so endangered his health that he was obliged to abate his excessive application to study. In the year 1668 he was appointed professor of divinity in the university of Glasgow; and, according to the usual practice, he read his lectures in the Latin language. It was apparently at this period that he laid the chief foundation of that theological learning for which he became so distinguished. In 1669 he published his *Modest and Free Conference between a Conformist and Nonconformist*. He became acquainted with the duchess of Hamilton, who communicated to him all the papers belonging to her father and her uncle; upon which he drew up the *Memoirs of the Dukes of Hamilton*, afterwards printed at London, in folio, in the year 1677. The duke of Lauderdale, hearing that he was engaged in this work, invited him to London, and introduced him to Charles II. He returned to Scotland, and married Lady Margaret Kennedy, daughter of the earl of Cassillis, a lady of great knowledge, and highly esteemed by the Presbyterians, to whose sentiments she was strongly inclined. As there was some disparity in their ages, that it might be

sufficiently evident that the match was wholly owing to inclination, and not to avarice or ambition, the day before their marriage he delivered to the lady a deed, by which he renounced all pretensions to her fortune, which was very considerable, and must otherwise have fallen into his hands, she herself having no intention to secure it. His *Vindication of the Authority, Constitution, and Laws of the Church and State of Scotland* was printed at Glasgow, in 8vo, in the year 1673. This was considered so material a service to the Government, that he was offered a bishopric, with a promise of the next vacant archbishopric; but he did not accept of it, because he could not approve of the measures of the court, the great aim of which he perceived to be the advancement of popery. The publication itself was one of those which the author could not afterwards recollect with much satisfaction.

His intimacy with the dukes of Hamilton and Lauderdale procured him frequent messages from the king and the duke of York, who had conversations with him in private. But Lauderdale, who was the most unprincipled man of the age, conceiving a resentment against him on account of the freedom with which he spoke to him, represented at last to the king that Dr Burnet was engaged in an opposition to his measures; and on his return to London he perceived that these suggestions had entirely deprived him of the king's favour, though the duke of York treated him with greater civility than ever, and dissuaded him from going to Scotland. He accordingly resigned his professorship at Glasgow, and settled in London. About this time the living of Cripplegate being vacant, the dean and chapter of St Paul's (in whose gift it was), hearing of his circumstances, and the hardships which he had undergone, made him an offer of the benefice; but, as he had been informed of their first intention of conferring it on Dr Fowler, he generously declined it. In 1675, at the recommendation of Lord Hollis, whom he had known in France as ambassador at that court, he was appointed preacher at the Rolls chapel, by Sir Harbottle Grimstone, master of the rolls, notwithstanding the opposition of the court; and he was soon afterwards chosen lecturer at St Clement's, and became one of the most popular preachers in town. The first volume of his *History of the Reformation of the Church of England* was published in folio in 1681, the second in 1683, and the third in 1715. For this great work he received the thanks of both Houses of Parliament. Of the first two volumes he published an abridgment in the year 1683.

In 1682, when the administration was changed in favour of the duke of York, being much resorted to by persons of all ranks and parties, in order to avoid returning visits, he built a laboratory, and for above a year pursued a course of chemical experiments. Not long after he refused a country living of £300 a year offered him by the earl of Essex on condition that he should reside in London. When the inquiry concerning the popish plot was on foot he was frequently sent for and consulted by the king, who offered him the bishopric of Chichester, then vacant, if he would engage in his interests; but he refused to accept it on these terms. He preached at the Rolls till 1684, when he was dismissed by order of the court.

On the accession of James II. to the throne, having obtained leave to quit the kingdom, he first went to Paris, and lived in great retirement, till, contracting an acquaintance with Brigadier Stouppe, a Protestant gentleman in the French service, he made a tour with him into Italy. He met with an agreeable reception at Rome. Pope Innocent XI. hearing of his arrival, sent the captain of the Swiss guard to acquaint him he would give him a private audience in bed, to avoid the ceremony of kissing his holiness's slipper; but Dr Burnet excused himself as well as he could. Here, with more zeal than prudence, he engaged in some religious disputes; and, on receiving an intimation from Prince Borghese, he found it necessary to withdraw from this stronghold of priestcraft, and pursued his travels through Switzerland and Germany. He afterwards came to Utrecht, with an intention to settle in some of the seven provinces. There he received an invitation from the prince and princess of Orange (to whom their party in England had recommended him) to come to the Hague, and accepted the invitation. He was soon made acquainted with the secret of their councils, and advised the preparation of a fleet in Holland sufficient to support their designs and encourage their friends. His known share in the councils of the Prince of Orange, and the pamphlets which he sent over to England, excited against him the intensest enmity of James. A prosecution for high treason was commenced against him both in England and Scotland; but having received the intelligence before it was announced to the States he avoided the storm by petitioning for, and obtaining without any difficulty, a bill of naturalization, in order to his intended marriage with Mary Scott, a Dutch lady of considerable fortune.

Being now legally under the protection of Holland, he omitted no opportunity of supporting and promoting the design which the prince of Orange had formed of delivering Great Britain; and, having accompanied him in the capacity of chaplain, he was in the year 1689 advanced to the see of Salisbury. He declared for moderate measures with regard to the clergy who scrupled to take the oaths, and many were displeased with him for advocating the toleration of Nonconformists. "As my lord of Salisbury," says the earl of Shaftesbury, "has done more than any man living for the good and honour of the Church of England and the Reformed religion, so he now suffers more than any man from the tongues and slander of those ungrateful churchmen; who may well call themselves by that single term of distinction, having no claim to that of Christianity or Protestant, since they have thrown off all the temper of the former, and all concern or interest with the latter." The same noble writer has elsewhere mentioned him in the following terms of commendation:—"The bishop of Salisbury's *Exposition of the Articles* is, no doubt, highly worthy of your study. None can better explain the sense of the church than one who is the greatest pillar of it since the first founders,—one who best explained and asserted the Reformation itself, was chiefly instrumental in saving it from Popery before and at the Revolution, and is now the truest example of laborious, primitive, pious, and learned episcopacy."[1]

In 1693, after the publication and condemnation of Blount's anonymous pamphlet, *King William and Queen Mary Conquerors* (see BLOUNT), an opportunity was taken by Burnet's enemies to bring a pastoral letter of his before the House of Commons. After a warm discussion the letter was condemned to be burned by the common hangman.

In 1698 he lost his wife by the small-pox; and as he was almost immediately after appointed preceptor to the duke of Gloucester, of whose education he took great care, this employment, and the tender age of his children, induced him the same year to supply her loss by a marriage with Mrs Berkeley, a widow, who was eldest daughter of Sir Richard Blake. In 1699 he published his *Exposition of the Thirty-nine Articles*, which occasioned a charge against him in the Lower House of Convocation in the year 1701, but he was vindicated in the Upper House. His speech in the House of Lords in 1704 against the Bill to prevent occasional conformity was severely attacked. He

[1] Shaftesbury's *Letters*, p. 28, 37.

formed a scheme for augmenting the small livings, which he pressed forward with such success, that an Act of Parliament was passed in the second year of Queen Anne, for the augmentation of the livings of the poor clergy. He died in 1715, and was interred in the church of St James's, Clerkenwell, where a monument was erected to his memory.

Bishop Burnet's *History of his Own Time*, consisting of two large volumes in folio, was not published till several years after the author's death; the first volume appeared in 1724, and the second in 1734. An account of his life was added by his youngest son Sir Thomas Burnet, one of the judges of the Court of Common Pleas. The *History* itself was not printed without mutilations; but after an interval of nearly a century, an edition containing all the passages which had formerly been suppressed, was published under the superintendence of the learned Dr Routh. (Oxford, 1823, 6 vols. 8vo.) This is a work of great and intrinsic value; without it our knowledge of the times would be exceedingly imperfect. His materials are not always very carefully digested, and the style is sometimes supposed to be too familiar; but these defects are abundantly compensated for by the copiousness of his information, the benevolence of his sentiments, and the earnestness of his manner. In general Burnet's statements may be accepted with great confidence, his judgment is always sound and sober, and he possesses considerable skill in the delineation of character. The best editions of his two great works are—*History of his Own Time*, 6 vols., Oxford, 1833; *History of the Reformation*, 7 vols., by N. Pocock, 1865.

Besides the works mentioned above the following are worthy of notice:—*Some Passages of the Life and Death of John Earl of Rochester*,[1] Lond. 1680, 8vo; *The Life and Death of Sir Matthew Hale, Kt., sometime Lord Chief-Justice of his Majestie's Court of Kings Bench*, Lond. 1682, 8vo; *The History of the Rights of Princes in disposing of Ecclesiastical Benefices and Church Lands*, Lond. 1682, 8vo; *The Life of William Bedell, D.D., Bishop of Kilmore in Ireland*, Lond. 1685, 8vo; *Reflections on Mr Varillas's "History of the Revolutions that have happened in Europe in matters of Religion," and more particularly on his Ninth Book, that relates to England*, Amst. 1686, 12mo; *A Defence of the Reflections on the Ninth Book of the first volume of Mr Varillas's "History of Heresies," being a Reply to his Answer*, Amst. 1687, 12mo; *A Continuation of Reflections on Mr Varillas's "History of Heresies," particularly on that which relates to English Affairs in his Third and Fourth tomes*, Amst. 1687, 12mo. He took a very conspicuous part in the continued controversy which was in his time maintained against the papists; and a complete catalogue of his polemical works would occupy no small space. The following translations deserve to be mentioned:—*Utopia, written in Latin by Sir Thomas More, Chancellor of England: translated into English*, Lond. 1685, 8vo; *A Relation of the Death of the Primitive Persecutors, written originally in Latin, by L. C. F. Lactantius: Englished by Gilbert Burnet, D.D., to which he hath made a large preface concerning Persecution*, Amst. 1687, 12mo.

BURNET, Thomas (1635–1715), best known as the author of *The Sacred Theory of the Earth*, was born at Croft in Yorkshire about the year 1635, but is supposed to have been descended of a Scottish family. He was educated at the free school of Northallerton, and in June 1651 was admitted a pensioner of Clare Hall at Cambridge, under the tuition of Tillotson, who continued to remember him with kindness. In the year 1654 he removed to Christ's College, on the election of Dr Cudworth to the mastership, and there he obtained a fellowship in the year 1657. In 1661 he became senior proctor of the university. He was successively domestic tutor to Charles duke of Bolton, and to James earl of Ossory, afterwards duke of Ormond, grandson to the first duke; and by the interest of the latter nobleman he was chosen master of the Charterhouse in 1685. Among the electors some of the bishops opposed him on account of his wearing a lay habit; but the duke was satisfied that he possessed the more essential qualifications of a life and conversation suitable to his clerical character. After this appointment he took the degree of D.D. In his capacity of master he made a noble stand against the illegal attempts to admit Andrew Popham as a pensioner of the house, strenuously opposing an order of the 26th of December 1686, addressed by James II. to the governors dispensing with the statutes for the occasion.

Dr Burnet published his *Telluris Theoria Sacra*, or *Sacred Theory of the Earth*, at London in 1681. This work, containing a fanciful theory of the earth's structure, attracted an unusual share of public attention, and he was afterwards encouraged to issue an English translation, which was printed in folio, 1684–1689. Addison commended the author in a Latin ode, but his theory was attacked by Dr Keill, Mr Whiston, and Mr Warren, to all of whom he returned answers. His reputation obtained for him an introduction at court by Archbishop Tillotson, whom he succeeded as clerk of the closet to King William. He seemed already to be on the direct road to much higher preferment, when he suddenly marred his prospects by the publication, in 1692, of a work entitled *Archæologiæ Philosophicæ: sive Doctrina antiqua de Rerum Originibus*, in which he treated the Mosaic account of the fall of man as an allegory. The method of treatment excited a great clamour against him; and the king was obliged to remove him from his office at court. Of this book an English translation was executed by Mr Foxton, Lond. 1729, 8vo. Dr Burnet published several other minor works before his death, which took place at the Charter-house on the 27th September 1715. Two posthumous works were published several years after his death—*De Fide et Officiis Christianorum*, 1723, and *De Statu Mortuorum et Resurgentium Tractatus*, 1723; in which he maintained the doctrine of a middle state, the millennium, and the limited duration of future punishment. A *Life of Dr Burnet* by Heathcote appeared in 1759.

BURNETT, James, Lord Monboddo. See Monboddo.

BURNEY, Charles, Doctor of Music (1726–1814), was born in the ancient city of Shrewsbury, the capital of Shropshire, on the 7th of April 1726. He received his earlier education at the excellent free school of that city, and was afterwards sent to the public school at Chester. His first music master was Mr Baker, organist of Chester Cathedral, and a pupil of Dr John Blow. Returning to Shrewsbury when about fifteen years old, he continued his musical studies for three years under his half-brother, Mr James Burney, organist of St Mary's Church, and was then sent to London as a pupil of the celebrated Dr Arne, with whom he remained three years. In 1749 he was appointed organist of a church in the city, with a salary of £30 a year; and he was also engaged as conductor of a concert established at the King's Arms, Cornhill. In that year and the next he composed the music of three dramas for Drury Lane theatre—*Alfred*, *Robin Hood*, and *Queen Mab*. Being threatened with a pulmonary affection he went, on the advice of his physician, in 1751 to Lynn, in Norfolk, where he was elected organist, with an annual salary of £100, and where he resided for the next nine years. During that time he began to entertain the idea of writing a general history of music. In 1760 he returned to London in good health, and with a young family; the eldest of whom, a girl of eight years of age, surprised the public by her attainments as a harpsichord player. In 1766 he produced, at Drury lane, a free English version and adaptation of J. J. Rousseau's operetta *Le Devin du Village*, under the title of *The Cunning Man*, which was favourably received. The university of Oxford conferred

[1] "Which," says Dr Johnson, "the critick ought to read for its elegance, the philosopher for its arguments, and the saint for its piety" (*Lives of English Poets*, vol. i. p. 303).

upon him, on 23d June 1769, the degrees of bachelor and doctor of music, on which occasion he presided at the performance of his exercise for these degrees. This consisted of an anthem, with an overture, solos, recitatives, and choruses, accompanied by instruments, besides a vocal anthem in eight parts, which was not performed. His friend, C. P. E. Bach, requested a copy of this exercise, and had it performed in St Catharine's Church at Hamburg, under his own direction, in 1773. It was repeatedly performed at Oxford, "after it had fufilled its original destination," as Burney tells us (*Hist. of Music*, vol. iii. p. 329); and he apologizes as follows for saying so much about it:—"It is hoped that the reader will pardon this *egotism*, which has been extorted from me by occasional and sinister assertions, 'that I neither liked nor had studied church music.'" (*Ibid*). In 1769 he published *An Essay towards a History of Comets*. Amidst his various professional avocations, Burney never lost sight of his favourite object,—his *History of Music*,—and therefore resolved to travel abroad for the purpose of collecting materials that could not be found in Great Britain. Accordingly, he left London in June 1770, furnished with numerous letters of introduction, and proceeded to Paris, and thence to Genevá, Turin, and the principal cities of Italy. The results of his observations he published in *The Present State of Music in France and Italy* (1 vol. 8vo, London, 1771). Dr Johnson thought so well of this work, that, alluding to his own *Journey to the Western Islands of Scotland*, he said, "I had that clever dog Burney's Musical Tour in my eye." In July 1772 Burney again visited the Continent, to collect further materials, and, after his return to London, published his tour under the title of *The Present State of Music in Germany, the Netherlands, and United Provinces* (2 vols. 8vo, London, 1773). In 1773 he was chosen a Fellow of the Royal Society of London. In 1776 appeared the first volume (in 4to) of his long-projected *History of Music*; in 1782 the second volume; and in 1789 the third and fourth. Though severely criticised by Forkel in Germany and by the Spanish ex-Jesuit, Requeno, who, in his Italian work *Saggj sul Ristabilimento dell' Arte Armonica de' Greci e Romani Cantori*, Parma, 1798 (2 vols. 8vo), attacks Burney's account of the ancient Greek music, and calls him *lo scompigliato Burney*, the *History of Music* was generally recognized as possessing great merit. The least satisfactory volume is the fourth, the treatment of Handel and Bach being quite inadequate. Burney's first Tour was translated into German by Ebeling, and printed at Hamburg in 1772; and his second Tour, translated into German by Bode, was published at Hamburg in 1773. A Dutch translation of his second Tour, with notes by J. W. Lustig, organist at Groningen, was published there in 1786 The Dissertation on the Music of the Ancients, in the first volume of Burney's *History*, was translated into German by J. J. Eschenburg, and printed at Leipsic, 1781. Burney derived much aid from the first two volumes of Padre Martini's very learned *Storia della Musica*, Bologna, 1757–1770. One cannot but admire his persevering industry, and his sacrifices of time, money and personal comfort, in collecting and preparing materials for his *History*; and few will be disposed to condemn severely errors and oversights in a work of such extent and difficulty. In 1779 he wrote for the Royal Society an account of the infant Crotch, whose remarkable musical talent excited so much attention at that time In 1784 he published, with an Italian title-page, the music annually performed in the Pope's chapel at Rome during Passion Week. In 1785 he published, for the benefit of the Musical Fund, an account of the first commemoration of Handel in Westminster Abbey in the preceding year, with an excellent life of Handel. In 1796 he published *Memoirs and Letters of Metastasio*, 3 vols. 8vo. Towards the close of his life, Burney contributed to the Rev. Dr Rees's *Cyclopædia* all the musical articles not belonging to the department of Natural Philosophy and Mathematics. For these articles he received £1000, which seems a remarkable remuneration, considering that most of his materials were merely transcribed from his own *History of Music*. In 1789, through the treasury influence of his friend Edmund Burke, he was appointed organist to the chapel of Chelsea Hospital, and he resided in the hospital for the remainder of his life. He was made a member of the Institute of France, and nominated a correspondent in the class of the Fine Arts, in the year 1810. He died at Chelsea College on the 12th of April 1814, and was interred in the burying-ground of the college on the 20th of the same month.

Burney had a wide circle of acquaintance among the distinguished artists and literary men of his day. At one time he thought of writing a life of his friend Dr Samuel Johnson; but he retired before the crowd of biographers who rushed into that field. His character in private as well as public life appears to have been very amiable and exemplary. Dr Burney's eldest son, James, was a distinguished officer in the royal navy, and died a rear-admiral in 1821. He published several works of merit. A notice of his second son, the Rev. Charles Burney, D.D., an eminent Greek scholar, will be found below, and of his second daughter Frances (Madame D'Arblay) under the heading D'Arblay. The *Diary and Letters* of Madame D'Arblay contain many minute and interesting particulars of her father's public and private life, and of his friends and contemporaries. A life of her father, by Madame D'Arblay, appeared in 1832.

Besides the operatic music above mentioned, Burney's known compositions consist of—1. *Six Sonatas for the harpsichord*; 2. *Two Sonatas for the harp or piano, with accompaniments for violin and violoncello*; 3. *Sonatas for two violins and a bass: two sets*; 4. *Six Lessons for the harpsichord*; 5. *Six Duets for two German flutes*; 6. *Three Concertos for the harpsichord*; 7. *Six concert pieces with an introduction and fugue for the organ*; 8. *Six Concertos for the violin, &c., in eight parts*; 9. *Two Sonatas for pianoforte, violin, and violoncello*; 10. *A Cantata, &c.*; 11. *Anthems, &c.*; 12. *XII. Canzonetti a due voci in Canone, poesia dell' Abate Metastasio.*

BURNEY, Charles (1757–1817), son of the preceding, an eminent classical scholar, was born at Lynn, in Norfolk, in 1757. At the age of eleven he was sent to the Charterhouse in London, whence he removed to Caius College, Cambridge. He quitted the university without taking his degree; but in 1791 he received the diploma of LL.D. from Aberdeen, and in 1808 that of D.D. from Cambridge. In 1783 he married the daughter of Dr Rose, the translator of Sallust, and continued for some time to assist his father-in-law in the management of his academy. He contributed at this time many articles to the *Monthly Review*, and afterwards edited for two or three years the *London Magazine*. Some of his contributions to the first of these periodicals gained him much credit not only among English but among Continental scholars. In the course of time he realized a handsome fortune, great part of which he expended in the formation of his splendid library. The manuscripts and rare books collected by him were considered so valuable that at his death, which happened in 1817, they were purchased by the nation and deposited in the British Museum.

BURNEY, Frances. See D'Arblay.

BURNLEY, a manufacturing town and municipal and parliamentary borough of England, 22 miles N. of Manchester, in a valley on the River Burn, from which it derives it name, and in the immediate vicinity of the Leeds and Liverpool canal. Its streets are well paved, and there is an abundant supply of water. Among its buildings of note are the frequently restored church of St Peter's; a market hall, erected in 1866; and a literary institution

and exchange. It also possesses a Church of England institute, with a considerable library, a free grammar school, and several charities. Its staple manufacture is cotton, which in 1872 gave employment to 7972 men and 8267 women of twenty years of age and upwards. Worsted, which was formerly the chief article, is still manufactured to a considerable extent. Calico-printing, machine-making, brewing, tanning, and several other important industries are carried on in the town; and in the neighbourhood there are iron mines and stone quarries, which gave employment in 1872 to 1376 and 360 workmen respectively. From the number of Roman remains found at various times on the spot, Burnley seems to be the site of some Roman station; and it has also been suggested that it may coincide with Brunnanburh, the famous battle-field of the Saxons. There are but few facts of importance in its history. During the cotton famine it suffered severely, and the operatives were employed in an extensive system of improvements, to which the present satisfactory condition of the town is mainly due. In 1861 it was incorporated by royal charter, the government being placed in the hands of a mayor, eight aldermen, and twenty-four councillors; and in 1867 it was entrusted with the right of electing one member of Parliament. The population of the parliamentary borough in 1871 was 44,320 persons, of whom 21,368 were males and 22,952 females; the inhabited houses were 8804, and the registered electors 5628.

BURNOUF, EUGÈNE (1801–1852), an Oriental scholar, was born at Paris in 1801. He was educated for the legal profession, but soon after taking his degree began to devote himself entirely to the study of Oriental languages. In 1826 he published an *Essai sur le Pali*, and in the following year *Observations Grammaticales sur quelques Passages de l'Essai sur le Pali*. The next great work he undertook was the deciphering of the Zend manuscripts brought to France by Anquetil du Perron. By his labours a knowledge of the Persian language and religion was first brought into the scientific world of Europe. He caused the *Vendidad Sadé* to be lithographed with the utmost care, and published it in folio, 1829–43. The contributions he made to Oriental literature in the *Journal Asiatique* were numerous and important. From 1833 to 1835 he published his *Commentaries sur le Yaçna, l'un des livres liturgiques des Perses*; in 1840 he began the publication of the Sanskrit text and French translation of the *Bhagavata Purana*, which was completed in three folio volumes. His last works were *Introduction à l'Histoire du Bouddhisme Indien*, and a translation of *Le Lotus de la Bonne Loi*. The latter work was passing through the press when the author died on the 28th May 1852 He was a member of the *Académie des Inscriptions*, and from 1832 had held the post of professor of Sanskrit in the Collége de France.

BURNOUF, JEAN LOUIS (1775–1844), the father of Eugène Burnouf, was born in 1775. During the intervals of leisure left him by his commercial employment he prosecuted his studies in classical literature, and in 1808 was appointed assistant-professor at the Lycée Charlemagne. He soon afterwards obtained the chair of rhetoric at the Lycée Imperial, which he held till 1826, when he was made the inspector of the Academy. In 1817 he had been appointed professor of Latin eloquence at the Collége de France, and from 1811 to 1822 he acted as president of the École Normale. In 1830 Burnouf was named inspector-general of studies, and on his resignation of this post in 1836 was made librarian of the university. He died in 1844. His most important work was the *Méthode pour étudier la Langue Grecque*, 1814, which marks an epoch in the study of Greek in France. He also published a valuable edition of Sallust and some excellent translations of Tacitus, and of parts of Sallust and Cicero.

BURNS, ROBERT (1759–1796). In a company of German critics who were weighing the claims and estimating the rank of the poets, their contemporaries, the leader of their chorus, the genial humorist, Jean Paul Richter, is said to have hushed his audience when the name of Goethe was introduced, exclaiming—"We are not to sit in judgment on that sacred head." Scotsmen are apt to attach the same half-superstitious reverence to the name which is, more than any other, that of Scotland condensed in a personality, the representative of what is noblest and also of much that is erring in their race.

Robert Burns was born on the 25th of January 1759, in a cottage about two miles from Ayr, the eldest son of a small farmer, William Burness, of Kincardineshire stock, who wrought hard, practised integrity, wished to bring up his children in the fear of God, but had to fight all his days against the winds and tides of adversity. "The poet," says Mr Carlyle, his best biographer, "was fortunate in his father—a man of thoughtful intense character, as the best of our peasants are, valuing knowledge, possessing some and open-minded for more, of keen insight and devout heart, friendly and fearless: a fully unfolded man seldom found in any rank in society, and worth descending far in society to seek. . . . Had he been ever so little richer, the whole might have issued otherwise. But poverty sunk the whole family even below the reach of our cheap school system, and Burns remained a hard-worked plough-boy."

Through a series of migrations from one unfortunate farm to another; from Alloway (where he was taught to read), to Mt. Oliphant, and then (1777) to Lochlea in Tarbolton (where he learnt the rudiments of geometry), the poet remained in the same condition of straitened circumstances. At the age of thirteen he thrashed the corn with his own hands, at fifteen he was the principal labourer. The family kept no servant, and for several years butchers' meat was a thing unknown in the house. "This kind of life," he writes, "the cheerless gloom of a hermit and the unceasing toil of a galley-slave, brought me to my sixteenth year." His naturally robust frame was overtasked, and his nervous constitution received a fatal strain. His shoulders were bowed, he became liable to headaches, palpitations, and fits of depressing melancholy. From these hard tasks and his fiery temperament, craving in vain for sympathy in a frigid air grew the strong temptations on which Burns was largely wrecked,—the thirst for stimulants and the revolt against restraint which soon made headway and passed all bars. In the earlier portions of his career, a buoyant humour bore him up; and amid thick-coming shapes of ill he bated no jot of heart or hope. He was cheered by vague stirrings of ambition, which he pathetically compares to the "blind groping of Homer's Cyclops round the walls of his cave." Sent to school at Kirkoswald, he became, for his scant leisure, a great reader—eating at meal-times with a spoon in one hand and a book in the other,—and carrying a few small volumes in his pocket to study in spare moments in the fields. "The collection of songs," he tells us, "was my *vade mecum*. I pored over them driving my cart or walking to labour, song by song, verse by verse, carefully noting the true, tender, sublime, or fustian." He lingered over the ballads in his cold room by night; by day, whilst whistling at the plough, he invented new forms and was inspired by fresh ideas, "gathering round him the memories and the traditions of his country till they became a mantle and a crown." It was among the furrows of his father's fields that he was inspired with the perpetually quoted wish—

> "That I for poor auld Scotland's sake
> Some useful plan or book could make,
> Or sing a sang at least."

An equally striking illustration of the same feeling is to be found in his summer Sunday's ramble to the Leglen

wood,—the fabled haunt of Wallace,—which the poet confesses to have visited "with as much devout enthusiasm as ever pilgrim did the shrine of Loretto." In another reference to the same period he refers to the intense susceptibility to the homeliest aspects of Nature which throughout characterized his genius. "Scarcely any object gave me more—I do not know if I should call it pleasure—but something which exalts and enraptures me—than to walk in the sheltered side of a wood or high plantation in a cloudy winter day and hear the stormy wind howling among the trees and raving over the plain. I listened to the birds, and frequently turned out of my path lest I should disturb their little songs or frighten them to another station." Auroral visions were gilding his horizon as he walked in glory, if not in joy, "behind his plough upon the mountain side;" but the swarm of his many-coloured fancies was again made grey by the *atra cura* of unsuccessful toils.

Burns had written his first verses of note, "Behind yon hills where Stinchar (afterwards Lugar) flows," when in 1781 he went to Irvine to learn the trade of a flax-dresser. "It was," he says, "an unlucky affair. As we were giving a welcome carousal to the New Year, the shop took fire and burned to ashes; and I was left, like a true poet, without a sixpence." His own heart, too, had unfortunately taken fire. He was poring over mathematics till, in his own phraseology,—still affected in its prose by the classical pedantries caught from Pope by Ramsay,—"the sun entered Virgo, when a charming *fillette*, who lived next door, overset my trigonometry, and set me off at a tangent from the scene of my studies." We need not detail the story, nor the incessant repetitions of it, which marked and sometimes marred his career. The poet was jilted, went through the usual despairs, and resorted to the not unusual sources of consolation. He had found that he was "no enemy to social life," and his mates had discovered that he was the best of boon companions in the lyric feasts, where his eloquence shed a lustre over wild ways of life, and where he was beginning to be distinguished as a champion of the New Lights and a satirist of the Calvinism whose waters he found like those of Marah.

In Robert's 25th year his father died, full of sorrows and apprehensions for the gifted son who wrote for his tomb, in Alloway kirkyard, the fine epitaph ending with the characteristic line—

"For even his failings leaned to virtue's side.'

For some time longer the poet, with his brother Gilbert, lingered at Lochlea, reading agricultural books, miscalculating crops, attending markets, and in a mood of reformation resolving, "in spite of the world, the flesh, and the devil, to be a wise man." Affairs, however, went no better with the family; and in 1784 they migrated to Mossgiel, where he lived and wrought, during four years, for a return scarce equal to the wage of the commonest labourer in our day. Meanwhile he had become intimate with his future wife, Jean Armour; but the father, a master mason, discountenanced the match, and the girl being disposed to "sigh as a lover," as a daughter to obey, Burns, in 1786, gave up his suit, resolved to seek refuge in exile, and having accepted a situation as book-keeper to a slave estate in Jamaica, had taken his passage in a ship for the West Indies. His old associations seemed to be breaking up, men and fortune scowled, and "hungry ruin had him in the wind," when he wrote the lines ending—

"Adieu, my native banks of Ayr,"

and addressed to the most famous of the loves, in which he was as prolific as Catullus or Tibullus, the proposal—

"Will ye go to the Indies, my Mary.

He was withheld from his project and, happily or unhappily, the current of his life was turned by the success of his first volume, which was published at Kilmarnock in June 1786. It contained some of his most justly celebrated poems, the results of his scanty leisure at Lochlea and Mossgiel; among others "The Twa dogs,"—a graphic idealization of Æsop,—"The Author's Prayer," the "Address to the Deil," "The Vision" and "The Dream," "Halloween," "The Cottar's Saturday Night," the lines "To a Mouse" and "To a Daisy," "Scotch Drink," "Man was made to Mourn," the "Epistle to Davie," and some of his most popular songs. This epitome of a genius so marvellous and so varied took his audience by storm. "The country murmured of him from sea to sea." "With his poems," says Robert Heron, "old and young, grave and gay, learned and ignorant, were alike transported. I was at that time resident in Galloway, and I can well remember how even plough-boys and maid-servants would have gladly bestowed the wages they earned the most hardly, and which they wanted to purchase necessary clothing, if they might but procure the works of Burns. This first edition only brought the author £20 direct return, but it introduced him to the *literati* of Edinburgh, whither he was invited, and where he was welcomed, feasted, admired, and patronized. He appeared as a portent among the scholars of the northern capital and its university, and manifested, according to Mr Lockhart, "in the whole strain of his bearing, his belief that in the society of the most eminent men of his nation he was where he was entitled to be, hardly deigning to flatter them by exhibiting a symptom of being flattered."

Sir Walter Scott bears a similar testimony to the dignified simplicity and almost exaggerated independence of the poet, during this *annus mirabilis* of his success. "As for Burns, *Virgilium vidi tantum*, I was a lad of fifteen when he came to Edinburgh, but had sense enough to be interested in his poetry, and would have given the world to know him. I saw him one day with several gentlemen of literary reputation, among whom I remember the celebrated Dugald Stewart. Of course we youngsters sat silent, looked, and listened. . . . I remember . . . his shedding tears over a print representing a soldier lying dead in the snow, his dog sitting in misery on one side, on the other his widow with a child in her arms. His person was robust, his manners rustic, not clownish. . . . His countenance was more massive than it looks in any of the portraits. There was a strong expression of shrewdness in his lineaments; the eye alone indicated the poetic character and temperament. It was large and of a dark cast, and literally glowed when he spoke with feeling or interest. I never saw such another eye in a human head. His conversation expressed perfect self-confidence, without the least intrusive forwardness. I thought his acquaintance with English poetry was rather limited; and having twenty times the abilities of Allan Ramsay and of Ferguson he talked of them with too much humility as his models. He was much caressed in Edinburgh, but the efforts made for his relief were extremely trifling." *Laudatur et alget.* Burns went from those meetings, where he had been posing professors (no hard task), and turning the heads of duchesses, to share a bed in the garret of a writer's apprentice,—they paid together 3s. a week for the room. It was in the house of Mr Carfrae, Baxter's Close, Lawnmarket, "first scale stair on the left hand in going down, first door in the stair." During Burns's life it was reserved for William Pitt to recognize his place as a great poet, the more cautious critics of the North were satisfied to endorse him as a rustic prodigy, and brought upon themselves a share of his satire. Some of the friendships contracted during this period—as for Lord Glencairn and Mrs Dunlop—are among the most pleasing and permanent in literature; for genuine kind-

ness was never wasted on one who, whatever his faults, has never been accused of ingratitude. But in the bard's city life there was an unnatural element. He stooped to beg for neither smiles nor favour, but the gnarled country oak is cut up into cabinets in artificial prose and verse. In the letters to Mr Graham, the prologue to Mr Wood, and the epistles to Clarinda, he is dancing minuets with hob-nailed shoes. When, in 1787, the second edition of the *Poems* came out, the proceeds of their sale realized for the author £400. On the strength of this sum he gave himself two long rambles, full of poetic material—one through the border towns into England as far as Newcastle, returning by Dumfries to Mauchline, and another a grand tour through the East Highlands, as far as Inverness, returning by Edinburgh, and so home to Ayrshire.

In 1788 Burns took a new farm at Ellisland on the Nith, settled there, married, lost his little money, and wrote, among other pieces, "Auld Lang Syne" and "Tam O' Shanter." In 1789 he obtained, through the good office of Mr Graham of Fintry, an appointment as excise-officer of the district, worth £50 per annum. In 1791 he removed to a similar post at Dumfries worth £70. In the course of the following year he was asked to edit and supply the *Melodies of Scotland with Symphonies and Accompaniments for the Pianoforte and Violin: the poetry by Robert Burns.* To this work he contributed about one hundred songs, the best of which are now ringing in the ear of every Scotchman from New Zealand to San Francisco. For these, original and adapted, he received a shawl for his wife, a picture by David Allan representing the "Cottar's Saturday Night," and £5! The poet wrote an indignant letter and never afterwards composed for money. Unfortunately the "Rock of Independence" to which he had proudly retired was but a castle of air, over which the meteors of French political enthusiasm cast a lurid gleam. In the last years of his life, exiled from polite society on account of his revolutionary opinions, he became sourer in temper and plunged more deeply into the dissipations of the lower ranks, among whom he found his only companionship and sole, though shallow, sympathy. To have Jacobin tendencies, to rejoice at the downfall of the Bastille, was regarded as the sign of an abandoned character, as it was twelve years ago in Scotland to embrace the cause of the Northern States in the American War.

Burns began to feel himself prematurely old. Walking with a friend who proposed to him to join a county ball, he shook his head, saying "that's all over now," and adding a verse of Lady Grissel Baillie's ballad—

> "O were we young as we ance hae been,
> We sud hae been galloping down on yon green,
> And linking it ower the lily-white lea,
> But were na my heart light I wad dee."

His hand shook; his pulse and appetite failed; his spirits sunk into a uniform gloom. In April 1796 he wrote—"I fear it will be some time before I tune my lyre again. By Babel's streams I have sat and wept. I have only known existence by the pressure of sickness and counted time by the repercussions of pain. I close my eyes in misery and open them without hope. I look on the vernal day and say with poor Ferguson—

> "Say wherefore has an all-indulgent heaven
> Life to the comfortless and wretched given."

On the 4th of July he was seen to be dying. On the 12th he wrote to his cousin for the loan of £10 to save him from passing his last days in jail. On the 21st he was no more. On the 25th, when his last son came into the world, he was buried with local honours, the volunteers of the company to which he belonged firing three volleys over his grave.

It has been said that "Lowland Scotland as a distinct nationality came in with two warriors and went out with two bards. It came in with William Wallace and Robert Bruce and went out with Robert Burns and Walter Scott. The first two made the history, the last two told the story and sung the song." But what in the minstrel's lay was mainly a requiem was in the people's poet also a prophecy. The position of Burns in the progress of our literature may be shortly defined; he was a link between two eras, like Chaucer, the last of the old and the first of the new—the inheritor of the traditions and the music of the past, in some respects the herald of the future.

The volumes of our lyrist owe part of their popularity to the fact of their being an epitome of melodies, moods, and memories that had belonged for centuries to the national life, the best inspirations of which have passed into them. But in gathering from his ancestors Burns has exalted their work by asserting a new dignity for their simplest themes. He is the heir of Barbour, distilling the spirit of the old poet's epic into a battle chant, and of Dunbar, reproducing the various humours of a half-sceptical, half-religious philosophy of life. He is the pupil of Ramsay, but he leaves his master, to make a social protest and to lead a literary revolt. The *Gentle Shepherd*, still largely a court pastoral, in which "a man 's a man" if born a gentleman, may be contrasted with the "Jolly Beggars"—the one is like a minuet of the ladies of Versailles on the sward of the Swiss village near the Trianon, the other like the march of the mænads with Theroigne de Mericourt. Ramsay adds to the rough tunes and words of the ballads the refinement of the wits who in the "Easy" and "Johnstone" clubs talked over their cups of Prior and Pope, Addison and Gay. Burns inspires them with a fervour that thrills the most wooden of his race. We may clench the contrast by a representative example. This is from Ramsay's version of perhaps the best known of our songs,—

> "Methinks around us on each bough
> A thousand Cupids play;
> Whilst through the groves I walk with you,
> Each object makes me gay.
> Since your return—the sun and moon
> With brighter beams do shine,
> Streams murmur soft notes while they run
> As they did lang syne."

Compare the verses in Burns—

> "We twa hae run about the braes
> And pou't the gowans fine;
> But we've wandered mony a weary foot
> Sin auld lang syne.
> We twa hae paidl'd in the burn,
> Frae morning sun till dine:
> But seas between us braid hae roar'd
> Sin auld lang syne."

Burns as a poet of the inanimate world doubtless derived hints from Thomson (*i.e.*, the poet, not his correspondent), but in his power of tuning its manifestations to the moods of the mind he is more properly ranked as a forerunner of Wordsworth. He never follows the fashions of his century, except in his failures—in his efforts at set panegyric or fine letter-writing. His highest work knows nothing of "Damon" or "Musidora." He leaves the atmosphere of drawing-rooms for the ingle or the ale-house or the mountain breeze.

The affectations of his style are insignificant and rare. His prevailing characteristic is an absolute sincerity. A love for the lower forms of social life was his besetting sin; Nature was his healing power. Burns compares himself to an Æolian harp, strung to every wind of heaven. His genius flows over all living and lifeless things with a sympathy that finds nothing mean or insignificant. An uprooted daisy becomes in his pages an enduring emblem of the fate of artless maid and simple bard. He disturbs

a mouse's nest and finds in the "tim'rous beastie" a fellow-mortal doomed like himself to "thole the winter's sleety dribble," and draws his oft-repeated moral. He walks abroad and, in a verse that glints with the light of its own rising sun before the fierce sarcasm of the "Holy Fair," describes the melodies of a "simmer Sunday morn." He loiters by Afton Water and "murmurs by the running brook a music sweeter than its own." He stands by a roofless tower, where "the howlet mourns in her dewy bower," and "sets the wild echoes flying," and adds to a perfect picture of the scene his famous vision of "Libertie." In a single stanza he concentrates the sentiment of many Night Thoughts—

> "The pale moon is setting beyond the white wave,
> And Time is setting wi' me, O."

For other examples of the same graphic power we may refer to the course of his stream—

> "Whiles ow'r a linn the burnie plays
> As through the glen it wimpled," &c.,

or to the "Birks of Aberfeldy" or the "spate" in the dialogue of the "Brigs of Ayr." The poet is as much at home in the presence of this flood as by his "trottin' burn's meander." Familiar with all the seasons, he represents the phases of a northern winter with a frequency characteristic of his clime and of his fortunes; her tempests become anthems in his verse, and the sounding woods "raise his thoughts to Him that walketh on the wings of the wind;" full of pity for the shelterless poor, the "ourie cattle," the "silly sheep," and the "helpless birds," he yet reflects that the bitter blast is not "so unkind as man's ingratitude." This constant tendency to ascend above the fair or wild features of outward things, or to penetrate beneath them, to make them symbols, to endow them with a voice to speak for humanity, distinguishes Burns as a descriptive poet from the rest of his countrymen. As a painter he is rivalled by Dunbar and James I., more rarely by Thomson and Ramsay. The "lilt" of Tannahill's finest verse is even more charming. But these writers rest in their art; their main care is for their own genius. The same is true in a minor degree of some of his great English successors. Keats has a palette of richer colours, but he seldom condescends to "human nature's daily food." Shelley floats in a thin air to stars and mountain tops, and vanishes from our gaze like his skylark. Byron, in the midst of his revolutionary fervour, never forgets that he himself belongs to the "caste of Vere de Vere." Wordsworth's placid affection and magnanimity stretch beyond mankind, and, as in "Hart-leap-well" and the "Cuckoo," extend to bird and beast; he moralizes grandly on the vicissitudes of common life, but he does not enter into, because by right of superior virtue he places himself above them. "From the Lyrical Ballads," it has been said, "it does not appear that men eat or drink, marry or are given in marriage." We revere the monitor who, consciously good and great, gives us the dry light of truth, but we love the bard, *nostræ deliciæ*, who is all fire—fire from heaven and Ayrshire earth mingling in the outburst of passion and of power, which is his poetry and the inheritance of his race. He had certainly neither culture nor philosophy enough to have written the "Ode on the Recollections of Childhood," but to appreciate that ode requires an education. The sympathies of Burns, as broad as Wordsworth's, are more intense; in turning his pages we feel ourselves more decidedly in the presence of one who joys with those who rejoice and mourns with those who mourn. He is never shallow, ever plain, and the expression of his feeling is so terse that it is always memorable. Of the people he speaks more directly for the people than any of our more considerable poets. Chaucer has a perfect hold of the homeliest phases of life, but he wants the lyric element, and the charm of his language has largely faded from untutored ears. Shakespeare, indeed, has at once a loftier vision and a wider grasp; for he sings of "Thebes and Pelops line," of Agincourt and Philippi, as of Falstaff, and Smug the joiner, and the "meanest flower that blows." But not even Shakespeare has put more thought into poetry which the most prosaic must appreciate than Burns has done. The latter moves in a narrower sphere and wants the strictly dramatic faculty, but its place is partly supplied by the vividness of his narrative. His realization of incident and character is manifested in the sketches in which the manners and prevailing fancies of his countrymen are immortalized in connection with local scenery. Among those almost every variety of disposition finds its favourite. The quiet households of the kingdom have received a sort of apotheosis in the "Cottar's Saturday Night." It has been objected that the subject does not afford scope for the more daring forms of the author's genius; but had he written no other poem, this heartful rendering of a good week's close in a God-fearing home, sincerely devout, and yet relieved from all suspicion of sermonizing by its humorous touches, would have secured a permanent place in our literature. It transcends Thomson and Beattie at their best, and will smell sweet like the actions of the just for generations to come. Lovers of rustic festivity may agree with Professor Craik in holding that the poet's greatest performance is his narrative of "Halloween," which for easy vigour, fulness of rollicking life, blended truth and fancy, is unsurpassed in its kind. Campbell, Wilson, Hazlitt, Montgomery, Burns himself, and the majority of his critics, have recorded their preference for "Tam 'O Shanter," where the weird superstitious element that has played so great a part in the imaginative work of this part of our island is brought more prominently forward. Few passages of description are finer than that of the roaring Doon and Alloway Kirk glimmering through the groaning trees; but the unique excellence of the piece consists in its variety, and a perfectly original combination of the terrible and the ludicrous. Like Goethe's *Walpurgis Nacht*, brought into closer contact with real life, it stretches from the drunken humours of Christopher Sly to a world of fantasies almost as brilliant as those of the *Midsummer Night's Dream*, half solemnized by the severer atmosphere of a sterner clime. The contrast between the lines "Kings may be blest," &c., and those which follow, beginning "But pleasures are like poppies spread," is typical of the perpetual antithesis of the author's thought and life, in which, at the back of every revelry, he sees the shadow of a warning hand, and reads on the wall the writing, *Omnia mutantur*. With equal or greater confidence other judges have pronounced Burns's masterpiece to be "The Jolly Beggars." Certainly no other single production so illustrates his power of exalting what is insignificant, glorifying what is mean, and elevating the lowest details by the force of his genius. "The form of the piece," says Mr Carlyle, "is a mere cantata, the theme the half-drunken snatches of a joyous band of vagabonds, while the grey leaves are floating on the gusts of the wind in the autumn of the year. But the whole is compacted, refined, and poured forth in one flood of liquid harmony. It is light, airy, and soft of movement, yet sharp and precise in its details; every face is a portrait, and the whole a group in clear photography. The blanket of the night is drawn aside; in full ruddy gleaming light these rough tatterdemalions are seen at their boisterous revel wringing from Fate another hour of wassail and good cheer." Over the whole is flung a half-humorous, half-savage satire—aimed, like a two-edged sword, at the laws and the law-breakers, in the acme of which the graceless crew are raised above the level of ordinary gipsies, footpads,

and rogues, and are made to sit "on the hills like gods together, careless of mankind," and to launch their Titan thunders of rebellion against the world.

> "A fig for those by law protected;
> Liberty 's a glorious feast;
> Courts for cowards were erected,
> Churches built to please the priest."

A similar mixture of drollery and defiance appears in the justly-celebrated "Address to the Deil," which, mainly whimsical, is relieved by touches of pathos curiously quaint. "The effect of contrast," it has been observed, "was never more happily displayed than in the conception of such a being straying in lonely places and loitering among trees, or in the familiarity with which the poet lectures so awful a personage,"—we may add, than in the inimitable outbreak, anticipatory of Professor Maurice, at the close—

> "O would you tak a thought an' men'."

Mr Carlyle, in reference to this passage, cannot resist the suggestion of a parallel from Sterne. "He is the father of curses and lies, said Dr Slop, and is cursed and damned already. I am sorry for it, quoth my Uncle Toby."

Burns fared ill at the hands of those who were not sorry for it, and who repeated with glib complacency every terrible belief of the system in which they had been trained. The most scathing of his *Satires*, under which head fall many of his minor and frequent passages in his major pieces, are directed against the false pride of birth, and what he conceived to be the false pretences of religion. The apologue of "Death and Dr Hornbook," "The Ordination," the song "No churchman am I for to rail and to write," the "Address to the Unco Guid," "Holy Willie," and above all "The Holy Fair," with its savage caricature of an ignorant ranter of the time called Moodie, and others of like stamp, not unnaturally provoked offence. As regards the poet's attitude towards some phases of Calvinism prevalent during his life, it has to be remarked that from the days of Dunbar till now there has been a degree of antagonism between Scotch verse and the more rigid forms of Scotch theology.

It must be admitted that in protesting against hypocrisy he has occasionally been led beyond the limits prescribed by good taste. He is at times abusive of those who differ from him. This, with other offences against decorum, which here and there disfigure his pages, can only be condoned by an appeal to the general tone of his writing, which is reverential. Burns had a firm faith in a Supreme Being, not as a vague mysterious Power, but as the Arbiter of human life. Amid the vicissitudes of his career he responds to the cottar's summons, "Let us worship God."

> "An atheist's laugh 's a poor exchange
> For Deity offended"

is the moral of all his verse, which treats seriously of religious matters. His prayers in rhyme give him a high place among secular Psalmists.

Like Chaucer, Burns was a great moralist, though a rough one. In the moments of his most intense revolt against conventional prejudice and sanctimonious affectation, he is faithful to the great laws which underlie change, loyal in his veneration for the cardinal virtues—Truth, Justice, and Charity,—and consistent in the warnings, to which his experience gives an unhappy force, against transgressions of Temperance. In the "Epistle to a Young Friend," the shrewdest advice is blended with exhortations appealing to the highest motive, that which transcends the calculation of consequences, and bids us walk in the straight path from the feeling of personal honour, and "for the glorious privilege of being independent." Burns, like Dante, "loved well because he hated, hated wickedness that hinders loving," and this feeling, as in the lines—"Dweller in yon dungeon dark," sometimes breaks bounds; but his calmer moods are better represented by the well-known passages in the "Epistle to Davie," in which he preaches acquiescence in our lot, and a cheerful acceptance of our duties in the sphere where we are placed. This *philosophie douce*, never better sung by Horace, is the prevailing refrain of our author's *Songs*. On these there are few words to add to the acclaim of a century. They have passed into the air we breathe; they are so real that they seem things rather than words, or, nearer still, living beings. They have taken all hearts, because they are the breath of his own; not polished cadences, but utterances as direct as laughter or tears. Since Sappho loved and sung, there has been no such national lyrist as Burns. Fine ballads, mostly anonymous, existed in Scotland previous to his time; and shortly before a few authors had produced a few songs equal to some of his best. Such are Alexander Ross's "Wooed and married," Lowe's "Mary's Dream," "Auld Robin Gray," "The Land o' the Leal," and the two versions of "The Flowers o' the Forest." From these and many of the older pieces in Ramsay's collection, Burns admits to have derived copious suggestions and impulses. He fed on the past literature of his country as Chaucer on the old fields of English thought, and—

> "Still the elements o' sang,
> In formless jumble, right and wrang,
> Went floating in his brain."

But he gave more than he received; he brought forth an hundred-fold; he summed up the stray material of the past, and added so much of his own that one of the most conspicuous features of his lyrical genius is its variety in new paths. Between the first of war songs, composed in a storm on a moor, and the pathos of "Mary in Heaven," he has made every chord in our northern life to vibrate. The distance from "Duncan Gray" to "Auld Lang Syne" is nearly as great as that from Falstaff to Ariel. There is the vehemence of battle, the wail of woe, the march of veterans "red-wat-shod," the smiles of meeting, the tears of parting friends, the gurgle of brown burns, the roar of the wind through pines, the rustle of barley rigs, the thunder on the hill—all Scotland is in his verse. Let who will make her laws, Burns has made the songs, which her emigrants recall "by the long wash of Australasian seas," in which maidens are wooed, by which mothers lull their infants, which return "through open casements unto dying ears"—they are the links, the watchwords, the masonic symbols of our race.

In his "Vision" the poet imagines his Muse (probably as real to him as to Homer) descending to address her votary beside the plough. After paying through her lips a generous tribute to his predecessors, he draws, as usual, a lesson from his own career, "by passion driven." The goddess counsels him to "preserve the dignity of man" and "trust the universal plan," and leaving a wreath of green holly to deck his brows, passes "in light away."

The poet passed away in darkness, but his name will never disappear from our literature. He stands before us as a feature of Nature; and the fact that he cannot be moved from the hearts of his countrymen, that they recognize and respect a man who has refused to mutilate human nature, and who at once celebrates and strives to harmonize its ethnical and Christian elements, marks a gulf still fixed between Scotland and the Spain with which Mr Buckle has associated it. "The generous verse of Burns," says Dr Craik, "springs out of the iron-bound Calvinism of the land like flowing water from Horeb's rock."

The first edition of Burns's *Poems* was published at Kilmarnock in 1 vol. 8vo, in 1786; the second edition was published in Edinburgh in 1787 (2 vols. 8vo); the third edition appeared at Dumfries in

1793. After the poet's death Dr Currie of Liverpool issued a collected edition of his works, with a Life, for the benefit of his widow and family (4 vols. 8vo, Lond. 1800). This included letters as well as poems, but was far from being complete. The edition of Allan Cunningham (8 vols. 8vo. Lond. 1834) contains a large number of pieces that are not to be found in Currie's edition. *The Life and Works of Burns*, by Dr Robert Chambers (Edin. 1851–2), has the distinctive feature that the poems are arranged in chronological order, and interwoven with the narrative of the poet's life, which is, perhaps, the fullest and most precise in its details that has appeared. The *Kilmarnock Popular Edition* (2 vols. Kilmarnock, 1871) possesses special interest from the fact that the first volume contains an exact reprint, with fac-simile title-page, of the original edition of 1786. It deserves notice that within a year of the publication of the first Edinburgh edition, two separate editions of the poems were issued in America, at New York and Philadelphia, 1788.

The *Life of Burns*, by J. Gibson Lockhart (1828), has passed through several editions. Among the numerous critical estimates of the poet the foremost place is given by universal consent to the essay of Carlyle, which first appeared in the *Edinburgh Review* (1828), and is reprinted among his miscellaneous essays. (J. N.)

BURNTISLAND, a parliamentary burgh and seaport of Scotland, in the county of Fife. It possesses a good pier, a dry dock, and a commodious harbour. Distilling and the herring-fishery are carried on, and a good deal of coal and pig-iron is exported. It is the northern station of the ferry across the Firth of Forth in connection with the North British Railway from Granton, from which it is about five miles distant. The burgh unites with Kirkcaldy, Kinghorn, and Dysart in sending one member to Parliament. The population in 1871 was 3422.

BURSLEM, a town of England, in the county of Staffordshire, 18 miles south of Macclesfield, and 150 miles from London. It stands on a gentle eminence near the Trent and Mersey canal, and is the principal town of the potteries' district. It contains a town-hall, erected in 1865, a market-house, a news-room, and a mechanics' institute; but its most interesting building is the Wedgwood Institute, founded in 1863 in honour of the great manufacturer, who was born in the town in 1730. It comprises a school of art, a free library, and a museum; and the exterior is richly and peculiarly ornamented, to show the progress of fictile art. The tower of the parish church is of some antiquity, though the building itself is of modern date. The town is mentioned in Domesday Book as *Barcardeslim*, and it appears at an early period as a seat of the pottery trade. Its prosperity was greatly increased in the end of the 18th century by the opening of the Grand Trunk canal. Population of township in 1872, 20,971.

BURTON, Robert (1576–1640), author of the *Anatomy of Melancholy*, was born at Lindley, Leicestershire, on the 8th February 1576. He attended the grammar schools of Nuneaton and Sutton Coldfields, and at the age of seventeen entered Brasenose College, Oxford. In 1599 he was elected student of Christ Church, and in 1614 took the degree of B.D. In 1616 he was presented to the vicarage of St Thomas, and in 1636 to the rectory of Segrave. He died on the 25th January 1639–40. *The Anatomy of Melancholy, what it is, with all the kinds, causes, symptoms, prognostics, and several cures of it: In three partitions, with their several sections, members, and sub-sections, philosophically, medicinally, historically opened and cut up: By Democritus Junior, with a satyrical preface conducing to the following discourse*, was published in 1621. Our information with regard to the strange author of this strange book is very scanty. Anthony Wood's account of him has often been quoted; it represents what must have been his contemporaries' opinion of him. A very curious anecdote is told of the method he adopted to dissipate the morbid melancholy which weighed upon him. He used to go to the bridge foot and hear the ribaldry of the bargemen, which rarely failed to throw him into a violent fit of laughter. His book is truly a marvellous production, and proves at least one thing, that the author was a thorough classical scholar. Indeed the work is a cento of quotations, and, like the *Intellectual System* of Cudworth, has served as a storehouse of learned material. Sterne is not the only one who has borrowed from the author of the *Anatomy*. The book itself is essentially unsystematic, but has a fine flavour of thorough-going ill-humour about it. This world was a dreary farce, and life was something to be laughed at. With a certain class of readers it has always been a favourite. Charles Lamb is a typical instance of a reader in Burton. The introductory poem has some curious analogies of style and thought to the *Allegro* and *Penseroso* of Milton.

BURTON-ON-TRENT, an English town, in the north-east part of the hundred of Offlow, and the eastern division of the county of Stafford. It is situated on the west bank of the River Trent, and is distant from Stafford 25 miles, from Derby 11 miles, and about 126 miles from London. The parish comprises over 9625 acres, and is divided into the townships of Burton-on-Trent, Burton Extra, Branston, Horninglow, and Stretton on the Staffordshire side of the river, and Stapenhill and Winshill on the Derbyshire side.

The history of the town may be said to begin with the erection of a church or monastery by the river side towards the close of the 9th century. But from that time we learn little concerning the place or its progress for about a hundred years. In 1002, the Burton abbey was founded by Wulfric, earl of Mercia, and substantially endowed. In 1540 it was surrendered to Henry VIII., who, in 1549, made a grant of it with all its lands and properties to his secretary Sir William Paget, the ancestor of the present lord of the manor, the marquis of Anglesey. In the time preceding the foundation of the abbey, the importance of the town was probably equal to that of the majority of Saxon boroughs, but it seems subsequently to have made but little progress, and even to the close of the 16th century to have had its character and condition mainly determined by the fact of its being the centre of an important ecclesiastical district. Notwithstanding the situation of the town being such as to have made it always the key to one of the great high roads between the Midland Counties, it does not seem to have been at any time fortified. It was the scene, however, of many frays. Especially notable is the battle which was fought at the Old Bridge on the 18th of March 1321, between the forces of Edward II. and Thomas earl of Lancaster, in which the latter was defeated.

During the civil war of the 17th century, Burton was repeatedly taken and re-taken. The consequences to the town were serious, entailing permanent injury to its interests in trade. Previous to the outbreak of the war the woollen trade had been the staple of the town, although it had also long been noted for its alabaster works, but the frequent plunderings of that unquiet time all but ruined these industries.

In the year 1255 the greater part of the town was destroyed by fire, and in 1514 it was nearly swept away by floods. The latter form of disaster has frequently recurred. In 1771, in 1792, in 1795, in 1852, and twice in 1875 the town was visited by heavy floods, which inundated the greater part of it, and inflicted considerable damage. In 1875 the depth of water in several streets was from 4 to 5 feet, and the current strong and dangerous.

In the year 1698 an Act of Parliament was obtained for making the Trent navigable as far as Burton, and for many years the "Burton Boat Company," as it was called, did good service as carrying-agents for the trade of the town. The opening of the Midland Railway in August 1839 was followed by results more marked even than such as have commonly attended the introduction of railways. The progress of the town since that date has been constant and

for the last twenty years remarkably and increasingly rapid.

During the earlier years of the present century the cotton mills of Burton were so extensive as to give employment to several hundred hands, but since 1849 the cotton trade has been discontinued. The demands of the brewing trade of late years, both as regards space and labour, seem to have made it difficult for any competing industry to exist. At any rate it must be admitted that at the present time the town derives all its commercial prosperity from the manufacture of ale, the recognized superiority of which is in a great measure due to the fact that the water used in its production, and obtained from wells sunk in the neighbourhood of the breweries, is impregnated with sulphate of lime derived from the gypseous deposits of the district. The brewing trade of Burton is comparatively of recent development, although the brewing of superior ale within the town was undoubtedly known as one of the features of the place in the days when the abbey flourished. The trade, as distinguished from private brewing, is reckoned to have commenced about the year 1708, and forty years later it had so extended as to have found a market at St Petersburg and the Baltic ports. In the year 1796, so flourishing had the trade become that there were then in the town no fewer than nine brewing firms. That most famous of Burton ale products known as "India Pale," or "Bitter Beer," was first manufactured, as a beverage suited to the climate of the East, about the year 1823, and for some years India was its only market. The favour it has since obtained at home it owes to accident. A vessel carrying some hogsheads of India pale ale was lost in the channel, and its cargo sold for the benefit of the underwriters. In this way it was that bitter beer first became known as a beverage in this country, and so rapid was its popularity, that since 1828 the pale ale trade has taken the lead in the commercial transactions of the town. The development of the Burton brewing trade generally from that date to the present time has been marvellous, but especially so since 1862 The magnitude which it has now attained may be inferred from the following facts and statistics. There are in all some thirty breweries in the town, the largest of which are those of Messrs Bass & Co. and of Samuel Allsopp & Sons. Last year (1875) the quantity of malt mashed in the several breweries together was 737,190 quarters, to contain which in the form of ale would require 2,948,761 barrels of 36 gallons each. The average price per barrel being 48s., we are enabled to set down the amount of brewing business done in the town, in one year alone, at £7,000,000. A calculation has been made by which it has been found that if all the barrels (2,948,761) of ale brewed in twelve months were put end to end in a straight line, that line would measure no less than 1535 miles. The Messrs Bass & Co. alone brew 250,000 quarters per annum; S. Allsopp & Sons alone 200,000 quarters. The business premises of the former firm cover 50 acres of freehold and 100 acres of leasehold property. Traversing these premises they have six miles of railway and six locomotives their own exclusive property. They employ over 2000 men and boys, and pay in wages to employés in Burton alone about £2000 per week. S. Allsopp & Sons have also private lines of railway, extending over 10 miles. These lines, Allsopp's and Bass's and others, as they connect with the outer railway system, intersect the town at many points. The amount paid to the several railway companies (Midland, North Staffordshire, and London and North Western) by the several brewing firms for carriage of ale in the course of 1875 for that year alone was £517,665.

The sanitary conditions of the town has been greatly improved since the passing of "Burton-upon-Trent Act, 1853." Under this Act, the town is divided into three wards, the Burton-upon-Trent Ward, the Burton Extra Ward, and the Horninglow Ward; and the local government is vested in a board of commissioners, twenty-seven in number, elected by the wards. Of public works in Burton the most notable is the New Bridge over the Trent, which was erected at a cost of £20,000, and was opened for traffic on the 22d June 1864. It is 469 yards in length, and has twenty-nine arches, supported by light but solid buttresses. The old bridge, which this one superseded, was of a curved form and extremely narrow. It had thirty-four arches, and is said to have been the longest bridge in the kingdom. The new cemetery, which occupies a plot of land 12 acres in extent, is situated in the township of Stagenhill, and was constructed at a cost of £13,000. It is divided into three parts, devoted to the separate burial of members of the Church of England, of nonconforming churches, and of the Church of Rome. It contains two mortuary chapels, and the house of the registrar.

Although, in some old records, Burton is styled a borough, it is certain it was not possessed of a charter of incorporation, nor has it yet obtained one. The police are those of the county. About five years ago the Burton Infirmary was opened, and has since been considerably enlarged. A new post-office is being erected, of dimensions suitable to the increasing growth of the town. There are three local newspapers published weekly. On the Derbyshire side of the river, and skirting its bank is the public recreation ground. The principal banking firm is the "Burton, Uttoxeter, and Ashbourne Union Bank," established 1839.

Burton is included in the diocese of Lichfield. Besides the Church of England, which has seven places of worship, there are the following denominations represented,—Presbyterian, Congregational, Wesleyan, Baptist, Free Church Methodist, Primitive Methodist, and Roman Catholic. The educational interests of the town are well cared for, there being, besides board schools, a grammar school, an endowed school, and three other schools of a voluntary character.

Commensurate with the increase of trade has been the increase of population. In 1801, when the first census was taken, it was a very little over 6000. From that year onwards to 1851 it steadily but very gradually increased. The ten years ending 1861 show the first great advance, the population being then 17,358. In 1871 it had grown to 23,748, and as the increase since then has been at the rate of over 1000 per annum, the population cannot now (1876) be less than 30,000.

BURTSCHEID, or Borcette, a town of Prussia, in the government of Aix-la-Chapelle (Aachen), and immediately to the S.E. of that city, with which it is connected by lines of houses. It occupies the slopes of a hill on the Wormfluss, and, like Aix-la-chapelle, is famous for its mineral springs. One of these, known as the Mill-bath spring, is the hottest of Central Europe, having a temperature of 155° Fahr. The water is employed both externally and internally, and the establishments for its use are extensive and convenient. The town carries on the manufacture of woollen yarn and cloth, cast-iron goods, and machinery, and possesses an important trade. Burtscheid grew up round a Benedictine monastery, founded probably in the 10th century by Gregory, son of the Greek emperor Nicephorus Phocas, and brother-in-law of Otto II. of Germany, and is said to have taken its name of *Porcetum* from the number of wild swine in the neighbourhood. In the 13th century the Benedictines became defunct, and a number of nuns from the convent of St Salvatorberg, near Aix-la-Chapelle, entered into possession. Their establishment continued till 1802, when it was broken up by the French. Population in 1872, 10,081.

BURU, Boero, or Bouro, an island of the East Indian Archipelago, belonging to the residency of Amboyna, and

situated about 250 miles E. of Celebes. According to Melvill von Carnbée it has an area of 3487 square miles, and extends from 3° 18′ to 3° 50′ S. lat. Its surface is for the most part very mountainous, though the seaboard district is frequently alluvial and marshy from the deposits of the numerous rivers by which the island is traversed. Of these, estimated at no less than 125, comparatively few are navigable except the Kayeli or Wai Apoe, which is the largest of all. The principal peaks are the Tomahoe (Kapâla-Lemadang, Saniane or Buru-dome), 8529 feet in height, the Filehet, and the Palamatta. In the middle of the western portion of the island lies the large lake of Wakaholo, with a circumference of 37 miles, and a depth of about 100 feet. By far the larger part of the country is covered with natural forest and prairie land, but such portions as have been brought into cultivation are highly fertile. Coffee, rice, and a variety of fruits, such as the lemon, orange, banana, pine-apple, and cocoa-nut are readily grown, as well as sago, red-pepper, tobacco, and cotton. The only important export, however, is cajeput oil, a sudorific distilled from the leaves of the *Melaleuca Cajuputi*, or white-wood tree, of which about 8000 bottles are manufactured annually and sent to Java and other parts of the archipelago. The native flora is very rich, and the teak, ebony, and canari trees are especially abundant. Among the animals are buffaloes, hogs, deer, crocodiles, lizards, and snakes; and ducks, doves, cockatoos, and birds of paradise are the chief representatives of the feathered species. According to Mr Wallace, the inhabitants are mainly of two partially amalgamated races—Malays on the sea-coast like those of Celebes, and Alfuros in the interior akin to those in Ceram. The latter are still completely pagan, live in scattered hamlets, and have come very little in contact with any civilization. Among the maritime population a small number of Chinese, Arabs, and other races are also to be found. The island is divided by the Dutch into the regencies of Kayeli, Ilat, Lumaëteh, Waaisama, Massareteh, Foggi, Bara, Licella, Talisa, Marulat, and Leliali. The village of Kayeli is inhabited by eleven Mahometan tribes, who were compelled by Arnold de Vlaming in 1657 to gather together from the different parts of the island, while all the clove-trees were mercilessly exterminated. Before the arrival of the Dutch the islanders were under the dominion of the sultan of Ternate; and it was their rebellion against him that gave the Europeans the opportunity of effecting their subjugation. In 1854 the port of Kayeli was declared free to all nations without customs on either ship or cargo.

BURY, a manufacturing town and parliamentary borough of England, in the county of Lancaster, on the Irwell, 8 miles N.N.W. of Manchester. The woollen-trade, introduced in the 14th century, and of such importance in the reign of Elizabeth that she appointed an officer to stamp the cloth, still gives employment to 1000 of the population, but it has been greatly surpassed in extent by the cotton manufacture, which with its various branches gave employment in 1872 to 16,256 men and women of the age of twenty years or upwards. The auxiliary and supplemental trades of engine-making, spindle-making, calico-printing, bleaching, and dyeing are also largely carried on; the paper manufacture employs about 600 people; upwards of 1000 miners find work in the neighbouring coal-pits; 1200 workmen are engaged in the iron manufacture, and nearly 200 in the stone quarries. The town has been not only greatly extended but also greatly improved since the middle of the century; it is well drained, and has a good supply of water. It contains a town-hall, an athenæum (including a museum), a free grammar school, founded by the Rev. Roger Kay, a mechanics' institute, and several public libraries. The parish church of St Mary's was rebuilt in 1776. The government, which was at one time in the hands of three constables, appointed by the earl of Derby, the lord of the manor, was afterwards entrusted to a board of commissioners under a local Act; but the town has applied for municipal incorporation. Bury is a place of considerable antiquity, and was formerly the seat of a baronial castle, which was destroyed by the Parliamentary forces in 1644. Sir Robert Peel was born at Chamber Hall in the neighbourhood, and his father did much for the prosperity of the town by the establishment of extensive printworks. A monument to the statesman now adorns the market-place. The parliamentary borough, which comprises the townships of Bury and Elton, has returned one member to Parliament since the Reform Bill of 1832. Its population in 1871 was 41,344, of whom 19,849 were males, and 21,495 females; the inhabited houses numbered 8279, and the registered electors 5518.

BURY, RICHARD DE. See AUNGERVYLE, vol. iii. p. 85.

BURY ST EDMUNDS, a market-town and municipal and parliamentary borough of England, in the county of Suffolk, on the Lark, 26 miles N.W. of Ipswich, and 71 miles from London. It is governed by a mayor, six aldermen, and eighteen councillors, and returns two members to Parliament. The town is pleasantly situated on a gentle eminence, in a fertile and richly cultivated district, is clean and well built, and has a good drainage system. It is supposed to be the *Villa Faustini* of the Romans, and numerous Roman remains have been dug up on the spot. It was the Beodericsworth of the Saxons, and by them was made a royal town of East Anglia. Its present name is derived from St Edmund, the king and martyr, who was taken prisoner and put to death by the Danes in 870. In 1020 a monastery was founded there by Canute, which for magnificence and splendour surpassed every other establishment of the kind in Britain, with the exception of that of Glastonbury. It was 505 feet long and 212 wide, and contained twelve chapels. The abbot had a seat in Parliament, with the power to inflict capital punishment, and judged in all civil causes within the liberty. The privilege of coining was granted to the abbot by Edward the Confessor, and both Edward I. and Edward II. had mints in the town. In 1327 the people of the town and neighbourhood attacked the monastery and reduced a large part of it to ashes. The tower or church-gate, one of the finest specimens of Norman architecture in the kingdom, and the western gate, erected about the middle of the 14th century, with a small portion of the walls, are all that now remains of that magnificent structure. St Mary's church, a fine Gothic edifice, with a beautifully carved roof, was erected in the earlier part of the 15th century, and contains the tomb of Mary Tudor, Queen of Louis XII. of France. St James's church is also a very fine building, containing several handsome monuments. The free grammar school, founded by Edward VI., has two scholarships at Cambridge, and six exhibitions to each university. The town has a shire-hall where assizes for the county and liberty are held, a handsome and commodious corn exchange, a guildhall, news and assembly rooms, a theatre, a savings-bank, botanic gardens, a county jail, a general hospital, and about 100 almshouses. The market-days are Wednesday and Saturday. Wednesday's market is very important, both for corn and cattle, but particularly for the latter, being second only to that of Norwich, which is the largest in the Eastern counties. About a mile below the town the river becomes navigable for barges to Lynn, whence coals and other commodities were formerly brought, but of late years, since the formation of the railway, the river has been but little used.

There are four lines of railway,—in connection with London and Cambridgeshire for the north, Thetford to Norwich and West Norfolk, Ipswich and East Suffolk, and Colchester for Essex. In the vicinity is Ickworth, the magnificent seat of the marquis of Bristol. The town was the birthplace of Bishop Gardiner, and gives the title of viscount to the Keppel family (Earls of Albemarle). Population in 1871, 14,928.

BUSBECQ, AUGIER GHISLEN DE (1522–1592), a Flemish diplomatist and traveller, was born at Commines in 1522, and was educated at the universities of Louvain, Paris, Venice, Bologna, and Padua. He was engaged in several important employments and negotiations, and in particular was twice sent as ambassador by the Emperor Ferdinand I. to the court of Soliman II. He made a collection of curious inscriptions and manuscripts; and in his second journey to Constantinople he carried with him an artist to make drawings of the rarest plants and animals. In 1562 he returned to Vienna, and was appointed tutor to the sons of the Emperor Maximilian II. Busbecq died at St Germain, near Rouen, October 28, 1592. He wrote a *Discourse of the State of the Ottoman Empire*, and a *Relation of his Two Journeys to Turkey*. A translation of the Travels in Turkey was published in Glasgow by Robert Urie in 1761.

BUSBY, RICHARD (1606–1695), D.C.L., head-master of Westminster school, was born at Lutton in Lincolnshire in 1606. He was educated at the school which he afterwards superintended for so long a period, and first signalized himself by gaining a king's scholarship. From Westminster he removed to Christ Church College, Oxford, where he graduated in 1628. In his thirty-third year he had already become renowned for the obstinate zeal with which he supported the falling dynasty of the Stuarts, and was rewarded for his services with the prebend and rectory of Cudworth, with the chapel of Knowle annexed, in Somersetshire. Next year he became head-master of Westminster school. His reputation as a teacher soon became so great that many of the noblest families entrusted their children to his care. He himself once boasted that sixteen of the bishops who then occupied the bench had been birched with his "little rod." No school in England has on the whole produced so many eminent men as Westminster did under the régime of Busby. Among the more illustrious of his pupils may be mentioned South, Dryden, Locke, Prior, and Bishop Atterbury. He wrote and edited many works for the use of his scholars. His original treatises (the best of which are his Greek and Latin grammars), as well as those which he edited, have, however, long since fallen into disuse. Busby died in 1695, in his ninetieth year, and was buried in Westminster Abbey, where his effigy is still to be seen.

BUSCA, a town of Italy, in the province of Cuneo, 9 miles from the city of that name, on the left bank of the Macra, a confluent of the Po. It contains a college, a hospital, and two botanic gardens. The inhabitants are engaged in the culture of the silkworm and the manufacture of leather and ironwares; and there are marble and alabaster quarries. It is the site of some Roman antiquities. Population, 9533.

sensible of the defective state of geographical science, and resolved to devote his life to its improvement. Withdrawing as soon as possible from the count's family, he went to reside at Copenhagen, and devoted himself entirely to this new pursuit. In 1752 he published a *Description of the Counties of Schleswig and Holstein*, a work that was much approved. In 1754 he removed to Göttingen, and married Christiana Dilthey, a young lady of some temporary reputation as a poetess. Here a work in which he dissented from some of the Lutheran tenets lost him the appointment in 1757 to the theological chair, for which he had become a candidate. Two years later he was appointed professor of philosophy; but in 1761 he accepted an invitation to the German congregation at St Petersburg. There he organized a school, which, under his auspices, soon became one of the most flourishing in the North of Europe, but a disagreement with Marshal Munich led him, in spite of the empress's offers of high advancement, to return to Germany in 1765. He first went to live at Altona; but next year he was called to superintend an extensive educational establishment, known as the Greyfriars Gymnasium (*Gymnasium zum Grauen Kloster*), which had been formed at Berlin by Frederick the Great. Here he superintended the progress of every pupil, and inspected the minutest details connected with the prosperity of the institution, besides giving lectures on the history of the arts and sciences. He continued to prosecute his various labours till a dropsy, under which he had long suffered, terminated his life on the 28th May 1793. His writings and example gave a new impulse to education throughout Prussia, and the Government was so sensible of the value of his services that they allowed his extensive correspondence to pass free of postage.

Few authors, even in Germany, have been more prolific than Büsching. As enumerated by Meusel in his *Lexicon of German Authors*, his works amount to more than a hundred. They may be classed under the heads of Geography and History, Education, Religion, and Biography. The first class comprehends those upon which his fame chiefly rests; for although he did not possess the geographical genius of D'Anville, he may be regarded as the creator of modern Statistics. His *magnum opus* is the *Neue Erdbeschreibung*, (*New Description of the Globe*). The first four parts, which comprehend Europe, were published in four volumes (1754–1761), and have been translated into many of the European languages. They appeared in English with a preface by Murdoch, in six volumes 4to, London, 1762. In 1768 the fifth part was published, being the first volume upon Asia, containing Asiatic Turkey and Arabia. It displays an immense extent of research, and is generally considered as his masterpiece. Büsching was also the editor of a valuable collection entitled *Magazin für Historie und Geographie*, 2 vols. 4to, 1767–93; also of *Wochentl. Nachrichten von neuen Landkarten*, Berlin, 1773–87.

His elementary works on education long held a distinguished place in this branch of literature, but his theological writings are not much esteemed. In biography he wrote a number of articles for the above mentioned *Magazin*, and a valuable collection of *Beiträge zur Lebensgeschichte merkwürdiger Personen*, 6 vols. 1783–9, including a very elaborate life of Frederick the Great.

BUSHIRE, or ABUSCHEHR, a town of Persia, in the province of Fars, situated in the Persian Gulf. The surrounding country is a parched and barren desert, consisting of brown sand or grey clay and rock, unenlivened by any kind of vegetation. The town, which is of a triangular form, occupies the extremity of a peninsula eleven miles long and four broad, and is encircled by the sea on all sides except the south. It is fortified on the land side by a mud wall with round towers. The houses being mostly built of white stone gives the city, when viewed from a distance, a rather clean and handsome appearance, but on closer inspection the streets are found to be narrow, irregular, ill-paved, and filthy. Almost the only handsome buildings are the sheikh's palace and the British residency. Ships of 300 tons are obliged to lie in the roads six miles from the town. The water immediately east of the town

is deep, but its navigation is impeded by a bar, which can only be passed by vessels drawing not more than 8 or 9 feet of water, except at spring-tides, when there is a rise of from 8 or 10 feet. Bushire carries on a considerable trade. particularly with Calcutta, Bombay, and Java. Its imports are indigo, sugar, rice, spices, steel, cotton and woollen goods, coffee, &c.; and its principal exports are raw silk, opium, Kerman wool, shawls, silk goods. carpets, horses, dried fruits, wine, grain, copper, turquoises, pearls, asafœtida, and gall-nuts. The climate is excessively hot particularly in the months of June, July, and August. The water is very bad; that fit for drinking requires to be brought in goat-skins from wells, distant 1½ mile from the city walls. The population is variously estimated at from 10,000 to 20,000.

The importance of Bushire has much increased of late years. It is now not only the headquarters of the English naval squadron in the Persian Gulf, and the land terminus of the Indo-European line of telegraph, but it also forms the chief station in these seas of the British Indian Steam Navigation Company, which runs its vessels weekly between Bombay and Bussorah, and it is further expected that, if our Foreign Jurisdiction Act should be applied to Persia, an appellate court will be formed at Bushire. In the meantime several European mercantile houses have been established in the town, and there can be no doubt that if the means of communication with the interior were improved, trade would rapidly increase. Notwithstanding, indeed, the drawbacks of bad roads, insufficient means of transport (wheeled carriages being unknown and beasts of burthen being few and dear), want of security, and illegal exactions, the annual value of the Bushire trade is now estimated at £600,000, of which one-quarter represents the exports and three-quarters the imports, the balance of trade against Persia at this single port thus amounting to about £300,000 a year, which is met by a constant drain of the precious metals to India. During the late war with Persia (1856–57) Bushire surrendered to a British force, and remained in our occupation for some months. The town yields a yearly revenue of about £15,000, mainly derived from customs, and is the chief place of a district, extending for 300 miles along the sea-coast from Dilem to Congoon, which is assessed in the Shiráz register at about £25,000 per annum. At Ríshire, in the vicinity of Bushire, there are extensive ruins, among which bricks stamped with cuneiform legends have been found, showing that the place was a very old Elamite settlement under the kings of Susa. It continued also to flourish under the name of Rív-Ardeshír, during the Sassanian period, and only fell into decay after the Arab conquest, its place as the great emporium of trade being successively taken by Siráf (the modern Táhiri), Keis, and Ormuz. The British commercial factory was transferred from Gombroon (modern Bander Abbáss) to Bushire during the last century; but the duties of the Bushire resident at present are exclusively political. (H. C. R.)

BUSHMEN, or Bosjesmans, so named by the British and Dutch colonists of the Cape, but calling themselves *Saab* or *Saan*, are an aboriginal race of South Africa, allied in some respects to the Hottentots, but differing from them in several essential points, and along with these having nothing whatever in common with the Kaffre or the Negro. The area in which they are found in nomadic families may be described as extending from the inner ranges of the mountains of Cape Colony, through the central Kalahari desert to near Lake Ngami, and thence north-westward to the districts about the Ovámbo River north of Damara Land, in about 18° S. lat., or only over the most barren portions of the South African deserts, into which they have been pressed by the encroachments of the Kaffre, Hottentots, and Europeans, a few also remaining in the most inaccessible clefts of the Drakenberg range about the sources of the Vaal. They rank with the savages of Australia as the lowest existing type of mankind, human nature being nowhere seen in a more destitute or degraded condition. The Bushmen with whom the colonists of the south have come most in contact are of very small stature, of a dirty yellow colour, and generally repulsive countenance. In type they somewhat resemble the Mongolians; the cheek-bones are large and prominent, the eyes deeply set and crafty in expression, the nose small and depressed; the hair appears in small woolly tufts with spaces between. Among 150 of their number measured by the traveller Barrow, the tallest man was 4 feet 9 inches, the tallest woman 4 feet 4 inches. A hollowed back and protruding stomach, with thick hinder parts and small limbs, are frequent characteristics of their figure, but many of them are well-proportioned, all being active and capable of enduring great privations and fatigue. Northward the Bushmen appear to improve both in general condition and in stature. Those met with towards Lake Ngami by Dr Livingstone are described by him as differing from those of the thirsty plains of the Kalahari, being of darker colour and of good proportions; some of those seen by the traveller Baines in this region are also noticed as being taller, some 5 feet 6 inches in height. Their clothing consists of a mantle of skins, termed a *kaross*; but they are fond of ornament, and decorate the arms and legs with beads and iron or copper rings, and the women sometimes stain their faces with red colour. For dwellings in the plains they have low huts formed of reed mats, or may simply occupy a hole in the earth; in the mountain districts they make a shelter among the rocks by hanging mats on the windward side. They do not possess cattle, and have no animals of any sort excepting a few half-wild dogs, nor have they the smallest rudiments of agriculture. Living by hunting, they are thoroughly acquainted with the habits and movements of every kind of wild animals, following the antelope herds in their migrations. Their weapon is a small bow, strung with twisted sinew, used with arrows, which are neatly made of a reed with a barbed head of bone, sometimes tipped with a triangular piece of iron, and always coated with a gummy poisonous compound, which is variously made in different localities. The chief sources of the poison are the milky juice of the *Amaryllis toxicaria*, which is abundant in South Africa, or of the *Euphorbia arborescens*, generally mixed with the venom of snakes or of a large black spider of the genus *Mygale*; or the entrails of a very deadly caterpillar, called N'gwa or 'Kaa, are used alone. From their use of these poisons the Bushmen are held in great dread by the neighbouring races. A rude implement, called the *graaf stock* or digging-stick by the boers,—consisting of a sharpened spike of hardwood over which a stone, ground to a circular form and perforated, is passed and secured by a wedge,—is used by the Bushmen in uprooting the succulent tuberous roots of the several species of creeping plants of the desert. These perforated stones have a special interest in indicating the former extension of the race of the Bushmen, since they are found far beyond the area now occupied by their families.

There does not appear to be the least approach to any tribal unity in the wandering groups of the Bushmen; they have no chiefs, bodily strength alone forming a distinction among them. Their language, which exists in several dialects, is not intelligible to the Hottentots, but has in common with it the nasal, snapping, hissing, or grunting sounds, only used more numerously. The Hottentot language is more agglutinative, the Bushman's more monosyllabic; the former recognizes a gender in names, the latter does not; the Hottentots form the plural by a suffix.

the Bushmen by repetition of the name; the former count up to twenty, the latter can only number two, all above that being "many." The Bushmen possess a remarkable faculty which is not known in any other South African natives, that of graphic illustration; the rocks of the mountains of Cape Colony and of the Drakenberg have everywhere examples of Bushman drawings of men, women, children, and animals characteristically sketched. Rings, crosses, and other signs drawn in blue pigment on some of the rocks, and believed to be some centuries old, have given rise to the speculation that these may be remains of a hieroglyphic writing; and the discovery of drawings of men and women, with antelope heads, in the recesses of the Drakenberg in 1873 (Orpen in *Cape Monthly Magazine*, July 1874), also very ancient, recalls the mythological figures of Egypt. The Bushmen are not deficient in a certain intelligence, and are valued as servants by the boers, being much more energetic than the Hottentots; of all the South African races they have the greatest aptitude for music and the dance. A regularly planned and wholesale destruction of this race on the borders of the colony in the earlier years, reduced their numbers to a great extent; and though this cruel hunting of the Bushmen has ceased, their children are still captured by the boers as servants. In retaliation, the Bushmen have long been the scourge of the farms on the outer borders of the colonies, making raids on the cattle and driving them off in large numbers. On the western side of the deserts they are generally at enmity with the Koranna Hottentots, but on the eastern border of the Kalahari they have to some extent become tributary to the Bechwana Kaffres. Formerly occupying a much larger area, it appears probable that the Bushmen are the earliest remaining aborigines of South Africa, and that they existed there before the Kaffres, and perhaps also anterior to the Hottentots. The discoveries of the dwarf race of the Akka by Dr Schweinfurth beyond the Upper Nile basin, of the little Bushman-like Obongo on the western equatorial coastland by Du Chaillu, and of the Okota, an undersized people leading a miserable existence in bark huts on a branch of the Ogowé River, by De Compiègne in 1874, point to a former more general distribution of this primitive race.

Barrow's *South Africa*, 1801-3; Burchell's *Travels*, 1822; Livingstone's *Missionary Travels*, 1857; Baines's *Explorations*, 1864; Merensky's *Süd-Afrika*, 1875.

BUSHNELL, Horace, D.D. (1802–1876), an American theologian, was born at Litchfield in Connecticut, in April 1802, and died on the 17th of February 1876. He studied at Yale College, where he graduated in 1827, after which he was for eleven months editor of the *Journal of Commerce*, and then teacher in a school in Norwich (Connecticut). In 1829 he became tutor in Yale College. His first study was law, but in 1831 he resolved to devote himself to theology, and in 1833 he was chosen pastor of the North Congregational Church in Hartford (Connecticut), where he remained twenty-four years. During the remainder of his life he had no settled charge, but he continued to be diligently employed both as a preacher and as an author. He took an active part in the establishment of the university of California, and was asked to become its president. Having determined to value truth more highly than peace or consistency, Bushnell thought, and expressed his conclusions, with such freedom as to bring on himself a charge of false doctrine. In 1849 he published *God in Christ*, with an introductory *Dissertation on Language as related to Thought*, in which, it was said, he expressed heretical views as to the Trinity. He was acquitted by seventeen votes to three, but his influence with his church was such that it withdrew from the "Consociation" by which he had been tried, and thenceforward stood alone, a true "congregational" church, whose minister was amenable to no external authority. Bushnell formally replied by writing *Christ in Theology*, in which he employs the important argument that spiritual facts can only be expressed in approximative and poetical language, and concludes that an adequate dogmatic theology cannot exist. That he did not deny the divinity of Christ he proved in *The Character of Jesus, forbidding his possible classification with Men*. He has also published *Christian Nurture*, (1847); *Sermons for the New Life*, (1858); *Nature and the Supernatural*, (1858); *Christ and his Salvation*, (1864); *Work and Play*, (1864); *The Vicarious Sacrifice, grounded on Principles of Universal Obligation*, (1865); *Moral Uses of Dark Things*, (1868); *Sermon on Living Subjects; Women's Suffrage, the Reform against Nature*, (1869); and *Forgiveness and Law*, (1874).

BUSIRIS, the name of a mythical king of Egypt not found either on the monuments or in the chronological lists, but mentioned by the later Greek writers and mythologists. By Apollodorus he was made the son of Ægyptus, and an Egyptian king, or else the son of Poseidon and Lyssianassa. After Egypt had been afflicted for nine years with famine Phrasius, a seer of Cyprus, arrived in Egypt and announced that the cessation of the famine would not take place until a foreigner was yearly sacrificed to Zeus or Jupiter. Busiris commenced by sacrificing the prophet, and continued the custom by offering a foreigner on the altar of the god. It is here that Busiris enters into the circle of the myths and *parerga* of Heracles, who had arrived in Egypt from Libya, and was seized and bound ready to be killed and offered at the altar of Zeus. Heracles burst the bonds which bound him, and, seizing his club, slew Busiris with his son Amphidamas, and his herald Chalbes. This exploit is often represented on vase paintings, the Egyptian monarch and his companions being represented as negroes. Although some of the Greek writers made Busiris an Egyptian king and a successor of Menes, about the sixtieth of the series, and the builder of Thebes, those better informed by the Egyptians rejected him altogether; they do not even admit that he was the lieutenant of Osiris set over the lands opposite Phœnicia and the Mediterranean, nor do they recognize him as living two centuries after Perseus and later than Heracles. Various esoterical explanations were given of the myth, and the name not found as a king is recognized in that of one or more cities of the same name in Northern Egypt. The legend was unknown both to Homer and to Hesiod, and appears after the Greeks were more intimately acquainted with Egypt, and had seen the wall-paintings, or imperfectly understood the popular tales and traditions of the people, for there is no solid reason to believe that human sacrifices were ever offered in the country.

BUSIRIS, the name of an Egyptian town, the capital of the Busirites nomos, or Busirite nome, called in the hieroglyphs Pa-osiri, or Place of Osiris, the eponymous deity of the place. It is the modern Abusir, and lay, according to Herodotus, in the middle of the Delta. It was supposed to be close to the entrance of the gates of the *Aahlu*, or Elysium, and the nome to be that called in the hieroglyphs Kahebs; and Busiris itself may have been the Egyptian *Tattu*. Close to the town, which lay on the Phatnitish or Pathmitish arm of the Nile, was the pyramid of the king Sahura, the successor of Uskafan, a king of the 4th dynasty; this was called the *Sa-ba*, or pyramid of the "Rising Soul," and some supposed that the name *Pa-sahura*, or "city of Sahura," may have been the origin of the name Busiris instead of *Pa-osiri*. The later Greek authors gave many different versions of the name mixed up with their own mythology, such as that Isis had there interred Busiris in the wooden figure of a cow, and that the place was hence called Bousosiris, or that the goddess had there buried

Osiris, when killed by Typhon, in the body of the same animal enveloped in bandages—legends evidently confused with the burial of the Apis in the Serapeum which lay in the vicinity. The shrine of the goddess Isis was situated in it, and a great annual festival and lamentation of Osiris held there, which appears from an inscription of the temple of Denderah to have taken place on the 14th day of the month Choiak. At the time of the privilege, conferred on the nomes of Egypt by the Emperor Hadrian, of coining the money struck at the time of his visit to that country, and dated in the 11th year of his reign 117 A.D., the Busirite nome issued small bronze pieces on which is the goddess Isis standing holding a cow or goat in one hand and a serpent in the other. Demetrius of Phalerum, the philosopher, exiled by Ptolemy Philadelphus, is said to have died at Busiris 284 B.C., having put an end to his life by the bite of an asp. The city was destroyed by the Emperor Diocletian in the 3d century A.D., but the Copts and Arabs have preserved its name in Bousiri and Abusir. Another village of the same name is supposed to have existed in the Letopolite nome.

BUSSORAH, BASSORA, BALSORA, or BASRA, a celebrated city of Asia, in the government of Baghdad, situated in 47° 34′ E. long., 30° 32′ N. lat., on the western banks of the Shatt-el-Arab. It is about 70 miles from the mouth of that noble stream, which is navigable to the city for ships of 500 tons burden after passing the bar at its mouth; this, however, they can only conveniently do at spring-tides. Bussorah is surrounded by walls, which are kept in a tolerable state of repair. They have five gates, and are at the lowest computation about seven miles in circuit. Two canals, cut from the river, surround the town on either side; and uniting beyond it on the western side, form a complete ditch to the fortifications. The houses are meanly built, partly of sun-dried and partly of burnt bricks, with flat roofs surrounded by a parapet; and the bazaars, though stocked with the richest merchandise, are miserable structures, not arched as in Baghdad and the Persian towns, but covered with mats laid on rafters of date trees, which hardly afford protection from the scorching rays of the sun. The streets are irregular, narrow, and unpaved, and the town itself is disgustingly filthy. Of the vast area within the walls, the greater proportion is occupied with gardens and plantations of palm trees, intersected by a number of little canals, cleansed twice daily by the ebb and flow of the tide, which rises here about 9 feet. The largest of these canals, which approaches the old English factory and the palace of the governor, situated about two miles from the river, is continually crowded with small vessels. The town has scarcely any public buildings that deserve notice. It has khans and coffee-houses without number, a wretched hummam (or bath), and upwards of forty mosques, of which one only is worthy of the name; and this, with the palace of the governor, and the old English factory, which are all contiguous to one another, are the only decent buildings in the place. The old English factory, which was established at Bussorah by the East India Company, about the middle of the last century, ceased to exist with the expiration of the trading privileges of the company. The building has now passed into private hands, and the British vice-consul, who protects our trading interests, resides at the modern village of Maghil, which has been built in a healthy position on the right bank of the river a few miles from the Turkish town. The population of Bussorah is a heterogeneous mixture of all the nations in the East, and consists of Turks, Arabs, Indians, Persians, Armenians, Jacobites, and Jews. The Arabs constitute the principal class; and the Turks, though they are masters of the town, are almost the least numerous.

Bussorah is a great emporium of Indian commerce. Six or eight English ships arrive in the course of a year from India; but the chief part of the traffic is carried on in Arabian bottoms; and the merchants of Muscat possess some of the finest vessels that navigate the Indian seas. From various parts of Hindustan Bussorah receives silk, muslin, linen, white and blue cloths for the clothing of the Arabians, gold and silver stuffs, various metals, sandal-wood, and indigo; pearls from Bahrein, and coffee from Mocha; shawls, fruit, and the precious metals from Persia; spices from Java; and European commodities, which are scarce and dear, from different parts. The trade with the interior is conducted by means of caravans to Aleppo and Baghdad, whence the goods are conveyed to Constantinople. The returns are made in Indian goods, bullion, pearls, dates, copper, raw silk, gall-nuts; and the horses, which are very strong and beautiful, are exported in large numbers by the English.

The situation of the town is unhealthy, owing to the inundations of the river, from which noxious exhalations arise; and strangers are commonly attacked by fever after a short residence. The adjoining country is fertile, producing, besides rice, wheat, barley, and dates of different species, a variety of fruits and vegetables, such as apricots, apples, figs, olives, pomegranates, and grapes; and cabbages, broccoli, lettuce, onions, pease, beans, and truffles, in vast quantities. There are whole fields of roses, which the inhabitants cultivate for the purpose of making attar. The liquorice plant also grows amidst the palm groves on the borders of the river.

The city of Bussorah was originally founded by Omar, 636 A.D., on a canal eight miles S.W. from its present site, where the town of Zobeir now stands; and its situation was so favourable for commerce that in a few years it became a large and flourishing city. The canal, however, soon became useless, and the city was abandoned. The present city was conquered by the Turks in 1668, and since that period has been the scene of many revolutions. It was taken in 1777 after a siege of eight months, by the Persians under Sadick Khan. In about a year it fell again into the hands of the Turks, who were again deprived of it by the sheikh of the Montefik Arabs. The town was in the October following recovered by Soliman Pasha, who encountered the sheikh on the banks of the Euphrates, and put him to flight; and it has since remained in the hands of the Turks.

Under the government of the Turks Bussorah has dwindled down to a mere second-rate town, the permanent population at present (1876) being certainly under 10,000. In the river there is perhaps a greater show of activity just now than in past times, as the Turks employ a considerable naval force in the Persian Gulf to support their land operations against the Arabs, and the Bussorah roads form the headquarters of the squadron, while two or three Turkish steamers also ply upon the river, and have their depôts upon its bank. There are two steamers also belonging to the Tigris and Euphrates Navigation Company (besides a war steamer maintained by the British Government in virtue of a special firman), which convey merchandise and passengers between Baghdad and Bussorah; and, lastly, the vessels of the British India Steam Navigation Company visit Bussorah every week from Bombay and Bushire; but as the trade fostered by these means is entirely one of transit, it confers little benefit on the town or its inhabitants. The village of Maghil, however, on the banks of the Euphrates, at the distance of three or four miles from Bussorah, where the wharves and store-house of the European

companies are situated, is becoming a considerable place, and may be expected ultimately to supersede the Turkish town. The terminus of the Constantinople line of telegraph, which furnishes an alternative means of communication between England and India, is at Fáo, near the mouth of the Euphrates, and at the distance of about 60 miles below Bussorah. A good deal of attention has of late years been directed to Bussorah in connection with the proposal for a railway to unite the Mediterranean with the Persian Gulf, either by way of the Tigris or Euphrates valley. In no case, however, would it be desirable to establish the terminus of such a railway at Bussorah, where the climate would prove most destructive to European life. The most eligible site for the terminus would be either at Kowait on the sea-coast, 50 miles south of Bussorah, or at the Persian town of Mohamreh, where the Karún River disembogues into the Euphrates. Quite recently the Turkish Government has decided to dissociate the Bussorah district, with its dependencies, from Baghdad, and to attach it to the newly-created province of Arabia, the headquarters of the pashalic being established at El Hassa; but such an arrangement is not likely to be permanent. (H. C. R.)

BUSTARD (corrupted from the Latin *Avis tarda*, though the application of the epithet[1] is not easily understood), the largest British land-fowl, and the *Otis tarda* of Linnæus, which formerly frequented the champaign parts of Great Britain from East Lothian to Dorsetshire, but of which the native race is now extirpated. Its existence in the northern locality just named rests upon Sibbald's authority (*circa* 1684), and though Hector Boethius (1526) unmistakably described it as an inhabitant of the Merse, no later writer than the former has adduced any evidence in favour of its Scottish domicile. The last examples of the native race were probably two killed in 1838 near Swaffham, in Norfolk, a district in which for some years previously a few hen-birds of the species, the remnant of a plentiful stock, had maintained their existence, though no cock-bird had latterly been known to bear them company. In Suffolk, where the neighbourhood of Icklingham formed its chief haunt, an end came to the race in 1832; on the wolds of Yorkshire about 1826, or perhaps a little later; and on those of Lincolnshire about the same time. Of Wiltshire, Montagu, writing in 1813, says that none had been seen in their favourite haunts on Salisbury Plain for the last two or three years. In Dorsetshire there is no evidence of an indigenous example having occurred since that date, nor in Hampshire nor Sussex within the present century. From other English counties, as Cambridgeshire, Hertfordshire, and Berkshire, it disappeared without note being taken of the event, and the direct cause or causes of its extermination can only be inferred from what, on testimony cited by Mr Stevenson (*Birds of Norfolk*, ii. pp. 1–42), is known to have led to the same result in Norfolk and Suffolk. In the latter the extension of plantations rendered the country unfitted for a bird whose shy nature could not brook the growth of covert that might shelter a foe, and in the former the introduction of improved agricultural implements, notably the corn-drill and the horse-hoe, led to the discovery and generally the destruction of every nest, for the bird's chosen breeding-place was in wide fields—"brecks," as they are locally called,—of winter-corn. Since the extirpation of the native race the Bustard is known to Great Britain only by occasional wanderers, straying most likely from the open country of Champagne or Saxony, and occurring in one part or another of the United Kingdom some two or three times every three or four years, and chiefly in midwinter.

An adult male will measure nearly four feet from the tip of the bill to the end of the tail; and its wings have an expanse of eight feet or more,—its weight varying (possibly through age) from 22 to 32 pounds. This last was that of one which occurred to the younger Naumann, the best biographer of the bird (*Vögel Deutschlands*, vii. p. 12), who, however, stated in 1834 that he was assured of the former existence of examples which had attained the mass of 35 or 38 pounds. The female is considerably smaller. Compared with most other birds frequenting open places the Bustard has disproportionately short legs, yet the bulk of its body renders it a conspicuous and stately object, and when on the wing, to which it readily takes, its flight is not inferior in majesty to that of an Eagle. The bill is of moderate length, but, owing to the exceedingly flat head of the bird, appears longer than it really is. The neck, especially of the male in the breeding-season, is thick, and the tail, in the same sex at that time of year, is generally carried in an upright position, being, however, in the paroxysms of courtship turned forwards, while the head and neck are simultaneously reverted along the back, the wings are lowered, and their shorter feathers erected. In this posture, which has been admirably portrayed by Mr Wolf (*Zool. Sketches*, pl. 45), the bird presents a very strange appearance; for the tail, head, and neck are almost buried amid the upstanding feathers before named, and the breasts are protruded to a remarkable extent. The Bustard is of a pale grey on the neck and white beneath, but the back is beautifully barred with russet and black, while in the male a band of deep tawny-brown—in some examples approaching a claret-colour—descends from either shoulder and forms a broad gorget on the breast. The secondaries and greater wing-coverts are white, contrasting vividly, as the bird flies, with the black primaries. Both sexes have the ear-coverts somewhat elongated—whence doubtless is derived the name *Otis* (Gr. ὠτίς)—and the male is adorned with a tuft of long, white, bristly plumes, springing from each side of the base of the mandible. The food of the Bustard consists of almost any of the plants natural to the open country it loves, but in winter it will readily forage on those which are grown by man, and especially coleseed and similar green crops. To this vegetable diet much animal matter is added when occasion offers, and from an earth-worm to a field-mouse little that lives and moves seems to come amiss to its appetite.

Though not many birds have had more written about them than the Bustard, much remains to be determined with regard to its economy. A moot point, which will most likely always remain undecided, is whether the British race was migratory or not, though that such is the habit of the species in most parts of the European continent is beyond dispute. Equally uncertain as yet is the question whether it is polygamous or not—the evidence being perhaps in favour of its having that nature. But one of the most singular properties of the bird is the presence in some of the fully-grown males of a pouch or gular sack, opening under the tongue. This extraordinary feature, first discovered by James Douglas, a Scotch physician, and made known by Albin in 1740, though its existence was hinted by Sir Thomas Browne sixty years before, if not by the Emperor Frederick II., has been found wanting in examples that, from the exhibition of all the outward marks of virility, were believed to be thoroughly mature; and as to its function and mode of development judgment had best be suspended, with the understanding that the old supposition of its serving as a receptacle whence the bird might supply itself or its companions with water in dry places must be deemed to be wholly untenable. The structure of this pouch—the existence of which in some examples has been well established,—is, however, variable;

[1] It may be open to doubt whether *tarda* is here an adjective. Several of the mediæval naturalists used it as a substantive.

and though there is reason to believe that in one form or another it is more or less common to several exotic species of the family *Otididæ*, it would seem to be as inconstant in its occurrence as in its capacity. As might be expected, this remarkable feature has attracted a good deal of attention (*Journ. für Ornith.* 1861, p. 153; *Ibis*, 1862, p. 107; 1865, p. 143; *Proc. Zool. Soc.* 1865, p. 747; 1868, p. 741; 1869, p. 140; 1874, p. 471), and the researches of Professor Garrod, the latest investigator of the matter, shew that in an example of the Australian Bustard (*Otis australis*) examined by him there was, instead of a pouch or sack, simply a highly dilated œsophagus—the distention of which, at the bird's will, produced much the same appearance and effect as that of the undoubted sack found at times in the *O. tarda*.

The distribution of the Bustards is confined to the Old World—the bird so called in the Fur-Countries of North America, and thus giving its name to a lake, river, and cape, being the Canada Goose (*Bernicla canadensis*). In the Palæarctic Region we have the *O. tarda* already mentioned, extending from Spain to Mesopotamia at least, and from Scania to Morocco, as well as a smaller species, *O. tetrax*, which often occurs as a straggler in, but was never an inhabitant of, the British Islands. Two species, known indifferently by the name of Houbara (derived from the Arabic), frequent the more southern portions of the Region, and one of them, *O. macqueeni*, though having the more eastern range and reaching India, has several times occurred in North-western Europe, and once even in England. In the east of Siberia the place of *O. tarda* is taken by the nearly-allied, but apparently distinct, *O. dybowskii*, which would seem to occur also in Northern China. Africa is the chief stronghold of the family, nearly a score of well-marked species being peculiar to that continent, all of which have been by later systematists separated from the genus *Otis*. India, too, has three peculiar species, the smaller of which are there known as Floricans, and, like some of their African and one of their European cousins, are remarkable for the ornamental plumage they assume at the breeding-season. Neither in Madagascar nor in the Malay Archipelago is there any form of this family, but Australia possesses one large species already named. From Xenophon's days (*Anab.* i. 5) to our own, the flesh of Bustards has been esteemed as of the highest flavour. The Bustard has long been protected by the game-laws in Great Britain, but, as will have been seen, to little purpose. A few attempts have been made to reinstate it as a denizen of this country, but none on any scale that would ensure success. Many of the older authors considered the Bustards allied to the Ostrich, a most mistaken view, their affinity pointing apparently towards the Cranes in one direction and the Plovers in another. (A. N.)

BUSTO ARSIZIO, a town of Italy, in the province of Milan and district of Gallarate, about 19 miles N.W. of the city of Milan by rail. Its church of Santa Maria was planned by Bramante, and contains frescoes by Gaudenzio Ferrari; and St John's is also a noble building. Cotton is manufactured in the town, and the vine is cultivated in the neighbourhood. Population in 1870, 12,909.

BUTADES, wrongly called DIBUTADES, a Greek modeller in clay, whom fable describes as the first who modelled the human face in that material. The story is that his daughter, smitten with love for a youth at Corinth where they lived, drew upon the wall the outline of his shadow; and that upon this outline her father modelled a face of the youth in clay, and baked the model along with the clay tiles which it was his trade to make. This model was preserved in Corinth till Mummius sacked that town. This incident led Butades to ornament the ends of roof-tiles with human faces, a practice which is attested by numerous existing examples. He was a native of Sicyon, and probably lived about 600 B.C., at which date Corinth seems to have been a flourishing centre of working in clay.

BUTCHER-BIRD, a name frequently given to the Shrike family of Birds (*Laniadæ*), and particularly to the Great Grey Shrike (*Lanius excubitor*). See SHRIKE.

BUTE, COUNTY OF, is composed of three groups of islands which lie in the Firth of Clyde, betwixt the coasts of Ayrshire on the east, and Argyllshire on the north and west, viz., Bute, from which the county takes its name, with Inchmarnoch, a mile to westward; the two Cumbraes, less than a mile apart; and Arran, with the Holy Isle and Pladda islet, separated from each other by about a mile; the groups themselves being divided by channels from five to eight or ten miles in width. The area of the county is about 225 square miles. Before the application of steam to navigation and the introduction of the railway system, the voyage from Glasgow to Bute, Cumbrae, or Arran was always tedious and disagreeable, and sometimes fraught with peril, being performed in small and generally open sail-boats, often occupying days, and occasionally even weeks; now, by rail and steamer, the several islands can be reached in an hour and a half or two hours from Glasgow. In consequence of those facilities, and their acknowledged salubrity of climate, beauty and sublimity of scenery, and scientific and historic interest, the chief islands of Buteshire have for years attracted increasing numbers of tourists, artists, and men of science from all parts of the world. Buteshire, with the exception of some half-dozen small estates, is in the hands of four great proprietors. Arran, Holy Isle, and Pladda belong to the duke of Hamilton, and Bute and Inchmarnoch to the noble marquis who derives his title from the former. The Larger Cumbrae is the property of the earl of Glasgow and Lord Bute; and the Lesser Cumbrae, with its single farm, belongs to the earl of Eglinton. The proprietors of Bute and the Larger Cumbrae,—whose residences are respectively Mount Stuart, a few miles from Rothesay, and the Garrison, a handsome marine villa in the heart of Millport,—have given every encouragement to feuing and to all public improvements; consequently the beautiful watering-places in their vicinity have grown rapidly in population and importance. The census of 1871 gives the resident population of Buteshire at 16,977, 7623 males and 9354 females. Of these 10,094 were in Bute, 5259 in Arran, and 1624 in the Cumbraes. Since then the numbers are known to have largely increased, and in summer the population must be vastly greater. The electoral roll, which grows of course with the growth of the better class of feuars and householders, numbers at present 1150 voters. Prior to 1832 Buteshire, alternately with Caithness-shire, sent a member to Parliament,—Rothesay enjoying at the same time the privilege of sharing a representative with Ayr, Campbelton, Inveraray, and Irvine. On the passing of the Reform Bill of 1832, Rothesay was merged in the county, which since then has had a member to itself. Buteshire and Renfrewshire form one sheriffdom, with a sheriff-substitute resident in Rothesay, where are also situated the county buildings, including the court-house, prison, and public offices. The circuit courts are held at Inveraray.

BUTE, the most important of the several islands in the Firth of Clyde which constitute the county of the same name, is situated about 18 miles west of Greenock, and 40 by water from Glasgow. It is about 15 miles in length, extending from the picturesque "Kyles"—the narrow winding strait which separates the island on the north from the district of Cowal—to the Sound of Bute, about 8 miles in width, which separates it on the south from Arran. In breadth the island is unequal, from the deep indentations,

on both sides, of its numerous bays, but it averages from 3 to 5 miles, having on the east the Cumbraes 5 miles and the Ayrshire coast 8 miles off, and on the west Inchmarnoch (with an area of 675 acres) close at hand, and Ardrishaig, the highway to the Hebrides, within little more than two hours' sail of Rothesay.

The island has an area of 31,161 acres, two-thirds of which are arable, the remainder consisting of hill-pasture, plantings, moors, and sheets of water. Of the latter there are six. The largest, Loch Fad, 3 miles from Rothesay, is nearly 3 miles in length and about ¼ mile in breadth. From this copious source the Rothesay cotton-spinning mill, the first establishment of the sort erected in Scotland, derived by gravitation its propelling power. The mill continued in active operation, giving employment to some hundreds of people, until a few years ago, when, from the machinery having become antiquated and other causes, it ceased to be remunerative, and was closed. There are still two factories in the neighbourhood, with more modern machinery, for the weaving of cloth, but they are driven by steam-power. Loch Fad has a peculiar interest attaching to it, from having, on its western bank, the cottage built in 1827 by Edmund Kean, the great tragedian, who there found it "glorious through the loopholes of retreat to peep on such a world." The cottage, after Kean's death, fell into the hands of Mr J. B. Neilson, the ingenious inventor of "the hot-blast," and is now the property of Lord Bute. Notwithstanding the change of hands, the drawing-room is still retained precisely as Kean left it. Loch Ascog, within two miles of Rothesay, is less than Loch Fad, but quite as useful. It covers an area of 72 acres, and supplies the inhabitants of Rothesay with excellent water for domestic purposes. Quien Loch covers 54 acres, Greenan Loch 12, Loch Dhu 9, and Lochantarb 5 acres. The climate of Bute is mild, genial, and healthful, and is likened, not unfrequently, to that of Devonshire or of Montpellier. The mountains of Argyll and the peaks of Arran breaking the clouds as they pass from the Western Ocean, less rain falls on Bute than on any other part of the west coast; and the sea-breeze, generally blowing from the west and south, keeps the air cool in summer, and prevents snow from remaining or frost from continuing long in winter. The soil of Bute, for the most part light and gravelly, produces, under skilful treatment, excellent crops, particularly of potatoes, which, being readily disposed of by the acre while growing, are conveyed in barrels day by day to the Glasgow market. The farmers are a respectable class of men, intelligent, able-bodied, and long-lived. Coal has been found in the island, but of inferior quality and doubtful quantity. Supplies of this indispensable mineral are therefore brought from the fields of Ayrshire and Lanarkshire. Native limestone has been burned and used, but of late years it has given way almost entirely to Irish lime, which is extensively imported for building and manuring purposes. Of soft red sandstone, slate, and whinstone there is no lack, but they are chiefly used in the building of dykes and the gables and back walls of tenements, white sandstone and slates being largely imported for the front elevations and roofing of the better class of houses, which are now rapidly increasing in number. At Kilchattan there is an abundance of superior clay, and a thriving brick and tile work. Granite of a grey complexion, susceptible of a high polish, is also found at Kilchattan.

The islands of Bute and Inchmarnoch, excepting the small estates of Ascog and Ardbeg, the burgh lands, and one or two trifling holdings adjoining the town, belong to the marquis of Bute, whose favourite seat, Mount Stuart, is four miles from Rothesay on the eastern shore. The house, for which a much better site, commanding a view all round the island, might have been found, was begun in 1719 by the second earl, and finished after his death, in 1723, by Lady Bute, a daughter of the first duke of Argyll. It is a plain unpretentious mansion of moderate dimensions, recently much improved internally by the present marquis.

To the geologist, Bute offers little attraction as compared with Arran; yet the masses of conglomerate on the beach and forming the bold cliffs at Craigmore; the dykes of trap which crop up strikingly through the red sandstone and conglomerate at Ascog, and which may be traced shoreward towards Bogany Point and across the island to Ettrick Bay; and the vitrified forts at Dunnagoil (Garrochhead) and Island-bui (Kyles),—whether the result of volcanic action or only of beacon fires is doubtful,—will not be found unworthy of his notice. To the antiquary and the student of mediæval history Bute offers ample scope. The Druidical monuments, and the barrows, cairns, and cists are numerous throughout the island, as are also the remains of ancient chapels. For an account of Rothesay Castle and its deeply interesting historical associations, see ROTHESAY. Another object of interest is St Blane's chapel, picturesquely situated in a sheltered nook in the parish of Kingarth. It is believed to have been founded in the reign of Malcolm Canmore, towards the close of the 11th century, on the site of a much older edifice. This seems not improbable, as St Blane, who is said to have been a nephew of St Cattan, lived in the latter half of the 6th century. At all events, the names of both saints have been perpetuated in connection with the chapel and the neighbouring bay of Kilchattan. In the year 1204, Walter, Steward of Scotland, anxious "for the souls of kings David and Malcolm, and the souls of his own father and mother," as well as for "the salvation of himself and heirs," granted a charter conveying St Blane's, with all its valuable belongings in Bute, "to the monastery at Paisley, and the monks serving God therein." Time out of mind the chapel has been a ruin, surrounded by numerous graves of the forgotten dead; and having passed long ago from the custody of the church, it again belongs, with the lands attached to it, to a Stuart, Lord Bute.

There are still extant and habitable several old mansions in Bute, one or two of which may be pointed out. The most considerable is Kames Castle, three miles north-west of Rothesay. It stands in an extensive well-wooded park opposite the fine bay of the same name. It was long the residence of the Bannatyne family, a member of which, Lord Bannatyne, a judge of the Court of Session, projected the Highland Society in 1784, and founded the village of Port-Bannatyne, an abode of hardy fishermen, and now also a flourishing watering-place. Kames estate and castle are now the property of Lord Bute. Ascog House, about three miles from Rothesay in the opposite direction coastwise, is another old mansion in the Scottish baronial style. Standing on a richly-wooded height, it commands extensive views of the firth, and whether regarded from the road or the water contributes largely to enhance the beauty of perhaps the finest landscape in the island. The estate of Ascog belonged at one time to a branch of the Bute family. In 1815 it was purchased by the late Mr Robert Thom, C.E., of the Rothesay spinning-mill, who acquired celebrity by successfully engineering the introduction of water to the town of Greenock.

The island is divided into four parishes,—Rothesay, New Rothesay, Kingarth, and North Bute.

Rothesay, with its population of 7760 souls, has two Established churches, with a Gaelic chapel, two Free churches, with a Gaelic chapel, one United Presbyterian church, and three chapels—Episcopalian, Baptist, and Roman Catholic; while at Kingarth there are two

churches, Established and Free; at Ascog one, a Free church; and in North Bute an Established and a Free church. The school accommodation is likewise ample, both in town and country.

Touching the origin of the name of Bute, there is considerable doubt. It has been written Both, Bote, Boot, and Botis, and may thus be derived from "Both," which is the Irish for "a cell," St Brendan, an Irish abbot, having, it is said, caused a cell to be erected in the island in the 6th century; or it may have been derived from the old British words "Ey Budh," or the Gaelic words "Ey Bhiod," signifying the "island of corn," or "island of food," from its fertility as compared with the neighbouring islands and Highland districts. Although now all but obsolete, Gaelic was formerly the current language spoken. The Butemen in fighting times were called Brandanes, a distinction which they prized; and the numerous small landed proprietors, in virtue of a charter granted them in 1506 by James IV., took the title of baron, which became hereditary in their families. The title is now all but extinct, the lands which conferred it having passed by purchase from time to time, with one or two trifling exceptions, into possession of the Bute family. The descendants of the Brandanes were among the earliest to take part in the volunteer movement, by furnishing a couple of batteries to Lord Lorne's battalion of Argyll and Bute Artillery Volunteers, as well as a company to the Renfrewshire Rifles.

Great improvements have been recently made and are now (1876) in progress in Bute. The renovation, all but completed, of the grand old castle, and the formation of the esplanades of Rothesay,—together with the erection of an aquarium, and of an iron pier, where the accommodation was wanted, at the entrance to the bay, will tend, with other appreciated advantages, to give the island and shores of Bute a higher place than ever among the attractions of the Clyde. (R. H.)

BUTE, JOHN STUART, THIRD EARL OF (1713–1792), for a brief time prime minister of England, was born in 1713, and was educated at Eton. Horace Walpole, who was one of his contemporaries there, tells us that Bute "studied simples in the hedges about Twickenham." For many years he resided in the remote island of Bute, where he appears to have diligently studied mathematics, mechanics, and natural science. He married the daughter of Mr and the celebrated Lady Mary Wortley Montagu, an alliance which subsequently brought the large Wortley estates into his family. A mere accident introduced him at court; a shower of rain interrupted a cricket match at Cliefden, and led to his services being required by the Prince of Wales. He received a bedchamber appointment in the household of the prince. Prince Frederick died, however, next year, and Lord Bute lived in retirement. On the formation of a separate household for the princess and the young princes, he received the appointment of groom of the stole, somewhat to the dissatisfaction of the old king, George II., who gave him the gold key of office in an ungracious way. In the household of the Prince of Wales Lord Bute acquired great influence over the mind of the youthful heir of the throne and his mother. The scandal of the last century associated his name most intimately with that of the princess, but for this cruel and persistent rumour there appears to be no foundation either in contemporary literature or in the large inedited Bute MSS.

Lord Bute does not appear to have had much to do with the education of the future king and his brothers, which was chiefly left in episcopal hands. He took, however, some part in the direction of his studies, and is known to have read Blackstone's *Commentaries*, when still in MS., with him. He seems also to have inculcated him with the writings of Bolingbroke, whose theory was that a king should not only reign but govern, and who had sketched out the ideal of a patriot king. The constant language of the Princess Dowager, re-echoed by the groom of the stole, was "George, be king!" In 1760 George II. died, and the young king proceeded to put in practice the teachings he had received. This marked an important era in constitutional history. Then began the era of the "king's friends;" the royal will was to be supreme; the ministers were simply to act ministerially, giving expression to and carrying out the sovereign's pleasure. It is manifest that this doctrine weakened the responsibility of ministers and the authority of parliament, and invited dangers in the direction both of absolutism and of anarchy. Bute, however, was prepared to carry out a scheme very like Strafford's "Thorough" with zeal and energy. The day after the accession Bute was made a privy councillor. A little later he was made secretary of state. Afterwards he was made Knight of the Garter. The king told the ministers, "Lord Bute is my very good friend;" and the royal will was expressed through him. The extraordinary spectacle was witnessed, on the meeting of parliament, of a man with no political connection, who had never been in the cabinet, and who had never served in any ministerial office, being practically prime minister. What he was in reality he soon became in name. In the *Shelburne Correspondence* we find him asserting that there was nothing which he could not do. The ministers at the time of the accession, who both in the Eastern and the Western World were maintaining the war with France with the greatest glory and success, were William Pitt, the duke of Newcastle, and Mr Legge. The last, Mr Legge, was ignominiously dismissed. Pitt could not carry the support of the cabinet in his proposal to declare war against Spain, and therefore resigned, —a resignation which probably prevented a dismissal. Such insults were heaped upon the duke of Newcastle that, although he long clung to office, he was at last compelled to resign.

As premier, Bute showed considerable ability. Lord Mansfield said he never knew any man come to business so late who did it so well, and he proved an extremely good speaker. He also gave considerable patronage to literature and art. He had several distinct points of policy. He wished to close the era of war and make peace with France. He wished to sever the political connection between England and Hanover. He wished to humble the dominant Whig families, and to make the king supreme. In all these objects he was to a considerable extent successful. The popular feeling against the peace was intense. Still the minister had secured a large majority in the House of Commons; but although he had spoken much of purity of election, it is not to be denied that there had been extensive bribery in the elections. Confident of the royal support and a parliamentary majority, he seemed secure of a long lease of power.

After being premier for eleven months, to the astonishment of all, he suddenly resigned. He was unable to face the black tide of personal unpopularity which set in so heavily against him. Wilkes's publication of the *North Briton* had both expressed and intensified his unpopularity. He was in danger of being impeached; he was in danger of being torn in pieces by the mob. He went about disguised. He attempted to conciliate popularity by recalling Pitt to office; but Pitt would only return with his Whig friends, to which the king would not consent. Then Lord Bute's courage gave way. His own explanation was, "The ground I stand upon is so hollow that I am afraid, not only of falling myself, but of involving my royal master in my own ruin." But although he resigned office, his influence with the king was hardly impaired. It was the king's custom, at least for some time, to write a minute daily journal of

events and transmit it to Lord Bute. Both Grenville who succeeded him, and Rockingham, who succeeded Grenville, regarded him with the utmost jealousy. Grenville made it an absolute condition that Bute should retire from the presence and counsels of the young king. He retired to Luton; he afterwards travelled on the Continent under the name of Sir John Stuart He complained bitterly that he was not allowed "to enjoy that peace, that liberty, which is the birthright of the meanest Briton, but which has been long denied me."

The influence of Lord Bute over the king was great for a time, but it has been much exaggerated. After a few years it seems to have declined altogether. Both the king and Lord Bute soon disclaimed its existence, and there is no lack of corroboratory evidence But it was impossible to eradicate the notion that there was a back-stairs influence personified in Lord Bute. He was denounced in popular addresses before the king himself as a betrayer of the constitution, and mobs regularly broke his windows. Wilkes reviled him; Junius thundered against him. Lord Chatham declaimed against him as one behind the throne greater than the throne itself. For twenty years he was regarded with invincible hostility and suspicion, yet we find him complaining that he had not the influence of an alderman in obtaining a position for his son. Horace Walpole gives a curious account of an offer being made to Chatham shortly before his death of making him premier with a dukedom, he himself being a secretary of state. The facts are not well ascertained, but Lord Mountstuart, afterwards first marquis of Bute, wrote to assert upon his honour that his father, Lord Bute, assured him that he had not thought of coming into place again.

Lord Bute had purchased an estate at Luton in Bedfordshire, where Adams, the Scottish architect, had built him a magnificent residence. Here he formed an immense library, a superb collection of astronomical and philosophical instruments, and an admirable gallery of pictures, which are preserved in a large house appropriated to them in Warwick Square, London. On the summit of a plain Tuscan pillar in the grounds is an inscription in honour of his great friend and benefactress the Princess Dowager. He took great delight in architecture, and among other edifices built himself a marine villa on the edge of the cliff, in Hampshire, overlooking the Needles and the Isle of Wight. He is said to have been an admirable tutor and father to his children, and to have taken a greater pleasure in simple, natural delights than he could have found in courts. His death was occasioned through that intense love of natural science which had followed him through life. Seeing a new plant on the cliff he climbed towards it, and received a severe fall, which brought on an illness of which he died.

The eleven months' premiership, during which he was mayor of the palace, was a singular episode in his prolonged life,—a remarkable and unconstitutional experiment in politics which has never been repeated. Lord Bute possessed great virtues, great energy and ability, and was as able a premier as Newcastle, Grenville, or Rockingham. But the royal favouritism on which he relied proved the greatest bar to his political success, and has left a slur, exaggerated, but not altogether ill-deserved, on his memory. (F. A.)

BUTLER, ALBAN (1710–1773), a hagiologist, was born in Northampton in 1710. After completing his education at the Roman Catholic college at Douay, he was appointed professor of philosophy, and afterwards professor of divinity. In 1745 he travelled through France and Italy in company with the earl of Shrewsbury and some other gentlemen. On his return he was sent as member of a mission to Staffordshire, but was soon afterwards appointed chaplain to the duke of Norfolk, whose nephew he educated and accompanied on a Continental tour. After returning to England he was made president of the English college at St Omer's, where he remained till his death in 1773. His great work, the *Lives of the Saints*, was first published in 5 vols. 4to, 1745, and has passed through many editions. It exhibits great industry and research, with considerable power of expression, and is in all respects the best work of its kind in English literature.

BUTLER, CHARLES (1750–1832), nephew of the preceding, a miscellaneous writer, was born at London in 1750. He was educated at Douay, and in 1775 entered at Lincoln's Inn. He had considerable practice as a conveyancer, and after the passing of the Act Geo. III. c. 32 was called to the bar in 1791. In 1832 he received the silk gown, and was made a bencher of Lincoln's Inn. He died on the 2d June in the same year. His literary activity was enormous, and the number of his published works is very great. The most important of them are the *Reminiscences*, 1821–1827; *Horæ Biblicæ*, 1797, which has passed through several editions; *Horæ Juridicæ Subsecivæ*, 1804; *Book of the Roman Catholic Church*, which was directed against Southey and excited some controversy; lives of Erasmus, Grotius, and some others. He also edited his uncle's *Lives of the Saints* and Fearne's *Essay on Contingent Remainders*, and completed Hargrave's edition of *Coke upon Littleton*.

BUTLER, JAMES, DUKE OF ORMOND. See ORMOND.

BUTLER, JOSEPH, Bishop of Durham, one of the most distinguished writers on theology and ethics, and perhaps the man of greatest intellectual power in the English church during the 18th century, was born at Wantage, in Berkshire, on the 18th May 1692. His father was a respectable linen-draper of that town, who had retired from business some time before the birth of Joseph, his youngest son. The family belonged to the Presbyterian community, and it was their wish that young Butler should be educated for the ministry in that church. The boy was placed under the care of the Rev. Philip Barton, master of the grammar school at Wantage, and remained there for some years. He was then sent to a dissenting academy at Gloucester, which was afterward removed to Tewkesbury. The head-master was Mr Samuel Jones, a man of considerable abilities, several of whose pupils afterwards attained to eminence in the church. Butler's fellow-student and most intimate friend was Secker, who afterwards became archbishop of Canterbury.

While at this academy two important events occurred in Butler's life. He gradually became dissatisfied with the principles of Presbyterianism, and after much deliberation resolved to join the Church of England. In this resolution his father reluctantly acquiesced. About the same time he began to study with care Clarke's celebrated *Demonstration of the Being and Attributes of God*, which had been published a few years previously. With great modesty and secrecy Butler, who was then in his twenty-second year, wrote to the author propounding certain difficulties with regard to the proofs of the unity and omnipresence of the Divine Being. Clarke answered his unknown opponent with a gravity and care that showed his high opinion of the metaphysical acuteness displayed in the objections, and published the correspondence in later editions of the *Demonstration*. Butler acknowledged that Clarke's reply satisfied him on one of the points, and he subsequently gave his adhesion to the other.

In March 1714 he was entered at Oriel College, Oxford. Little is known of his life at the university; his most attached friend was Edward Talbot, son of Dr William Talbot, afterwards Bishop of Durham. In 1718, on the recommendation of Talbot and Clarke, he was nominated preacher at the Chapel of the Rolls, and continued there till 1726. In 1721 he had been appointed by Bishop

Talbot to the living of Houghton, and in 1725 his kind patron presented him to the wealthy rectory of Stanhope. In the following year he resigned his preachership at the Rolls, and published the first edition of the *Sermons*.

For nearly eight years he remained in perfect seclusion at Stanhope, and our information as to his general mode of life is exceedingly scanty. He was only remembered in the neighbourhood as a man much loved and respected, who used to ride a black pony very fast, and whose known benevolence was much practised upon by beggars. In 1733 he was made chaplain to Lord Chancellor Talbot, and in 1736 prebendary of Rochester. In the same year he was appointed clerk of the closet to Queen Caroline, and began to take part in the brilliant metaphysical society which she loved to gather round her. He met Berkeley frequently, but in his writings does not refer to him.

In 1736 appeared the *Analogy*, which at once took its place as the completest answer to the general deistical reasoners of the times, and as the best defence of revealed religion.

In 1736 Queen Caroline died; on her deathbed she recommended Butler to the favour of her husband. George, however, had not his consort's partiality for metaphysics, and seemed to think his obligation sufficiently discharged by appointing Butler in 1738 to the bishopric of Bristol, the poorest see in the kingdom. The severe but dignified letter in which Butler signified his acceptance of the preferment, must have shown him that the slight was felt and resented. Two years later the bishop was presented to the rich deanery of St Paul's, and in 1746 was made clerk of the closet to the king. In 1747 it is said the primacy was offered to Butler, who declined to accept it, saying that "it was too late for him to try to support a falling church." The story has not the best authority, and though the desponding tone of some of Butler's writings may give it colour, it is not in harmony with the rest of his life; for in 1750 he accepted the see of Durham, vacant by the death of Dr Edward Chandler. His charge to the clergy of the diocese, the only charge of his known to us, is a weighty and valuable address on the importance of external forms in religion. It gave rise to a most absurd rumour that the bishop had too great a leaning towards Romanism.

Of his life at Durham few incidents are known. He was very charitable, and expended large sums in building and decorating his church and residence. His private expenses were exceedingly small. He did not long survive his promotion. Shortly after the change to Durham his constitution began to break up, and he died on the 16th June 1752, at Bath, whither he had removed for his health. He was buried in the cathedral of Bristol, and over his grave a monument was erected in 1834, with an epitaph by Southey. According to his express orders, all his MSS. were burned after his death.

Butler was never married. His personal appearance has been sketched in a few lines by Hutchinson:—"He was of a most reverend aspect; his face thin and pale; but there was a divine placidness which inspired veneration, and expressed the most benevolent mind. His white hair hung gracefully on his shoulders, and his whole figure was patriarchal."

Underneath the meagre facts of his life, eked out by the few letters left by him or anecdotes told about him, there can be traced the outlines of a great but somewhat severe spirit. He was an earnest and deep-thinking Christian, melancholy by temperament, and grieved by what seemed to him the hopelessly irreligious condition of his age. His intellect was profound and comprehensive, thoroughly qualified to grapple with the deepest problems of metaphysics, but by natural preference occupying itself mainly with the practical and moral. Man's conduct in life, not his theory of the universe, was what interested him. His style has frequently been blamed for its obscurity and difficulty. These qualities, however, belong not so much to the form as to the matter of his works. The arguments are invariably compressed, and can never be taken individually. All are parts of one organic whole. Constant attention is thus required in order to grasp the relations of each isolated piece of reasoning. Above all, however, the special obscurity of the *Analogy* results from the difficulty of keeping constantly in mind the exact issue involved. Butler himself resolutely restricts his argument within the narrow limits prescribed for it, but it is difficult for any ordinary reader to keep this constantly in mind.

His great work, *The Analogy of Religion, Natural and Revealed, to the Course and Constitution of Nature*, cannot be adequately appreciated unless taken in connection with the circumstances of the period at which it appeared. It was intended as a defence against the great tide of deistical speculation, which in the apprehension of good men seemed likely to sweep away the restraints of religion, and make way for a general reign of licence. Deism, as a fact in English thought, takes its rise mainly from Locke, though traces of it are not wanting in Herbert of Cherbury. Whether or not the *Essay on the Human Understanding* should be held responsible for its results is a disputed question; but there can be no doubt that from the positions there laid down the general principles of the deists were drawn. Knowledge, in the strict sense of the word, had been restricted by Locke to the perception of the relations among ideas; reason was defined as the faculty which compared and compounded such ideas; and though with regard to God, faith was still admitted, the only part of the divine nature withdrawn from the province of knowledge was the inscrutable essence, which was equally unknown in the case of all real beings. The whole course of nature, including man's moral powers, was therefore subjected to reason; life must be regulated by reason. If, therefore, religion were to enter as a factor into the conduct of man, it must exhibit to reason the title deeds of its existence; Christianity must be reasonable. But with such a view of knowledge it was easy for the deists to make a successful attack upon at least one portion of the Christian scheme. A mystery by its very definition involved elements not capable of being represented in clear ideas; it was therefore unreasonable, and must be absolutely rejected. *Christianity not Mysterious* is the title of Toland's most famous work.

The course of their argument soon carried the deists farther. They were willing to grant the fact of God's existence; it was a dictate of reason. But they were not prepared to go beyond that, and the necessary deductions from it. The truths of natural religion thus took the form of inferences drawn from certain premises; they were displayed in a coherent, perfectly rational system. Revealed religion, on the other hand, was confessedly imperfect, contained things not in accordance with natural reason, inculcated duties on grounds of mere authority, was not universally and completely known, and must therefore be rejected. As Tindal puts it, "No religion can come from a Being of infinite wisdom and perfection but what is absolutely perfect. A religion absolutely perfect can admit of no alteration, and can be capable of no addition or diminution. If God has given mankind such a law, he must likewise have given them sufficient means of knowing it; he would otherwise have defeated his own intent in giving it, since a law, so far as it is unintelligible, ceases to be a law." It was against this whole tendency of thought that Butler directed his *Analogy*. The method and course of his argument will appear more plainly when it has been considered what were the premises on which he proceeded, and what the object he had in view.

Butler is a typical instance of the English philosophical mind. He will admit no speculative theory of things. To him the universe is no realization of intelligence, which is to be deciphered by human thought; it is a constitution or system, made up of individual facts, through which we thread our way slowly and inductively. Complete knowledge is impossible; nay, what we call knowledge of any part of the system is inherently imperfect. "We cannot have a thorough knowledge of any part without knowing the whole." So far as experience goes, "to us probability is the very guide of life." Reason is certainly to be accepted; it is our natural light, and the only faculty whereby we can judge of things. But it gives no completed system of knowledge, and in matters of fact affords only probable conclusions. In this emphatic declaration, that knowledge of the course of nature is merely probable, Butler is at one with Hume, and some of his expressions are exactly paralleled in the writings of the great sceptic, who was a most diligent student of the bishop's works. What can come nearer Hume's celebrated maxim,—"Anything may be the cause of anything else," than Butler's conclusion, "so that any one thing whatever may, for aught we know to the contrary, be a necessary condition to any other?"

It is this strong grasp of the imperfect character of our knowledge of nature and of the grounds for its limitation that makes Butler so formidable an opponent to his deistical contemporaries. He will permit no anticipations of nature, no *a priori* construction of experience. "The constitution of nature is as it is," and no system of abstract principles can be allowed to take its place. He is willing with Hume to take the course of experience as the basis of his reasoning, seeing that it is common ground for himself and his antagonists. In one essential respect, however, he goes beyond Hume. The course of nature is for him an unmeaning expression, unless it be referred to some author; and he therefore makes extensive use of the teleological method. This position is assumed throughout the treatise, and as against the deists with justice, for their whole argument rested upon the presupposition of the existence of God, the perfect Ruler of the world.

The premises, then, with which Butler starts are the existence of God, the known course of nature, and the necessary limitation of our knowledge. What does he wish to prove? It is not his intention *to prove God's perfect moral government over the world or the truth of religion.* His work is in no sense a philosophy of religion. His purpose is entirely defensive; he wishes to answer objections that have been brought against religion, and to examine certain difficulties that have been alleged as insuperable. And this is to be effected in the first place by showing that from the obscurities and inexplicabilities we meet with in nature we may reasonably expect to find similar difficulties in the scheme of religion. If difficulties be found in the course and constitution of nature, whose author is admitted to be God, surely the existence of similar difficulties in the plan of religion can be no valid objection against its truth and divine origin. That this is at least in great part Butler's object is plain from the slightest inspection of his work. It has seemed to many to be an unsatisfactory mode of arguing and but a poor defence of religion; and so much the author is willing to allow. But in the general course of his argument a somewhat wider issue appears. He seeks to show not only that the difficulties in the systems of natural and revealed religion have counterparts in nature, but also that the facts of nature, far from being adverse to the principles of religion, are a distinct ground for inferring their probable truth. He endeavours to show that the balance of probability is entirely in favour of the scheme of religion, that this probability is the natural conclusion from an inspection of nature, and that, as religion is a matter of practice, we are bound to adopt the course of action which is even probably the right one. If, we may imagine him saying, the precepts of religion are entirely analogous in their partial obscurity and apparent difficulty to the ordinary course of nature disclosed to us by experience, then it is credible that these precepts are true; not only can no objections be drawn against them from experience, but the balance of probability is in their favour. This mode of reasoning from what is known of nature to the probable truth of what is contained in religion is the celebrated method of analogy.

Although Butler's work is peculiarly one of those which ought not to be exhibited in outline, for its strength lies in the organic completeness with which the details are wrought into the whole argument, yet a summary of his results will throw more light on the method than any description can.

Keeping clearly in view his premises—the existence of God and the limited nature of knowledge,—Butler begins by inquiring into the fundamental prerequisite of all natural religion—the immortality of the soul. Evidently the stress of the whole question is here. Were man not immortal, religion would be of little value. Now, Butler does not attempt to prove the truth of the doctrine; that proof comes from another quarter. The only questions he asks are—Does experience forbid us to admit immortality as a possibility? Does experience furnish any probable reason for inferring that immortality is a fact? To the first of these a negative, to the second an affirmative answer is returned. All the analogies of our life here lead us to conclude that we shall continue to live after death; and neither from experience nor from the reason of the thing can any argument against the possibility of this be drawn. Immortality, then, is not unreasonable; it is probable. If, he continues, we are to live after death, it is of importance for us to consider on what our future state may depend; for we may be either happy or miserable. Now, whatever speculation may say as to God's purpose being necessarily universal benevolence, experience plainly shows us that our present happiness and misery depend upon our conduct, and are not distributed indiscriminately. Therefore no argument can be brought from experience against the possibility of our future happiness and misery likewise depending upon conduct. The whole analogy of nature is in favour of such a dispensation; it is therefore reasonable or probable. Further, we are not only under a government in which actions considered simply as such are rewarded and punished, but it is known from experience that virtue and vice are followed by their natural consequents—happiness and misery. And though the distribution of these rewards is not perfect, all hindrances are plainly temporary or accidental. It may therefore be concluded that the balance of probability is in favour of God's government in general being a moral scheme, where virtue and vice are respectively rewarded and punished. It need not be objected to the justice of this arrangement that men are sorely tempted, and may very easily be brought to neglect that on which their future welfare depends, for the very same holds good in nature. Experience shows man to be in a state of trial so far as regards the present; it cannot, therefore, be unreasonable to suppose that we are in a similar state as regards the future. Finally, it can surely never be advanced as an argument against the truth of religion that there are many things in it which we do not comprehend, when experience exhibits to us such a copious stock of incomprehensibilities in the ordinary course and constitution of nature.

It cannot have escaped observation, that in the foregoing course of argument the conclusion is invariably from experience of the present order of things to the reasonableness or probability of some other system—of a future state. The inference in all cases passes beyond the field of

experience; that it does so may be and has been advanced as a conclusive objection against it. The following sentences, from one of Hume's *Essays*, set forth this argument in a clear and forcible manner:—"What must a philosopher think of those vain reasoners who, instead of regarding the present scene as the sole object of their contemplation, so far reverse the whole course of nature, as to render this life merely a passage to something further? . . . . Whence, do you think, can such philosophers derive their idea of the gods? From their own conceit and imagination surely. For if they derive it from the present phenomena, it would never point to anything further, but must be exactly adjusted to them. That the divinity may possibly be endowed with attributes which we have never seen exerted, may be governed by principles of action which we cannot discover to be satisfied,—all this will freely be allowed. But still this is mere *possibility* and hypothesis. We never can have reason to infer any attributes or any principles of action in him, but so far as we know them to have been exerted and satisfied. . . . *Are there any marks of distributive justice in the world?* If you answer in the affirmative, I conclude that since justice here exerts itself, it is satisfied. If you reply in the negative, I conclude that you have then no reason to ascribe justice in our sense of it to the gods. If you hold a medium between affirmation and negation, by saying that the justice of the gods at present exerts itself in part, but not in its full extent, I answer, that you have no reason to give it any particular extent, but only so far as you see it *at present* exert itself." (*Works*, ed. 1854, iv. 161–2, *cf.* p. 160.) In short no argument from experience can ever carry us beyond experience itself. However well grounded this reasoning may be, it altogether misses the point at which Butler aimed, and is indeed a misconception of the nature of analogical argument. Butler never attempts to *prove* that a future life regulated according to the requirements of ethical law is a reality; he only desires to show that the conception of such a life is not irreconcilable with what we know of the course of nature, and that consequently it is *not unreasonable* to suppose that there is such a life. Hume, it will be observed, readily grants as much, though he hints at a formidable difficulty which the plan of the *Analogy* prevented Butler from facing, the proof of the existence of God. Butler seems willing to rest satisfied with his opponents' admission that the being of God is proved by reason, but it would be hard to discover how, upon his own conception of the nature and limits of reason, such a proof could ever be given. It has been said that it is no flaw in Butler's argument that he has left atheism as a possible mode of viewing the universe, because his work was not directed against the atheists. It is, however, in some degree a defect; for his defence of religion against the deists rests on a view of reason which would for ever preclude a demonstrative proof of God's existence.

If, however, his premises be granted, and the narrow issue kept in view, the argument may be admitted as perfectly satisfactory. From what we know of the present order of things, it is not unreasonable to suppose that there will be a future state of rewards and punishments, distributed according to ethical law. When the argument from analogy seems to go beyond this, a peculiar difficulty starts up. Let it be granted that our happiness and misery in this life depend upon our conduct,—are, in fact, the rewards and punishments attached by God to certain modes of action, the natural conclusion from analogy would seem to be that our future happiness or the reverse will probably depend upon our actions in the future state. Butler, on the other hand, seeks to show that analogy leads us to believe that our future state will depend upon our present conduct. His argument, that the punishment of an imprudent act often follows after a long interval may be admitted, but does not advance a single step towards the conclusion that imprudent acts will be punished hereafter. So, too, with the attempt to show that from the analogy of the present life we may not unreasonably infer that virtue and vice will receive their respective rewards and punishments hereafter; it may be admitted that virtuous and vicious acts are naturally looked upon as objects of reward or punishment, and treated accordingly, but we may refuse to allow the argument to go further, and to infer a perfect distribution of justice dependent upon our conduct here. Butler could strengthen his argument only by bringing forward prominently the absolute requirements of the ethical consciousness, in which case he would have approximated to Kant's position with regard to this very problem. That he did not do so is, perhaps, due to his strong desire to use only such premises as his adversaries the deists were willing to allow.

As against the deists, however, he may be allowed to have made out his point, that the substantial doctrines of natural religion are not opposed to reason and experience, and may be looked upon as credible. The positive proof of them is to be found in revealed religion, which has disclosed to us not only these truths, but also a further scheme not discoverable by the natural light. Here, again, Butler joins issue with his opponents. Revealed religion had been declared to be nothing but a republication of the truths of natural religion (Tindal, *Christianity as Old as the Creation*), and all revelation had been objected to as impossible. To show that such objections are invalid, and that a revelation is at least not impossible, Butler makes use mainly of his doctrine of human ignorance. Revelation had been rejected because it lay altogether beyond the sphere of reason and could not therefore be grasped by human intelligence. But the same is true of nature; there are in the ordinary course of things inexplicabilities; indeed we may be said with truth to know nothing, for there is no medium between perfect and completed comprehension of the whole system of things, which we manifestly have not, and mere faith grounded on probability. Is it unreasonable to suppose that in a revealed system there should be the same superiority to our intelligence? If we cannot explain or foretell by reason what the exact course of events in nature will be, is it to be expected that we can do so with regard to the wider scheme of God's revealed providence? Is it not probable that there will be many things not explicable by us? From our experience of the course of nature it would appear that no argument can be brought against the possibility of a revelation. Further, though it is the province of reason to test this revealed system, and though it be granted that, should it contain anything immoral, it must be rejected, yet a careful examination of the particulars will show that there is no incomprehensibility or difficulty in them which has not a counterpart in nature. The whole scheme of revealed principles is, therefore, not unreasonable, and the analogy of nature and natural religion would lead us to infer its truth. If, finally, it be asked, how a system professing to be revealed can substantiate its claim, the answer is, by means of the historical evidences, such as miracles and fulfilment of prophecy.

It would be unfair to Butler's argument to demand from it answers to problems which had not in his time arisen, and to which, even if they had then existed, the plan of his work would not have extended. Yet it is at least important to ask how far, and in what sense, the *Analogy* can be regarded as a positive and valuable contribution to theology. What that work has done is to prove to the consistent deist that no objections can be drawn from reason or experience against natural or revealed religion, and, consequently, that the things objected to are not incredible

and may be proved by external evidence. But the deism of the 17th century is a phase of thought that has no living reality now, and the whole aspect of the religious problem has been completely changed. To a generation that has been moulded by the philosophy of Kant and Hegel, and by the historical criticism of Strauss and the later German theology, the argument of the *Analogy* cannot but appear to lie quite outside the field of controversy. To Butler the Christian religion, and by that he meant the orthodox Church of England system, was a moral scheme revealed by a special act of the divine providence, the truth of which was to be judged by the ordinary canons of evidence. The whole stood or fell on historical grounds. A speculative construction of religion was a thing abhorrent to him, a thing of which he seems to have thought the human mind naturally incapable. The religious consciousness does not receive from him the slightest consideration, whereas it is with its nature and functions that the scientific theology of the present time is almost entirely occupied. The *Analogy*, it would appear, has and can have but little influence on the present state of theology; it was not a book for all time, but was limited to the controversies and questions of the period at which it appeared.

Throughout the whole of the *Analogy*, it is manifest that the interest which lay closest to Butler's heart was the ethical. His whole cast of thinking was practical. The moral nature of man, his conduct in life, is that on account of which alone an inquiry into religion is of importance. The systematic account of this moral nature is to be found in the famous *Sermons preached at the Chapel of the Rolls*, especially in the first three. In these sermons Butler has made substantial contributions to ethical science, and it may be said with confidence, that in their own department nothing superior in value appeared during the long interval between Aristotle and Kant. To both of these great thinkers he has certain analogies. He resembles the first in his method of investigating the end which human nature is intended to realize; he reminds of the other by the consistency with which he upholds the absolute supremacy of moral law.

In his ethics, as in his theology, Butler had constantly in view a certain class of adversaries, consisting partly of the philosophic few, partly of the fashionably-educated many, who all participated in one common mode of thinking. The key-note of this tendency had been struck by Hobbes, in whose philosophy man was regarded as a mere sensitive machine, moved solely by pleasures and pains. Human nature had come to be looked upon as essentially selfish; disinterested actions were sneered at as impossibilities by the many, and were explained away into modifications of selfishness by the scientific moralists. Cudworth and Clarke, it is true, had tried to place ethics on a nobler footing, but their speculations had been of the abstract kind, which was always distasteful to Butler. They were not practical enough, were not sufficiently "applicable to the several particular relations and circumstances of life." He desired to base ethical law not on abstract theory, but on the actual facts of human nature.

The fundamental view of things from which he starts in his inquiry may be called the teleological. "Every work, both of nature and art, is a system; and as every particular thing both natural and artificial is for some use or purpose out of or beyond itself, one may add to what has been already brought into the idea of a system its conduciveness to this one or more ends." Ultimately this view of nature, as the sphere of the realization of final causes, rests on a theological basis; but Butler does not introduce prominently into his ethics the specifically theological groundwork, and may be thought willing to ground his principle on experience. The ethical question then is, as with Aristotle, what is the τέλος of man? He is placed in the world with many courses of action open to him. What is that line of activity which is correspondent to, or is the realization of, his true nature? The answer to this question is to be obtained by an analysis of the facts of human nature, whence, Butler thinks, "it will as fully appear that this our nature, *i.e.*, constitution, is adapted to virtue, as from the idea of a watch it appears that its nature, *i.e.*, constitution or system, is adapted to measure time." Such analysis had been already attempted by Hobbes, and the result he came to was that man naturally is adapted only for a life of selfishness,—his end is the procuring of pleasure and the avoidance of pain. A closer examination, however, shows that this at least is false. The truth of the counter propositions, that man is φύσει πολιτικός, naturally social, and that the full development of his being is impossible apart from society, becomes manifest on the slightest examination of the facts. For while self-love plays a most important part in the human economy, there is no less evidently a natural principle of benevolence, prompting actions which have for their end the good of others. Moreover, among the particular passions, appetites, and desires there are some whose tendency is as clearly towards the general good as that of others is towards our own satisfaction. Finally, that principle in man which reflects upon actions and the springs of actions, which approves some and disapproves others, unmistakably sets the stamp of its approbation upon conduct that tends towards the general good. It is clear, therefore, that we were made for society; man is ζῶον πολιτικόν, and from this point of view the sum of practical morals might be given in Butler's own words,—"that mankind is a community, that we all stand in a relation to each other, that there is a public end and interest of society, which each particular is obliged to promote." But deeper questions remain.

The threefold division into passions and affections, self-love and benevolence, and conscience, is Butler's celebrated analysis of human nature. In the handling of the several parts he shows remarkable psychological power, and succeeds in obviating many of the difficulties drawn from the principles of the selfish theory of ethics. He is especially concerned to show that self-love and benevolence are in no sense opposed to one another. This he does by examining the function of self-love and the relation it bears to the passions. The special desires or affections are the expressions of wants in our nature which are to be satisfied by the possession of definite things. The objects of the desires are therefore the things naturally adapted to satisfy them, and not the pleasure which is the accompaniment of satisfaction. The passions tend towards their objects as ultimate ends, and are consequently unselfish or disinterested. On the other hand, self-love aims at procuring happiness for the individual; and happiness means the general satisfaction of desires. Self-love is therefore distinct from the particular desires, but is completely dependent on them. Its end is the attainment of pleasure, and it desires external things only as means towards this. In itself it has no actual content; it only directs the particular passions towards their ends, and frequently, by fixing its attention too much upon its own goal, personal happiness, is in danger of defeating its own endeavours. Self-love is therefore distinct from and in no way opposed to the particular affections which are themselves disinterested. Just as little opposition is there between self-love and disinterested benevolence. An affection which finds its gratification in some external object and rests in it as a final end, is in no sense opposed to self-love. This is one of the most important parts of Butler's ethical psychology.

Up to this point he has merely analyzed the various parts of human nature, and has pointed out the course of action corresponding to each. But in a system or organism the parts do not exist for themselves but for the whole. The idea of human nature is not completely expressed by saying that it consists of reason and the several passions. "Whoever thinks it worth while to consider this matter thoroughly should begin by stating to himself exactly the idea of a system, economy, or constitution of any particular nature; and he will, I suppose, find that it is one or a whole, made up of several parts, but yet that the several parts, even considered as a whole, do not complete the idea, unless in the notion of a whole you include the relations and respects which these parts have to each other." This fruitful conception of man's ethical nature as an organic unity Butler owes directly to Shaftesbury and indirectly to Aristotle; it is the strength and clearness with which he has grasped it that gives peculiar value to his system.

The special relation among the parts of our nature to which Butler alludes is the subordination of the particular passions to the universal principle of reflection or conscience. This relation is the peculiarity, the *cross*, of man; and when it is said that virtue consists in following nature, we mean that it consists in pursuing the course of conduct dictated by this superior faculty. Man's function is not fulfilled by obeying the passions, or even cool self-love, but by obeying conscience. That conscience has a natural supremacy, that it is superior in kind, is evident from the part it plays in the moral constitution. We judge a man to have acted wrongly, *i.e.*, unnaturally, when he allows the gratification of a passion to injure his happiness, *i.e.*, when he acts in accordance with passion and against self-love. It would be impossible to pass this judgment if self-love were not regarded as superior in kind to the passions, and this superiority results from the fact that it is the peculiar province of self-love to take a view of the several passions and decide as to their relative importance. But there is in man a faculty which takes into consideration all the springs of action, including self-love, and passes judgment upon them, approving some and condemning others. From its very nature this faculty is supreme in authority, if not in power; it reflects upon all the other active powers, and pronounces absolutely upon their moral quality. Superintendency and authority are constituent parts of its very idea. We are under obligation to obey the law revealed in the judgments of this faculty, for it is the law of our nature. And to this a religious sanction may be added, for "consciousness of a rule or guide of action, in creatures capable of considering it as given them by their Maker, not only raises immediately a sense of duty, but also a sense of security in following it, and a sense of danger in deviating from it." Virtue then consists in following the true law of our nature, that is, conscience. Butler, however, is by no means very explicit in his analysis of the functions to be ascribed to conscience. He calls it the Principle of Reflexion, the Reflex Principle of Approbation, and assigns to it as its province the motives or propensions to action. It takes a view of these, approves or disapproves, impels to or restrains from action. But at times he uses language that almost compels one to attribute to him the popular view of conscience as passing its judgments with unerring certainty on individual acts. Indeed his theory is weakest exactly at the point where the real difficulty begins. We get from him no satisfactory answer to the inquiry, What course of action is approved by conscience? Everyone, he seems to think, knows what virtue is, and a philosophy of ethics is complete if it can be shown that such a course of action harmonizes with human nature. When pressed still further, he points to justice, veracity, and the common good as comprehensive ethical ends. His whole view of the moral government led him to look upon human nature and virtue as connected by a sort of pre-established harmony. His ethical principle has in it no possibility of development into a system of actual duties; it has no content. Even on the formal side it is a little difficult to see what part conscience plays. It seems merely to set the stamp of its approbation on certain courses of action to which we are led by the various passions and affections; it has in itself no originating power. How or why it approves of some and not of others is left unexplained. Butler's moral theory, like those of his English contemporaries and successors, is defective from not perceiving that the notion of duty can only have real significance when connected with the will or practical reason, and that only in reason which wills itself have we a principle capable of development into an ethical system.

It has frequently been made the ground of objection to Butler's philosophy of man's moral nature that he did not carry his analysis far enough, and that he accepted as ultimate facts what are really compounded of simpler elements. His distinction between self-love and the passions has in particular been rejected on the plea that the end of appetite or desire is not the object suited to satisfy it, but pleasure, or at least the removal of uneasiness. This last, however, is fairly included under Butler's expression, "gratification of the passions." The removal of uneasiness no doubt results in pleasure, but it is not the pleasure that removes the uneasiness. What is really sought is the object that will satisfy us, that will fill up the want in our existence, and with which we, so to speak, identify ourselves. With regard to the general objection, even were it granted that self-love and benevolence are developments from the passions, the relations between them would none the less hold good. Self-love is not superior to the passions, because it has been originally created their superior, but because under the sphere of its inspection and decision the particular desires are included; it stands above them because they form the objects upon which it works. Further, growth or development, deeply considered, does not invalidate authority or superiority in kind. The ethical consciousness, like all other parts of our nature, grows; it is only by degrees and slowly that man comes to the full recognition of the reason that lies in him and forms his true personality. He is moral at first only δύναμει, and the varying conditions of experience are requisite in order to afford the means of development from this mere potentiality. The customary observances and legal precepts, in which the common ethical consciousness of humanity has given expression to itself, are being continually tested by comparison with the formal requirements of the inner law of duty, and change gradually as they are found at various epochs to be imperfect realizations of reason. The ultimate goal of all such progress is that state of ethical observance in which rights and duties come to be recognized as the outcome of human personality, and the realization of true freedom.

Bartlett, *Memoirs of Butler*, 1839. The best edition of Butler's works is that in 2 vols., Oxford. Editions of the *Analogy* are very numerous; that by Fitzgerald, 1849, contains a valuable Life and Notes. Whewell has published an edition of the *Three Sermons*, with Introduction. The analyses of the *Analogy* by Duke (1847) and Wilkinson (1847), Chalmers's *Prelections* (posthumous works, ix.), Napier's *Lectures*, (1864), and Swainson's *Handbook* may be consulted with advantage. For the history of the religious works contemporary with the *Analogy*, see Lechler, *Ges. d. Engl. Deismus;* Pattison, in *Essays and Reviews;* Hunt's *Religious Thought in England*, vols. ii. and iii.; A. S. Farrar, *Critical History of Free Thought*. For Butler's ethics see Mackintosh, Whewell, and Jouffroy. It is quite surprising that German historians of ethics should ignore Butler. Feuerlein, Fichte, Wuttke, and Trendelenburg totally omit mention of his name; Vorländer, in his *Ges. d. Phil. Moral, Rechts- und Staats-lehre d. Engländer u. Franzosen*, devotes three pages to Butler and fifteen to Bolingbroke. (R. AD.)

BUTLER, SAMUEL (1612–1680), whose name appears to have been spelt Boteler in official documents to the end of his life, was born at Strensham on the Avon in Worcestershire. He was baptized on the 8th of February 1612. His father, who was of the same name and was then churchwarden, is variously represented as a substantial farmer (owning a small freehold, and leasing from Sir William Russel a considerable farm valued at £300 a year), and as "a man of but slender fortune," who was barely able to educate his son at a free school. The author of *Hudibras* was apparently educated at the college (or cathedral) school, Worcester, and the house in which he was born was pulled down (being considered incapable of repair) about 1873. Hardly any other particulars of his youth are recorded, and his later education (if he received any) is equally uncertain. He has been loosely asserted (as is the case with many other distinguished persons of his century) to have studied at both Cambridge and Oxford, but the balance of testimony seems to be against his having belonged to either university. The time between the completion of his education (*circa* 1630) and the Restoration, a period of fully thirty years, appears to have been spent by him in three different households, with Mr Jefferies of Earl's Croome in Worcestershire, with the countess of Kent at Wrest in Bedfordshire, and with Sir Samuel Luke at Woodend or Cople Hoo in the same county. He served Mr Jefferies in the capacity of justice's clerk, and is supposed to have thus laid the foundation of his remarkable knowledge of law and law terms. He also employed himself at Earl's Croome in general study, and particularly in painting, which he is said to have thought of adopting as a profession. It is probable, however, that art has not lost by his change of mind, for, according to one of his editors, in 1774 his pictures "served to stop windows and save the tax; indeed they were not fit for much else." At Wrest, where he is said to have been gentleman to the countess, he pursued his studies in painting, drawing, and music; probably, also, in other directions, for Wrest contained a good library. Here he met and worked for Selden. But his third sojourn, that at Cople Hoo, was not only apparently the longest, but also much the most important in its effects on his career and works.

We are nowhere informed, nor is it at all clear, in what capacity Butler served Sir Samuel Luke, or how one who was not only in temper and sympathies, but also from early associations, a decided royalist, came to reside in the house of a noted Puritan and Parliament man. In the family of this "valiant Mamaluke," who, whether he was or was not the original of *Hudibras*, was certainly a rigid Presbyterian, "a colonel in the army of the Parliament, scoutmaster-general for Bedfordshire and governor of Newport Pagnell," Butler must have had the most abundant opportunities of studying from the life those who were to be the victims of his great future satire. But we know not how long he held his situation (whatever it was) under the knight of Cople, and we hear nothing positive of him till the Restoration, immediately after which he was appointed secretary to Lord Carbery (then President of Wales) and steward of Ludlow Castle. Contradictory documents exist respecting his tenure of the latter office, one speaking of him as "late steward" in January 1662, the other (a protection against arrest) addressed to him as steward in September 1667. About this time he married a Mrs Herbert, according to Aubrey a widow with a good jointure, on whose means he lived comfortably. Aubrey knew him well and could hardly be wrong on such a point, especially as his testimony as to Butler's living in comparative comfort is confirmed by another authority to be afterwards mentioned. It should, however, be observed that other accounts state that Mrs Herbert's fortune was lost through bad securities. Late in 1662 the first part of *Hudibras* was published. On the 26th of December Pepys bought it, and though neither then nor afterwards could he see the wit of it, he repeatedly testifies to its extraordinary popularity. This popularity is most clearly proved by the issue of a pirated edition within a month, and by the appearance of a spurious second part within the year. This latter compliment (which it will be remembered was also paid to Butler's spiritual ancestor Cervantes) determined the poet to bring out the second part, which was licensed on November 7, 1663, and which if possible exceeded the first in popularity. From this time till 1678, the date of the publication of the third part, we hear nothing certain and hardly anything at all of Butler. He appears at some period to have visited France. He is said to have received a gift of £300 from Charles II., and to have been secretary to Buckingham when the latter was Chancellor of the University of Cambridge. Most of his biographers, in their eagerness to prove the ill-treatment which Butler is supposed to have received, disbelieve both these stories, perhaps without sufficient reason. It must be allowed that it is scarcely a valid argument that Butler, if he had been secretary to Buckingham, would not have spoken so severely of that nobleman in his *Characters* (*Remains*, 1759), when it is remembered that he satirized Sir Samuel Luke, to whom he held nearly the same relation, with certainly equal virulence. Two years after the publication of the third part he died (September 25, 1680), and was buried by his friend Mr William Longueville (a bencher of the Middle Temple) in the churchyard of St Paul's, Covent Garden. He was, we are told, "of a leonine-coloured hair, sanguine, choleric, middle-sized, strong." Portraits exist at Oxford and elsewhere which represent him as somewhat hard-featured. Two personal anecdotes, and perhaps two only, are recorded of him. One is the well-known story which tells how Wycherly laboured hard to secure for the neglected poet the patronage of Buckingham, how an interview was at last arranged, from which the duke was, alas! called off by the passage of "a brace of ladies," and how the opportunity was lost. The other bears suspicious marks of having been made up as setting for a witticism of Lord Dorset's. Dorset, it seems, was anxious to know the author of *Hudibras*, and prevailed on a common friend to bring him to a tavern. At the first bottle Butler was quiet and reserved, at the second full of wit and spirits, at the third dull and stupid,—upon which Dorset's comment was that Butler was "like a nine-pin, little at both ends, but great in the middle." Of these stories it may be said, as of most such, that they may be true and cannot be proved to be false.

Of the neglect of Butler by the Court something must be said. It must be remembered that the complaints on the subject supposed to have been uttered by the poet all occur in the spurious posthumous works, that men of letters have been at all times but too prone to complain of lack of patronage (a fact which makes it probable that Dryden, Otway, Oldham, &c., in alluding to Butler, spoke as the proverb of that day went, "one word for him and two for themselves"), that the actual service rendered by Butler was rendered when the day was already won, and that the pathetic stories of the poet starving and dying in want are contradicted by the best authority—Mr C. Longueville (son of the poet's friend)—who asserted that Butler, though often disappointed, was never reduced to anything like want or beggary, and did not die in any person's debt. But the most significant story on the subject is Aubrey's, that "he might have had preferments at first, but would not accept any but very good, and so got none."

Three monuments have been at different times and places erected to the poet's memory,—the first in 1721 by

Alderman-Barber in Westminster Abbey. This was the occasion of some rather misplaced wit from Pope and others. In 1786 a tablet was placed in St Paul's, Covent Garden, by some inhabitants of that parish. This was destroyed in 1845. Some thirty or forty years ago another was set up at Strensham by a Mr Taylor of that place. Perhaps the happiest epitaph on him is one by Dennis, which (borrowing, indeed, its most striking expression from Cowley) sets forth that Butler "was a whole species of poets in one."

Butler's published works during his life consisted of the three parts of *Hudibras* (the second and third were republished together in 1674, with notes by the author); of an *Ode on Duval* (the famous highwayman); and of two pamphlets attributed to Prynne. In 1715 three volumes, entitled *Posthumous Works of Mr S. Butler*, were published with great success. Their contents, however, are all spurious except one or two short pieces. The poet's papers remained in the hands of his friend Mr Longueville, and were not published till 1759, when Mr Thyer, librarian at Manchester, edited two volumes of verse and prose under the title of *Genuine Remains*. The most remarkable of the prose writings are characters of the kind popular in the 17th century, and partaking largely of the faults usual in such pieces. To this some additional fragments were added in 1822; a fragment of a tragedy on Nero is also spoken of. In 1726 Hogarth executed some illustrations to *Hudibras*, which are among his earliest but not, perhaps, happiest productions. In 1744 Dr Zachary Grey published an edition of *Hudibras*, which has been repeatedly reprinted, and has formed (with that of Nash in 1793) the basis of all subsequent editions. It contains an enormous mass of notes, displaying little critical or literary power, but abounding in curious information. A worthy edition is still to seek; but that of the late Mr R. Bell is convenient, and supplies much information, which is generally accurate. Mr Bohn's (of *Hudibras* only) is also useful. Butler's lesser works would of themselves fairly sustain, though perhaps they would hardly create, a great reputation. Abundance of happy thought, of ingenious expression, and of vigorous verse, may be found in the *Miscellaneous Thoughts*, the *Ode on Duval*, and the *Satires* on the Royal Society (*The Elephant in the Moon*) and on *Critics*. But the splendour of *Hudibras* has somewhat paled their fire.

Hudibras itself, though probably quoted as often as ever, has perhaps dropped into the class of books which are more quoted than talked of, and more talked of than read. In reading it, it is of the utmost importance to comprehend clearly and to bear constantly in mind the purpose of the author in composing it. This purpose is evidently not artistic but polemic, to show in the most unmistakable characters the vileness and folly of the anti-royalist party. Anything like a regular plot—the absence of which has often been deplored or excused—would have been for this end not merely a superfluity but a mistake, as likely to divert the attention and perhaps even enlist some sympathy for the heroes. Anything like regular character-drawing would have been equally unnecessary and dangerous—for to represent anything but monsters, some alleviating strokes must have been introduced. The problem, therefore, was to produce characters just sufficiently unlike lay-figures to excite and maintain a moderate interest, and to set them in motion by dint of a few incidents not absolutely unconnected,—meanwhile to subject the principles and manners of which these characters were the incarnation to ceaseless satire and raillery. The triumphant solution of the problem is undeniable, when it has once been enunciated and understood. Upon a canvas thus prepared and outlined, Butler has embroidered a collection of flowers of wit, which only the utmost fertility or imagination could devise, and the utmost patience of industry elaborate. In the union of these two qualities he is certainly without a parallel, and their combination has produced a work which is unique. The poem is of considerable length, extending to more than ten thousand verses, yet Hazlitt hardly exaggerates when he says that "half the lines are got by heart;" indeed a diligent student of later English literature has read great part of *Hudibras* though he may never have opened its pages. The tableaux or situations, though few and simple in construction, are ludicrous enough. The knight and squire setting forth on their journey; the routing of the bear-baiters; the disastrous renewal of the contest; Hudibras and Ralph in the stocks; the lady's release and conditional acceptance of the unlucky knight; the latter's deliberations on the means of eluding his vow; the Skimmington; the visit to Sidrophel, the astrologer; the attempt to cajole the lady, with its woeful consequences; the consultation with the lawyer, and the immortal pair of letters to which this gives rise complete the argument of the whole poem. But the story is as nothing; throughout we have little really kept before us but the sordid vices of the sectaries, their hypocrisy, their churlish ungraciousness, their greed of money and authority, their fast and loose morality, their inordinate pride. The extraordinary felicity of the means taken to place all these things in the most ridiculous light has never been questioned. The doggrel metre, never heavy or coarse, but framed so as to be the very voice of mocking laughter, the astounding similes and disparates, the rhymes which seem to chuckle and to sneer of themselves, the wonderful learning with which the abuse of learning is rebuked, the subtlety with which subtle casuistry is set at nought can never be missed. Keys like those of L'Estrange are therefore of little use. It signifies nothing whether Hudibras was Sir Samuel Luke of Bedfordshire or Sir Henry Rosewell of Devonshire, still less whether Ralph's name in the flesh was Robinson or Pendle, least of all that Orsin was perhaps Mr Gosling, or Trulla possibly Miss Spencer. Butler was probably as little indebted to mere copying for his characters as for his ideas and style. These latter are in the highest degree original. The first notion of the book, and only the first notion, Butler undoubtedly received from *Don Quixote*. His obligations to the *Satyre Ménippée* have been noticed by Voltaire, and though English writers have sometimes ignored or questioned them, are not to be doubted by any student of the two books. The art (perhaps the most terrible of all the weapons of satire) of making characters without any great violation of probability represent themselves in the most atrocious and despicable light was never perhaps possessed in perfection except by Pithou and his colleagues and by Butler Against these great merits some defects must certainly be set. As a whole, the poem is no doubt tedious, if only on account of the very blaze of wit, which at length almost wearies us by its ceaseless demands on our attention. It should, however, be remembered that it was originally issued in parts, and therefore (it may be supposed) intended to be read in parts, for there can be little doubt that the second part was written before the first was published. A more real defect, but one which Butler shares with all his contemporaries from Jonson downwards, is the tendency to delineate humours instead of characters, and to draw from the outside rather than from within. This also may be partially palliated by some remarks made above.

Attempts have been made without much success to trace the manner and versification of *Hudibras*, especially in Cleveland and in the *Musarum Deliciæ* (lately reprinted) of Sir John Mennis (Pepys's Minnes) and Dr Smith. But if it had few ancestors it had an abundant offspring. A

list of seventeen direct imitations of *Hudibras* in the course of a century was given in the *Retrospective Review*, and may be found in Mitford's *Butler*. Portions of it have been at different times translated into Latin with no great success. Complete translations of considerable excellence have been made into French by John Townley (London, 1757, 3 vols.), and into German by D. W. Soltau (Riga, 1787); specimens of both may be found in Bell's edition. Voltaire tried his hand at a compressed version, but not happily. (G. SA.)

BUTLER, WILLIAM ARCHER (1814–1848), a brilliant writer on theology and the history of philosophy, was born at Annerville, near Clonmel, probably in 1814. His father was a Protestant, his mother a Roman Catholic, and he was brought up in the Romish faith. At the age of nine he was sent to Clonmel school, where he distinguished himself not so much by rigid attention to his class work as by general brilliancy and power. Even when a boy he was strongly drawn towards the imaginative and poetical, and some of his early verses show an astonishing precocity. After leaving Clonmel school he entered Trinity College, Dublin. Two years before he had joined the Protestant church. His career at college was remarkably brilliant. The studies to which he specially devoted himself were the literary and metaphysical; and he was particularly noted for the extreme beauty of his style, both in speaking and in written exercises. In 1834 he gained the ethical moderatorship, newly instituted by Provost Lloyd, and continued in residence at college, pursuing his favourite studies. Many papers were about this time contributed by him to the *Dublin University Magazine*; it is to be regretted that these have not been collected. In 1837 he made up his mind to enter the church, and in the same year he was elected to the professorship of moral philosophy, specially founded for him through the exertions of Provost Lloyd. About the same time he was presented to the prebend of Clondehorka, in Donegal, and resided there when not called by his professorial duties to Dublin. In 1842 he was promoted to the rectory of Raymoghy. His lectures and his sermons were equally admired for their strength of thought and richly imaginative style. In 1845 appeared in the *Irish Ecclesiastical Journal* his *Letters on Development*, written under a great press of business, but in every way worthy of the author, and the best reply made to the famous essay of Newman which had called them forth. Butler's life was but short. He caught cold when returning one day from public service; the cold terminated in fever, which proved fatal in a few days. He died on the 5th July 1848. His *Sermons*, published in two vols. by Woodward and Jeremie, have been universally recognized as among the most important recent contributions to theology. They are remarkable not only for rare brilliancy of style, but for subtilty and force of thought. The diction is at times too ornate and rhetorical, but it is not to be forgotten that the sermons were hurriedly written, were never revised, and were all the work of a young man. Their uncommon excellence deepens the regret at the early death of the author. The *Lectures on the History of Ancient Philosophy*, edited in a masterly manner by W. Hepworth Thompson (2 vols. 1856; 2d ed., 1 vol. 1875), have taken their place as the best among the few British works on the history of philosophy. The introductory lectures, and those on the early Greek thinkers, are not of the highest value, and though they evidence wide reading, do not show the complete mastery over the material that is found in Schwegler or Zeller. The lectures on Plato, however, are of great value, and furnish a most admirable and enthusiastically conceived exposition of the Platonic system. Butler was evidently attracted by the lofty spirit of Platonism, and sets forth its main features with the warmest admiration. In details he is not altogether to be trusted, but any defects in his scholarship are amply supplied in the valuable notes of his editor.

See *Memoir of W. A. Butler*, prefixed by Rev. J. Woodward to first series of *Sermons*.

BUTO, an Egyptian goddess, called in the language *Uat* or *Uatiu*, the eponymous goddess of the town Buto in Northern Egypt, supposed to be modern Kum el Aman and Kum el gir, on the western banks of the Damietta branch of the Nile. The goddess herself personified Lower Egypt, and as such wore the *tesĕr* or red crown, whether in her human form, or typified as a vulture, or uræus; in which respect she resembled Nat or Neith. She presided over fire, and resided in it or the solar eye, and was identified with the goddesses Bast and Sexet or Merienptah, of which she may have been another type. Buto was also considered to represent the Greek Latona, and the uræus Mahur, and this again connected her with Lower Egypt or the Delta. She was considered to be the regent and mistress of the lands Pe and Tep, districts of her nome, of the land of *Hanebu* or the Greeks, and of *Tāneter*, the divine land or Arabia, also of *Anhu* the capital of *Xrut*, another of the nomes of Lower Egypt. The ideas of the Greeks that she personified darkness, and that the *mygale* or shrew-mouse was sacred to her, are incorrect; for, as already stated, *Uat* presided over the element of fire, and the shrew-mouse appears from the inscriptions on the base of figures of this little animal to have been dedicated to Horus, like the Apollo Sminthens of the Greeks. The name was also given to the capital of a nome ruled over by the deities Har or Horus and Uat or Buto. The Greeks supposed that Buto was the capital of Chemmites or Phthenotes close to the Boutikè Lake, the present Burullos, near the old Sebennytic branch of the Nile. It contained several temples, and in that of Buto oracles were delivered, and the temple was 10 *orgyiai* or fathoms high. The most remarkable object, however, in it was the monolith shrine 40 cubits or about 60 feet square, with a roof of stone, 4 cubits or about 6 feet thick, and 5000 tons weight. It was brought from Elephantina. It appears from an inscription found at Cairo that, during the Persian occupation of Egypt, Khabash, then the ruler of Egypt, had given the nomos Phthenotes to the state of Buto, but that this arrangement was not recognized by Xerxes. Subsequently the older arrangement was restored by Ptolemy Lagus about 313 B.C.

Herodotus, ii. 155; Reinisch, *Denkmäler in Miramir*, s. 201; Wilkinson, *Mann. and Cust.*, iii. 330, 331, iv. 271–3, v. 40; Brugsch, *Geographie*, i. s. 58; Jablonski, *Panth. Ægypt*, iii. 84–116; *Zeitschrift für ægyptische Sprache*, 1871, p. 1 and *foll.*

BUTRINTO, a fortified town of European Turkey on the coast of Albania, in the sandjak of Delvino, directly opposite the island of Corfu, and situated at the mouth of a stream which connects the Lake of Vatzindro with the bay. It has a small harbour, and is the seat of a Greek bishop. In the neighbourhood are the ruins of the ancient *Buthrotum*, consisting of a Roman wall, about a mile in circumference, and some remains of both later and Hellenic work. Buthrotum was a Roman colony in the time of Strabo, but makes little figure in ancient history. The modern city belonged to the Venetians till 1797, when it was seized by the French, who in 1799 had to yield to the Russians and Turks. Population, 1500.

BUTTER, is the fatty portion of the milk of mammalian animals. The milk of all mammals contains such fatty constituents, and butter from the milk of goats, sheep, and other animals has been and may be used; but that yielded by cow's milk is the most savoury, and it alone really constitutes the butter of commerce. The milk of the various breeds of cattle varies widely in the proportion of fatty matter it contains; its richness in this respect being

greatly influenced by season, nature of food, state of the animals' health, and other considerations. While the proportion of cream to milk in the case of most breeds ranges from one-twentieth to one-tenth; in the case of the celebrated Alderney cattle it amounts to as much as from three to four-tenths. Dr Parkes (*Practical Hygiene*) gives the following as the average composition of unskimmed milk having a sp. gr. of 1·030 :—

Casein	4·0
Fat	3·7
Lactin (Sugar of Milk)	5·0
Salts	0·6
Total Solids	13·3
Water	86·7

On a low average each pint of milk ought to yield a full half-ounce of butter. The fat or butter is disseminated through freshly-drawn milk in minute, clear globules, each of which is enclosed in a thin membranous sac or bag; and being specifically lighter than the mass of the fluid, the globules gradually rise to the surface, bringing mixed with them a proportion of milky matter, and form cream. Usually the cream is skimmed off the surface of the milk for making butter, but by some the churning is performed on the milk itself without waiting for the separation of the cream. The operation of churning causes the rupture of the oil sacs, and by the coalescence of the fat so liberated butter is formed. Details regarding churning and the preparation of butter generally will be found under DAIRY.

Fresh or unsalted butter of good quality should present a rich straw-yellow colour. At ordinary temperatures it has a firm uniform consistency, while it is soft enough to cut and spread easily under the knife without breaking or crumbling. It should possess a faint sweet odour, and a bland, soft, delicate flavour, melting in the mouth without any indication of grittiness. Pure butter is a complex chemical compound, consisting in large part of fats or glycerides of the non-volatile acids, palmitic acid, and butyroleic acid, with occasionally stearic acid. With these there occur small proportions of glycerides of the volatile acids, butyric, capronic, caprylic, and caprinic acid, to which the butter owes its distinguishing flavour and characteristics, as it has the non-volatile acids in common with other fats, though in different proportions. Butter when unadulterated and prepared with ordinary care should contain at least 85 per cent. of pure fat, the remainder consisting of casein, water, and salt. The casein is derived from milk, which is never perfectly washed out, but in butter of good quality this ought not to amount to more than from 3 to 5 per cent. Water may be present to the extent of from 5 to 10 per cent. without the butter being subject to a charge of adulteration; and a small proportion of salt is commonly worked into the butter in its preparation, but in what is sold as fresh or sweet this should only be from ½ to 2 per cent. of the whole weight.

When butter is exposed to the air for some time, especially in warm weather, or in hot, confined situations, it quickly becomes rancid, acquiring thereby a distinct disagreeable odour and a biting taste, owing to the development of a volatile fatty acid under the influence of a species of fermentation, which is doubtless caused by the nitrogenous substance, casein, it contains. The more completely, therefore, all milky and curdy matter is washed out of butter the less will be the tendency to set up and develop fermentation. The preservation or curing of butter depends for its efficacy on the employment of some agency by which fermentative action may be prevented; but there are also several ways by which its development may be retarded and the material kept sweet for a considerable period. Rancidity may be corrected to some extent by melting the affected butter and pouring it into ice-cold water. As a means also of retarding rancidity, butter is in some parts of France and the East melted up and heated till the water it may contain is evaporated, when the casein which rises as a scum to the surface is carefully skimmed off; but butter cannot be so melted without injuriously affecting its delicate flavour. By keeping fresh butter in a very cool place covered with pure water renewed daily, it will remain sweet for a considerable time. A still better method, recommended by M. Payen (*Substances Alimentaires*) is to use water acidulated with either tartaric acid or vinegar. It is also said that sugar in the form of a syrup poured over the butter is an excellent medium for retarding rancid fermentation. Butter, however, which is to be kept for a considerable length of time is "cured," or preserved by incorporating with it some substance or substances which act upon the nitrogenous material it contains, and thus prevent fermentation; and for this purpose common salt is the agent chiefly relied on. The salt used should be pure, dry, and finely powdered. About 5 per cent. of salt is sufficient for the purpose of curing; and when the quantity exceeds 8 per cent. it ought to be regarded as an adulteration. Butter very lightly salted for keeping only a short time is said to be powdered. A mixture much used for curing butter in Continental dairies is thus prepared:—One part each of sugar and nitre are mixed up with two parts of common salt and reduced to a very fine powder. This mixture is thoroughly kneaded into the butter in the proportion of about 1 oz. to every ℔. After standing over for a fortnight butter so prepared will be ready for use and have a soft, agreeable taste, which it will retain a long time. In the preservation of all butter, the exclusion of air, as much as possible, is of the utmost consequence. It is, therefore, packed for sale in oaken kegs or glazed earthenware jars, filled quite full, and covered with a clean linen cloth on which salt is sprinkled. When in use the kegs should also be closely covered over, and the surface of the butter kept under brine.

Butter of good quality is a most digestible form of fat, while its flavour is so delicate and little pronounced that it is always acceptable to the palate. It is used most extensively by all classes, not only in the direct form with bread at nearly every meal, but also as entering very largely into the preparation of pastry, puddings, sauces, fancy cakes, and biscuits. Taking into account the daily consumption of this article, it is evident that the amount used in a year by a population such as that of Great Britain must be very great, an inference borne out by the fact that in 1875 the imports were 1,619,808 cwts., valued at £9,050,025, and, though no means exist of accurately estimating the home produce, it may safely be regarded as equal to the whole imports. The countries whence butter is imported into Great Britain are chiefly Germany, Holland, Denmark, and especially France. A large proportion of the French butter comes from the department of Calvados—Isigny being the centre of the best butter-making district. The value of the total produce of France in 1867 was estimated at 250 millions of francs.

Butter is a substance which affords great scope for adulteration, and its composition makes accurate detection of certain foreign matters a matter of considerable labour and difficulty. Other animal fats, such as lard, beef and mutton dripping, and tallow, with certain vegetable fats, are the chief adulterants. Such adulterations may be suspected by their characteristic smell, and detected by their different melting points, by microscopical examination, and by their ethereal solutions. Messrs Angell and Hehner have proposed a convenient method of estimating the fusing points of fat by placing a given weight of definite size on the fat, and observing the temperature at which it sinks into the substance. They find that the sinking-point for genuine butter

is remarkably constant, and that it is affected in proportion to the amount and sinking point of any adulterant fats used. Their analysis of butter depends upon the much smaller proportion of non-volatile, insoluble fatty acids it contains, as compared with fats used as adulterants.

Under the name of butterine an artificial substitute for butter has been introduced in America, and imported into England from New York. It is the same as the artificial butter or "margarine-mouries," which has been for some years manufactured in Paris according to a method made public by the eminent chemist M. Mège-Mouries. Having surmised that the formation of butter contained in milk was due to the absorption of fat contained in the animal tissues, M. Mouries was led to experiment on the splitting up of animal fat. The process he ultimately adopted consisted in heating finely-minced beef suet with water, carbonate of potash, and fresh sheep's stomachs cut up into small fragments. The mixture he raised to a temperature of 45° C. (113° Fahr.) The influence of the pepsine of the sheep's stomach with the heat separated the fat from the cellular tissue; he removed the fatty matter, and submitted it when cool to powerful hydraulic pressure, separating it into stearin and oleomargarin, which last alone he used for butter-making. Of this fat about the proportions of 10 ℔ with 4 pints of milk and 3 pints of water were placed in a churn, to which a small quantity of arnotto was added for colouring, and the whole churned together. The compound so obtained when well washed was in general appearance, taste, and consistency like ordinary butter, and when well freed from water it was found to keep a longer time. According to French official reports artificial butter goes much further as food than the genuine article, and forms a perfectly wholesome dietetic material. The Parisian *octroi* officials have recognized the efficiency of the substitute by imposing on it the same duties which are chargeable on ordinary butter. The company established for the manufacture in France had in 1874 seven manufactories, in which four hundred men were employed. There can be no doubt that a pure, sweet fat, such as is manufactured by the process of M Mège-Mouries is a safer and more wholesome article than the unsavoury rancid butter which is sold so freely among the poorer classes. See Dairy.

BUTTERFLIES and MOTHS, the common English names applied respectively to the two groups of Insects which together form the order *Lepidoptera* (Gr. λεπίς, a scale, and πτερόν, a wing), an order characterized by the constant presence, in a greater or less degree, of scales on the wings. The two groups may, as a rule, be readily distinguished from each other, although, so far as our present knowledge goes, there is nothing in the structure or habits of either group which divides it entirely from the other. All butterflies are diurnal in their flight, while moths, with many exceptions, are crepuscular or nocturnal.

icture. The bodies of butterflies and moths, like those of all other insects, consist of three distinct parts—the head, bearing the organs of sense; the thorax, the organs of locomotion; and the abdomen, the organs of generation.

ad. On the head are placed (1) the antennæ, composed of numerous articulations, and supposed to be organs of hearing. They differ greatly in form among the *Lepidoptera*; those of butterflies, however, agreeing generally in having their ends knobbed or clubbed, hence the term Rhopalocera (ῥόπαλον, a club; κέρας, a horn), often applied to this group. The antennæ of moths assume a great variety of forms—prismatic, serrate, pectinate, moniliform, and filiform,—and are often beautifully feathered, especially in the males, whose antennæ are usually ampler than those of the females; but in no case are they knobbed, as in the great majority of butterflies. Owing to this variety in the form of their antennæ, moths have been termed Heterocera (ἕτερος, various; κέρας, a horn). In butterflies these organs are also straight, and stand out rigidly in front of the head, while in moths they are usually curved and can generally be folded back on the body. (2) The eyes in the *Lepidoptera* consist of two masses of hexagonal facets, placed one on each side of the head, and forming what are known as compound eyes. These contain in some cases no fewer than 16,000 facets each, while in many species a pair of *ocelli*, or simple eyes, are found concealed among the scales and placed between the compound organs. The hairy appearance of the eyes in many of the *Nymphalidæ* is owing to the presence of minute hairs planted at the angles of the numerous facets. Compound eyes are not found among the larvæ of butterflies and moths, but they are in most cases provided with six ocelli on each side of the head. (3) The mouth, the parts of which in insects are considered by comparative anatomists to be typically developed in the masticatory mouth of beetles (*Coleoptera*), assumes in butterflies and moths the suctorial form—the latter being merely a modification of the former; thus the mandibles, labium, and labrum, which are fully developed when the nature of the food renders mastication necessary, are in a rudimentary condition in the *Lepidoptera*, whose chief food is the nectar of flowers, while the maxillæ, on the other hand, are enormously developed; being concave on their inner sides, these by approximating form a tube known as the proboscis or tongue. This when at rest is coiled up into a ball in front of the head, and is partly concealed by the palpi projecting on both sides. In the moths belonging to the family *Bombycidæ*, the organs of the mouth are rudimentary, so that these insects after entering upon the imago state are incapable of feeding.

The thorax bears the organs of locomotion, consisting of three pairs of legs and two pairs of wings. The former are covered with hairs and scales, and terminate in hooks modified to suit the habits of the various species. Butterflies use the legs almost entirely for resting, very rarely for walking, and in some groups, as the *Nymphalidæ*, the front pair is rudimentary. The wings consist of a double layer of colourless membrane traversed by numerous nervures (Plate XXVII. fig. 1), and covered with minute scales implanted in the wing membrane by a short stalk, and placed together like tiles on a roof. The scales vary in form in different species and in different portions of the wings of the same species, while under a high power of the microscope they are seen to be minutely corrugated; and it is to these corrugations acting upon the colourless rays of light, and producing the phenomena of "interference," that many of the loveliest butterflies owe the brilliancy of their wings. The splendour of those organs in the majority of butterflies, and in some moths, is sometimes equally shared by both sexes, but more usually the females are less conspicuously coloured than the males. This difference, amounting often to total dissimilarity, Darwin, in accordance with his descent-theory, attributes in great part to the action of sexual selection. "Several males," he says, "may be seen pursuing the same female." The latter he supposes selects the most gaily-coloured, and thus the plainer-coloured males have been gradually eliminated; but there is no proof whatever that the female shows any such discrimination in selecting a mate, while many known facts seem to point in an opposite direction. Mr A. R. Wallace maintains, on the other hand, that the duller colours of the females have been acquired for protective purposes, the females requiring such protection more than the males owing to their generally slower flight, and to the fact that after impregna-

tion they take several days to deposit their eggs, during which the life of the male is of no further consequence to the perpetuation of the species. Whatever may be the true interpretation of this phenomenon, it is certain that many butterflies and moths of both sexes are so coloured as to be to a greater or less extent protected thereby. Many moths, which rest by day clinging to the trunks of trees, so exactly resemble in the colour of their upper wings the bark on which they rest as only to be distinguished on close examination; while many small species which habitually rest on leaves are often mistaken for the droppings of birds. The upper surfaces of the wings of butterflies are in almost all cases the more gaily coloured, and when at rest, these are raised perpendicularly over the back, so as only to expose the under surfaces, which are often dull coloured, and in some cases have been shown to be directly imitative of surrounding objects. The best example of this is to be found in the Malayan butterfly, *Kallima paralekta*, and its Indian ally, *Kallima inachis*, both brilliant and conspicuous insects on the wing, but which no sooner alight than they become invisible. The under surfaces of their wings, though varying greatly, yet form in every case a perfect representation of a leaf in some stage or other of decay, the butterfly at the same time disposing of the rest of its body so as to bear out the deception. How this is effected is best told by Mr Wallace, who was the first to observe it, in his valuable work on the Malay Archipelago.

"The habit of the species is always to rest on a twig and among dead or dried leaves, and in this position, with the wings closely pressed together, their outline is exactly that of a moderately sized leaf slightly curved or shrivelled. The tail of the hind wings forms a perfect stalk and touches the stick, while the insect is supported by the middle pair of legs, which are not noticed among the twigs and fibres that surround it. The head and antennæ are drawn back between the wings so as to be quite concealed, and there is a little notch hollowed out at the very base of the wings, which allows the head to be retracted sufficiently."

Moths, when at rest, have the hind wings folded close to the body, while the fore wings cover all, and it is the latter that usually show an assimilation in colour to surrounding nature. Many butterflies and moths, there seems good reason to believe, are coloured in imitation of other and often widely different species possessing some special means of protection, as sting or nauseous juices, the mimetic forms, it is supposed, sharing with their models in immunity from the attacks of insectivorous animals. The phenomena of mimickry were first observed by Bates among the *Heliconidæ*, a family of South American butterflies, remarkable for their great numbers, the gaudiness of their colouring in both sexes and on both surfaces of their wings, and for their comparative slowness of flight. It was found that, owing to the nauseous nature of their juices, those brilliant butterflies were left unmolested by insect-eaters. It was also observed that several species of a genus closely allied to our Cabbage Butterflies, totally different both in the colour and form of the wings from the *Heliconidæ*, so closely resembled particular species of the latter as not to be distinguishable from them on the wing. Exactly similar phenomena have been observed in the tropical regions of Asia and Africa, where the similarly protected *Danaïdæ* and *Acræidæ* find imitators among the otherwise unprotected Papilios and Diademas. There are two families of day-flying moths, *Sesiidæ* and *Ægeriidæ*, with clear transparent wings, the scales being confined mainly to the margins and nervures, which in their wings and in the form and colour of their bodies might be readily mistaken for bees or wasps, a similarity recognized in such specific names as *bombiciformis, apiformis, vespiformis*, &c., applied to different species of these moths. Other species of the same "clear wing" group have opaque wings closely resembling those of certain species of *Coleoptera* found in the same neighbourhood, and these have their wings when at rest closed over their bodies like the elytra of beetles.

Metamorphosis.

Butterflies and moths undergo complete metamorphosis, that is, after emerging from the egg, and before attaining the full development of the imago, they pass through the larva and pupa stages—the latter being one of total inactivity in so far as the outward manifestations of life are concerned. The eggs vary greatly in shape, and are deposited in a great variety of situations—on the under sides of leaves, on the outside of the cocoon, as in the Vapourer Moth (*Orgyia antiqua*), the female of which is wingless, glued together in rings round the smaller branches of fruit trees, as in *Clisiocampa neustria*, or in the interior of hives, the larvæ afterwards feeding on the wax, as in the Honey-comb Moth (*Galleria cerella*). They thus show a remarkable instinct in depositing their eggs in situations where the larvæ may afterwards obtain their appropriate food, although they themselves can have no knowledge of that food.

Caterpillar.

The caterpillar emerges from the egg usually in a week or ten days. Unlike the perfect insect it is provided with a masticatory mouth. It has three pairs of legs on the anterior segments of its body, corresponding to the six legs of the future imago, besides which it is provided with a variable number of conical feet or *prolegs* placed posteriorly, and which are merely processes of the external covering of the caterpillar. Goossens, a Continental naturalist, has recently observed that the number of prolegs in some species differs at different ages, and gives a case in which a caterpillar with originally six prolegs acquired two additional pairs after the third moult. The body cavity is almost entirely occupied with the digestive system, and with that concerned in the production of the silky material used in forming the cocoon. Silk is secreted as a viscous fluid in tubes, which after many convolutions widen into a large reservoir filled with the yellow liquid, narrowing again into a tube extending to the mouth, where it communicates with the outside by means of a conical and jointed papilla known as the *spinneret*. Through this organ the viscous fluid is forced in two exceedingly delicate streams which coalesce, and on exposure to the atmosphere harden into a single continuous thread. The silky material is not completely formed till the caterpillar reaches maturity. Caterpillars are either smooth skinned or more or less covered with hairs; in the former case they are a favourite food of insectivorous animals, while in the latter they are almost universally rejected,—recent investigations on this subject going to prove that the hairs on certain species of caterpillars have a power of stinging, somewhat analogous to that possessed by the hairs on the surface of a nettle.

No sooner does the caterpillar emerge from the egg than it begins to eat voraciously, and in a few days has grown so large that a change of skin becomes necessary. The old skin is cast off, and with it the entire internal lining of the alimentary canal, and in the majority of butterflies and moths five such changes take place before the caterpillar has attained its full growth, while the Tiger Moth (*Arctia caja*) is said to cast its skin at least ten times. Those moultings do not usually affect the appearance of the caterpillar, except in enlarging it; but in the case of *Samia cecropia*, a species of *Bombycidæ*, the larvæ are said to pass from black to various shades of green and azure-blue in the course of their moultings. The larvæ of the family *Psychidæ*—the larger members of which are found in America and Australia—have the curious habit of constructing cases which they carry about with them, and within which they afterwards undergo transformation. Each larva has but a single case, and when this gets too narrow it splits longitudinally and is enlarged by interpos-

ing a new portion between. Moths and butterflies remain in the larval condition for periods varying from three years, as in the Goat Moth (*Cossus ligniperda*), to a few weeks, as in the Cabbage Butterfly (*Pieris brassicæ*), which usually has two broods in the season, while many species whose larvæ leave the egg in autumn, as the Blue Butterfly (*Polyommatus alexis*), remain torpid throughout winter at this stage, and waken up to resume feeding in spring. During this period they increase enormously in weight; thus the larva of the Privet Hawk Moth (*Sphinx ligustri*) which casts its sixth and last skin on the twenty-second day after emerging from the egg, attains its greatest size ten days after, having in the meantime increased to 11,312 times its original weight; while the Goat Moth (*Cossus ligniperda*), which remains in the larval condition for three years, has grown in that period 72,000 times heavier. Having attained its full growth the instincts of the caterpillar undergo a change; it ceases to eat and begins to weave a couch or cocoon by which it is more or less enclosed. It then throws off its skin and appears as a pupa or chrysalis incapable of eating or of locomotion, the only apparent sign of life which it manifests being a convulsive twitching when irritated. Examined more closely, however, life is seen to be exerted in very great intensity in this stage of apparent quiescence. The immense digestive system of the caterpillar dwindles greatly, the rudiments of wings begin to show themselves, forming slight prominences on each side of the chrysalis shell, while the organs of the masticatory mouth are being transformed into those of the suctorial. In assuming the pupa condition caterpillars dispose of themselves in a great variety of ways. Many, like the common Cabbage Butterfly, ascend walls and palings, to which they attach themselves by a silken belt, others, as silkworms, spin around them a solid cocoon of pure silk; while the majority of Sphinx Moths form burrows in the ground, which they line with silk and afterwards varnish to keep out the moisture,—one of these (*Sphinx ligustri*) remaining thus buried from August till June. Those larvæ which feed on the wood of trees, as *Cossus ligniperda*, generally form tough cocoons of chips of wood and of silk within the tunnels which they have bored in the tree, and their pupæ have the power of forcing themselves along those passages till they reach the bark, where they remain until about to emerge from the egg, when they pierce it also. The cocoon of the Puss Moth (*Cerura vinula*), composed of the same materials as in the preceding instance, is usually placed in a crevice of the bark of a tree, where by exposure to the atmosphere it becomes hard as horn, the moth only making its escape after discharging a liquid by which one end of the cocoon is softened. Hairy caterpillars are usually deficient in silk, and in forming their cocoons mix what they have of this with the hairs of their body. A beautiful net-like cocoon is woven by a South American moth belonging to the *Bombycidæ*, which it suspends from the top of an outstanding leaf. "When the caterpillar," says Bates, "begins its work it lets itself down from the tip of the leaf which it has chosen by spinning a thread of silk, the thickness of which slowly increases as it descends. Having given the proper length to the cord (about 6 inches) it proceeds to weave its elegant bag, placing itself in the centre and spinning rings of silk at regular intervals, connecting them at the same time by means of cross threads, so that the whole when finished forms a loose web with quadrangular meshes of nearly equal size throughout." The duration of the pupa stage varies from a few weeks to several months; it varies also in the same species according to the season at which it becomes encased; thus the pupa of *Vanessa urticæ* at the beginning of summer usually develops in fourteen days, and at midsummer in eight or nine days, while if it becomes encased in autumn it remains a pupa during the winter. By applying heat the process can be accelerated, and it can be equally retarded by refrigeration. When mature the pupa case cracks towards the anterior end, and the butterfly or moth crawls forth with wings which, though at first small and crumpled up, in a few hours attain their full size. The male insect goes in search of the female, and when the latter has deposited her eggs the main object in the life of the imago is attained and both sexes die. Among the *Bombycidæ* this occurs in two or three days, owing to the atrophied condition of the organs of the mouth. With butterflies courtship is generally a more prolonged affair, several males pursuing the same female, and breaking each others wings in the conflicts that thus frequently ensue. Butterflies appear in many cases to be gregarious, flying in great flocks. Bates states that at one place in South America he noticed eighty different species flying about in enormous numbers in the sunshine, and these, with few exceptions, were males, the females remaining within the forest shades. Darwin also describes a "butterfly shower," which he observed ten miles off the South American coast, extending as far as the eye could reach; "even by the aid of the telescope," he adds, "it was not possible to see a space free from butterflies. That they are occasionally migratory as well as gregarious is borne out by the observations of Sir J. Emerson Tennent, who witnessed in Ceylon a mighty host of butterflies of a white or pale yellow hue, "apparently miles in breadth and of such prodigious extension as to occupy hours and even days uninterruptedly in their passage."

Imago.

Food.

The food of Lepidopterous insects consists chiefly of the sweet liquids drawn from the nectaries of flowers, which they reach by means of their long proboscis or tongue. Many of the *Sphingidæ* are said to do this without settling on the flowers, and one of these, the Humming Bird Hawk Moth of South America (*Macroglossa titan*), in its mode of flight and of poising itself before a flower while extracting the juice, bears such close resemblance to certain of the smaller humming birds inhabiting the same district, that Bates often shot it for one of the latter, and it was only after considerable experience that he learnt to distinguish the bird from the moth when on the wing. Although their food is thus usually the sweetest liquids drawn from loveliest vessels, still some of the most brilliant species seem to prefer more vulgar fare. Thus the showy Purple Emperor (*Apatura iris*) prefers above all things to suck the juices of putrid animal substances, and the surest way to secure specimens of this butterfly is by setting such baits near its haunts. Mr Wallace states that in Malacca he caught a large and brilliant butterfly which had settled on the dung of some carnivorous animal, where he had also observed it on the previous day, and he adds that it is a habit of many of the finest butterflies to suck up the liquid from muddy spots on the roadside.

Distribution.

Butterflies and moths are widely distributed all over the globe, occurring, however, in greatest variety and abundance in tropical lands. They are found as far north as Spitzbergen, on the Alps to a height of 9000 feet, and to double that height on the Andes. In Britain there are only 66, and in the whole of Europe 390 species of butterflies; while within one hour's walk of Pará in Brazil, Bates found no fewer than 700 species. There are 1910 species of British moths, the majority of which are nocturnal and crepuscular; while in tropical America day-flying moths seem to be most common, and may be seen in company with the sunshine-seeking butterflies. This paucity of nocturnal moths has been attributed to the great number of night-flying or crepuscular insectivorous bats and birds which haunt those regions. Many species both of moths and of butterflies have a very wide distribution; the Painted Lady (*Vanessa*

cardui), a common British species, being found in every quarter of the globe; and our finest butterfly, the Swallow Tail (*Papilio machaon*), occurring throughout Europe, Asia as far as the Himalayas, and South Africa. Other species are extremely local, as the Scotch Argus (*Lycæna artaxerxes*), confined to a few Scottish hillsides. Keferstein estimates the total number of *Lepidoptera* at 66,000 species—6000 butterflies and 60,000 moths. That such estimates, however, are not to be relied on is sufficiently proved by the fact that Bates gives the number of species as above 200,000. The geographical distribution of certain groups of *Lepidoptera* has been well wrought out by Mr Wallace and other naturalists who have studied them in their native homes; but the division of this great order into geographical zones has still to be satisfactorily accomplished. Koch has recently proposed to place them in five such groups—(1) the European or Western fauna, including Northern Asia, the North of Africa (a region exceedingly poor in *Lepidoptera*, owing probably to the want of great forests, and to the marshy nature of vast tracts of land), and the northern parts of North America; (2) the African fauna, allied to the preceding; (3) the South Asiatic or Indian; (4) the Australian and Polynesian, allied to the Indian; and (5) the American fauna, distinguished by its exceeding richness.

ca- BUTTERFLIES.—Linnæus included all butterflies under the single genus *Papilio*, but later writers have divided them into several well-defined families, and into numerous genera. The largest and most magnificent species belong to the *Ornithoptera* or "Bird-winged Butterflies," a genus of *Papilionidæ*, whose wings, measuring fully 7 inches across, are of a velvety black and brilliant green colour, the latter in such species as *Ornithoptera crœsus* being replaced by fiery orange, while the body is golden, and the breast crimson. They are distributed over the islands of the Malay Archipelago, reaching, according to Mr Wallace, their maximum of size and beauty in the Moluccas. The *Papilios* are a closely allied group, smaller in size but equally brilliant in the colour and form of their wings. They are exceedingly numerous and are widely distributed over both hemispheres. One species only is found in Britain, the handsome Swallow Tail (*Papilio machaon*) (Plate XXVII. figs. 1, 2), formerly abundant in many parts of England, but now confined to the fen districts of Cambridgeshire, Norfolk, and Huntingdon. When alarmed the larvæ of this and of other species of Papilios protrude from the upper part of the neck a soft forked horn that usually diffuses a penetrating and unpleasant odour. One of the most elegant of exotic species is the Malayan *Papilio memnon*, with black and blue wings, 6 inches in expanse, and with the edges of the hind pair gracefully scalloped. This butterfly, though common enough in collections, has recently gained additional interest from the fact, discovered by Mr Wallace, of the remarkable variety in the form of the females, a variety which has led to their being described under several specific names. In one group the females resemble the males in shape, though differing greatly—as many female butterflies do—in colour. In another group they differ both in colour and in the form of the hind-wings. These, Mr Wallace says, are "lengthened out into large spoon-shaped tails, no rudiment of which is ever to be perceived in the males or in the ordinary form of the females." He also found that in shape and colouring those tailed females when on the wing, closely resembled another butterfly belonging to a different section of the same genus, *Papilio coön*, which he considers is thus mimicked by the erratic females of *Papilio memnon*. Strange to say both forms of female are produced from the eggs of either form. The genus *Parnassius*, which seems peculiar to the Alpine or subalpine countries of Europe and the North of Asia, belongs also to the *Papilionidæ*. One species, *Parnassius apollo* (Plate XXVII., fig. 3), has semi-transparent wings, spotted with black and vermilion, and is common in most of the mountain ranges of Europe, where it forms a very striking object. The Brimstones (*Gonepteryx*), the Clouded Yellows (*Colias*, Plate XXVII. fig. 4), and the White Butterflies (*Pieris*, Plate XXVII. fig. 6), many of which are abundant in Britain, and the larvæ of which in most cases make great havoc among garden vegetables, belong to the family *Pieridæ*. That the caterpillars of this group are not fatal to the very existence of certain of our most useful vegetables is due solely to the ravages of the ichneumon flies, the larvæ of which are parasitic upon these caterpillars, to such an extent that in every hundred larvæ of the common Cabbage Butterfly, there are probably not more than two or three entirely free from the ichneumon fly (*Microgaster glomerata*), and few caterpillars so attacked ever reach maturity. The species belonging to the family *Nymphalidæ* have only four legs fitted for walking, the anterior pair being rudimentary. They include the majority of the showy butterflies of temperate regions, as the Peacock Butterfly (*Vanessa io*, Plate XXVII. fig. 9), conspicuous from the "eyes" on the upper surface of its wings. The brilliant colouring of the upper surface is in marked contrast to the sombre hues of the under, which give it when resting on the branch of a tree the appearance of a dried leaf, and so is to a considerable degree protective. The Fritillaries (*Argynnis*, Plate XXVIII. fig. 2) have the under surfaces of the wings ornamented with shining silvery disks, and, except a few tropical species, are the only butterflies which have the under surface more gaily coloured than the upper. The Purple Emperor (*Apatura iris*) is one of the largest and most striking of British species. It is a powerful flyer, frequenting the tops of the highest trees, and is thus difficult of capture unless when brought near the ground by the attraction of some putrid carcase. To the same family belongs *Nymphalis jasius* (Plate XXVIII. figs. 7 and 9), one of the most beautiful of European species. The *Heliconidæ* (Plate XXVII. fig. 7) are a family of South American butterflies, so numerous both in species and in individuals, and of such showy colours on both surfaces of the wings, as to form, says Bates, "a feature in the physiognomy of the forest compensating for the absence of flowers." Their wings are long and narrow, they fly lazily, and might thus be supposed to be specially liable to the attacks of insectivorous animals. As already stated, such is not the case, these insects being apparently protected by the nauseous character of their juices. It is this group which is chiefly mimicked in South America, finding imitators in several species of *Leptalis*, a genus of butterflies belonging to the family *Pieridæ*, also in several species of *Erycinidæ*, and in no fewer than three genera of day-flying moths all belonging to edible groups. The family *Morphidæ* (Plate XXVIII. fig. 8) contains the largest and most splendid of the South American butterflies. Their wings, often 7 inches in expanse, are generally of a brilliant metallic blue, which, as the insect flies, flashes in the sunlight so as to be visible, it is said, a quarter of a mile off. They are found most abundantly in forest glades, through which they sail, only flapping their wings at considerable intervals at a great height, "seldom," says Bates, "descending nearer the ground than 20 feet." The *Satyridæ* (Plate XXIX. fig. 6) are found in every quarter of the globe, and seem equally at home on open plains, in forests, and on the slopes of mountains. Their larvæ feed chiefly on grass, and have the almost unique habit of remaining concealed by day and of coming forth at night to feed. The Marbled White (*Arge galathea*) is the species oftenest met with in Britain. The *Hetairæ* of Brazil, the wings of which are partly-transparent, belong to this

family. One of these, *Hetaira esmeralda*, says Bates, "has one spot only of opaque colouring on its wings, which is of a violet and rose hue; this is the only part visible when the insect is flying low over dead leaves in the gloomy shades where alone it is found, and it then looks like the wandering petal of a flower." The *Hesperidæ* or Skippers (Plate XXIX. figs. 13 and 15), so called from their jerky hesitating mode of flight, show, in the thickness of their bodies, the only partially erect way in which they hold their wings when at rest, and the enclosure of their pupa in a cocoon, a distinct approach to the other great division of the *Lepidoptera*—the moths.

sification of moths.

MOTHS.—The vast collection of species included under this term form eight principal groups, divided into numerous families.

1. The *Sphingina* or Sphinx Moths (Plate XXX. figs. 5 and 6), so called from the curious habit which the larvæ have of raising the anterior segments of their bodies, and remaining motionless in this position for hours, thus bearing a fanciful resemblance to the fabled Sphinx, are for the most part crepuscular and day-flying. They are also known in the type family as Hawk Moths from the strength and velocity of their flight. In common with the vast majority of moths they are furnished with a spine or strong bristle on the anterior margin of the inferior wings, which being received by a process of the under surface of the superior pair, maintains them in a horizontal or somewhat inclined position in repose. They are also usually provided with a greatly elongated tongue, with which they sip their food from flowers, and some species have the power of producing a humming sound. To this group belong the clear-winged moths, *Sesiidæ* (Plate XXX. fig. 12) and *Ægeriidæ*, all day-fliers, and looking more like the bees, wasps, and ichneumons which they are supposed to imitate, than moths; also the family *Uraniidæ* (Plate XXIX. figs. 9 and 14), the species of which are among the most brilliant of *Lepidoptera*,—their wings being of velvety black, relieved by numerous bars of golden green, and the inferior pair prolonged into an elegant tail, closely resembling the same appendage in many of the Papilios. They are all day-fliers, and this, together with their gay colouring and airy forms, led to their being at first classed among butterflies, a position which fuller acquaintance with them in the larva and pupa stages showed to be untenable. The typical species occur in tropical America, where they fly with amazing rapidity and perform annual migrations. The Death's-Head Moth (*Acherontia atropos*) is the largest of European Sphinges, and owing to the peculiar squeaking sound which it utters when alarmed, the death's-head-like markings on the upper surface of its thorax, and its sudden appearance in districts where it may not have been noticed for years, it has for centuries been an object of superstitious dread to the uneducated. Its beautifully marked larvæ feed upon the leaves of the potato, and bury themselves in the ground preparatory to undergoing metamorphosis. The Death's-Head is fond of honey, in search of which its instinct leads it to enter hives, the inmates of which do not attempt to drive it out by means of their stings, but make every endeavour to raise a waxen wall between the moth and their food stores. It is widely distributed over Europe, Asia, and Africa, while closely allied, but still larger forms occur in Australia.

2. The *Bombycina* (Plate XXX. figs. 14, 20-25) are nocturnal moths, with the organs of the mouth in many cases so atrophied as to be unfit for use. These live but a few days, during which the male seeks the female and the latter deposits her eggs. They include the silkworm moths, so important to man from the silken cocoons in which they enclose their pupæ. The silk-producing species are very numerous, but only a few of them have as yet been turned to useful account. The chief of these are the common Silkworm Moth (*Bombyx mori*), a native of China, where its cocoons appear to have been utilized by man from time immemorial. During the 6th century it was introduced into Europe, where it soon flourished wherever the mulberry tree, the leaves of which are the sole food of the silkworm, abounded. On these the larvæ feed for thirty days, after which they begin to spin an oval cocoon of a close tissue of the finest silk, usually of a golden yellow colour, but sometimes white, and which when unravelled forms a continuous thread 1100 yards long. In order to obtain a fresh supply of eggs, the silkworm breeder allows a few of the pupæ to develop into moths; and such is the change wrought upon this species by centuries of domestication that, it is said, they rarely if ever attempt to use their wings. They pair, and the female at once settles on the leaves provided for her, where she deposits her eggs and dies. The Arrindy Silkworm (*Attacus cynthia*), so called from the native name of the castor-oil plant on which its larvæ feed, is a native of India. The cocoon is very large, but the thread is too fine to be readily wound off, and it is therefore usually carded, the yarn being woven into a coarse silk cloth of great durability. The Tusseh or Tussur Moth (*Antheræa mylitta*) is also a native of Upper India, occurring abundantly in the jungles, where its cocoons, so concealed by the leaves as only to be detected by the presence of the dung of the larvæ on the ground, are collected. The Tusseh silk is darker and coarser than that of the common silkworm, but resembles it in being readily wound off. In China there are two oak silkworms from which a coarse silk is obtained, used for the clothing of the Chinese poorer classes; but the most important of the oak-feeding species is the Yama-maï (*Antheræa yama-maï*) of Japan, the silk produced from which was, at least until lately, reserved for the use of the Japanese imperial family. This moth is a beautiful insect, about 6 inches across the wings, of a brilliant golden-yellow colour, with a transparent spot or "eye" near the centre of each wing. Its cocoon is nearly as large as a pigeon's egg, and is of a silvery white within, although externally of a yellowish green. In 1861 it was introduced into France, where it now flourishes, and there is good reason to believe, from the nature of its food and its hardiness, that the Yama-maï may yet be profitably reared in Great Britain. *Tropæa luna*, which feeds upon the liquidambar trees in the southern parts of the United States, with wings of a lemon colour, each with a "transparent eye," and the hind pair prolonged into an elegant tail, is one of the loveliest species of *Bombycina*. Its cocoon is formed of the finest silk. Other well-known forms are the Eggars (*Lasiocampa*, Plate XXX. fig. 26); the Processional Moth (*Cnethocampa processionea*), so called from the habit its caterpillars have of congregating in companies of several hundreds, and of marching to their feeding-grounds in regular columns; the Vapourers (*Orgyia*, Plate XXXI. figs. 2, 3, 4), whose females being almost wingless deposit their eggs on the outside of their cocoons, and the Psyches (*Psychidæ*), whose females in many cases have neither wings, legs, nor antennæ, and never leave the tubes in which they have passed the larva and pupa stages.

3. The *Noctuina* (Plate XXXI. figs. 9 and 14) form an exceedingly large group of nocturnal moths, although even here there are a few exceptional instances of day-flying species. They are distinguished by their stout bodies and narrow forewings, under which when reposing they conceal the inferior and in many cases more brightly-coloured pair. The majority of the species are small and dull in their colours, while a few are among the largest of known insects—the Great Owl Moth of Brazil (*Erebus strix*) measuring nearly a foot from tip to tip of its wings.

larval condition have only four prolegs, the usual number being ten, and in moving these are brought close up to the last pair of thoracic limbs, thus giving the caterpillar a looped appearance, hence the term "loopers" usually applied to these moths; they then hold on by the prolegs, and releasing those in front carry the body forward until the arched appearance is gone. They thus move by an alternate process of looping and straightening their bodies. The larvæ of Geometers have also the curious habit of fixing themselves by their hind feet to the branch of a shrub, throwing the remainder of their bodies out, and remaining motionless in this position for hours, thus exhibiting an enormous amount of muscular energy. They are all protectively coloured, and in the attitude just described so resemble the surrounding twigs as to be readily mistaken for them. Geometers are to be found in sunshine and by night, in midsummer and at midwinter, the Early Moth (*Hybernia rupicapraria*) being caught in January.

5. The *Pyralidina* (Plate XXXI. figs. 17, 19, 20, 23) are a group of small moths readily distinguished by their long slender bodies and large forewings. One of these, *Pyralis vitis*, is very destructive to vines, and another, *Pyralis farinalis*, feeds upon meal and flour. The *Galleridæ*, a family of Pyralidine moths, deposit their eggs in the hives of bees, where the caterpillars, enclosed in silken cases, devour the wax; but the *Hydrocampidæ* (Plate XXXI. fig. 12), which also belong to this section, are probably the most wonderful of all Lepidopterous insects, their larvæ being aquatic, living and feeding in the water, and many of them breathing by gills similar to those of caddis-worms.

6. The *Tortricina* (Plate XXXI. fig. 16) include a great number of small moths exceedingly injurious to orchard and other trees. They are known as "leaf-rollers" from the habit which most of their larvæ have of rolling up the leaves on which they feed, and thus forming a shelter for themselves. The Green Tortrix (*Tortrix viridana*) occurs in the larva state on the oak, to which it often does great injury by stripping the trees of their leaves in the month of June. Throughout Southern Europe the vine is liable to the ravages of another species, *Œnectra pillariana*, while few of our fruit trees are exempt from the occasional attacks of some species or other of the *Carpocapsidæ*, the fruit-eating family of this group.

7. The *Tineina* (Plate XXXI. figs. 21, 24, 25) contain the smallest of the *Lepidoptera*, and are best known as clothes moths. These clothe themselves at our expense in the warmest woollen garments, which they traverse in all directions, leaving behind a gnawed and worn-out path, so thin and bare as to yield to the slightest pressure. They also destroy furs, hair, feathers, and many other articles of domestic economy, and are the exterminating pests of zoological museums. To them we no doubt owe the destruction of the most perfect specimen of the Dodo known, which was once preserved in the Ashmolean Museum of Oxford. By means of their maxillæ these little larvæ shear down the surface of various substances, and uniting the particles by means of their glutinous silk, they thus form protecting habitations, which partake of the nature of the woollen or other stuffs on which the foresight of their parents has placed them. When they themselves increase in bulk, so as to find their abodes as inconvenient as a strait waistcoat, they split them down the middle, and interpose a piece proportioned, no doubt, to their expected as well as actual increase. They add to the length also by ...h materials to the anterior end. The *Tinea granella* ...s in granaries, where it forms an abode for itself by ...eloping several grains in a silken web. These it after...ds eats.

The insects of the remaining group, *Pterophorina*, are remarkable from the peculiar conformation of their wings. Each of these organs is split longitudinally into several branches, all of them delicately fringed. In the genus *Pterophora* (Plate XXXI. fig. 26) the fore wings are divided into two, and the hind wings into three branches; while in *Orneodes* (Plate XXXI. fig. 27) each wing is split into six, and these when the insect is at rest are folded together after the manner of a fan.

Collectic and pre- servatioı

COLLECTION AND PRESERVATION OF LEPIDOPTERA.— Butterflies affect special localities with which it is well for the collector to make himself acquainted. A suitable hunting ground having been selected, the following apparatus is necessary:—a bag-net made of gauze or some equally light material, with a wooden or metal ring and a handle, which may also be used as a walking-stick, for capturing the specimens; pill boxes into which to transfer them from the net; and a wide-mouthed glass stoppered bottle, into which about forty leaves of the common laurel, bruised and cut into shreds, have been previously put. Exposure for a short time to the fumes arising from these shreds will cause the death of the inmates of the pill boxes. They may also be readily killed by pressing the thumb-nail against their thorax. For "setting" Lepidoptera, which if possible should be done before the insect stiffens, entomological pins are required, and these should be gilt in order to prevent the appearance of verdigris at the point where the pin enters the specimen; also a setting-board, with an upper layer of cork, and having a groove in which to lay the body of the insect; and small triangular strips of cardboard known as braces with which to set the wings. The process of drying should not be artificially hastened, as by exposure to heat the wings are certain to warp and the body to shrivel. Should the insect have stiffened before setting, or have been badly set, it can readily be softened again by placing it, as is done in the British Museum, in a shallow earthen vessel containing a layer of damp sand, and covering it with a close-fitting lid until sufficiently soft for resetting. Day-flying moths must be sought for in much the same way as butterflies, while nocturnal species may be regularly met with on the sallow, the honeysuckle, the lime-tree, and the ivy, when these are in flower; and when these and similar natural sources fail, the moth-collector has in *sugar* and *light* two admirable devices for securing specimens. A quantity of the coarsest brown sugar reduced by the addition of beer and water to a syrup, and to which a little rum is added as required, is applied with a brush to the sheltered aspect of the trunks of trees on the outskirts of woods or in the neighbourhood of heaths. At nightfall the collector, lamp in hand, visits the sugared locality, and if the evening be favourable, that is, if it be warm and dull, he is almost certain to have his pains rewarded by an abundance of specimens, chiefly belonging to the *Noctuina*. Moths, it is well known, are readily attracted by light, and in a country or suburban house, in the vicinity of trees, a lamp placed outside an open window, which is sheltered from the wind, with another lamp in the interior of the room, will, if the night be close and dark, be almost certain to attract numbers of moths. Mr Wallace adopted this plan while collecting in Borneo, and he states that in twenty-six nights he collected 1386 moths, "but that more than 800 of these were collected on four very wet and dark nights." In towns moths may often be caught flying about lamp-posts. In preserving the larger moths, especially the *Sphingina*, it is necessary to slit up their stout bodies and remove the contents, replacing these with wadding or paper. The drawers of cabinets containing *Lepidoptera* should be provided with a layer of cork and then papered, with a small bag of camphor attached to a corner to ward off the attacks of the dust-lice, or "mites" as they are usually, but incorrectly, called, the

presence of which is made known by the appearance of a fine powder lying underneath the infected specimens. Insects in this condition should be thoroughly soaked in a solution of spirits of wine and camphor. The appearance of grease on thick-bodied moths is by no means uncommon, but may be removed by dipping the insect in spirits of turpentine and embedding it in calcined magnesia till dry The collector should be careful to keep a register of all his specimens, giving the localities where they were found, and recording any observations that may have been made at the time on their food, habits, &c. A small ticket attached to the pin of each specimen, and bearing its number in the register, is the best way of connecting the specimens in the cabinet with the entries in the register (J. GI.)

BUTTMANN, PHILIPP KARL (1764–1829), a German philologist, was born at Frankfort-on-the-Main in 1764. He was educated at the gymnasium in his native town and at the university of Göttingen. In 1789 he obtained an appointment in the library at Berlin, and for some years he edited *Spener's Journal*. In 1796 he became professor at the Joachimsthal Gymnasium, a post which he held for twelve years. In 1806 he was admitted to the Academy of Sciences, and in 1811 was made secretary of the Historico-Philological Section. He died in 1829. Buttmann's writings gave a great impetus to the scientific study of the Greek language, and his grammar is still a work of value. The first edition of the *Griechische Grammatik* appeared in 1792, and in 1863 the book was in its 21st edition. It has been translated into English. The *Lexilogus*, a valuable study on some words of difficulty occurring principally in the poems of Homer and Hesiod, was published in 2 vols., 1818–25. The English translation by Fishlake has passed through five editions Buttmann's other works were *Ausführliche Griechische Sprachlehre*, 2 vols., 1819–27; *Mythologus*, a collection of essays, 1828–9; and editions of some classical authors. Of these last the most important are *Demosthenes in Midiam*, 1823, and the continuation of Spalding's *Quintilian*.

BUTTON, from the French *bouton*, a small piece of metal or other material used to connect different parts of a garment together by means of a button-hole, and also used for ornamentation. These apparently insignificant articles have produced a great alteration in our style of dress, for without them it would have been impossible to have reduced the flowing robes of our forefathers into our present simple costume. By this process we have lost the picturesque, as far as our garments are concerned, but have gained in compactness and utility. Indeed, the occupations of the present age could not be carried on in the togas and dresses of ancient times. The button manufacture did not assume any special form until towards the close of the reign of Elizabeth. In paintings, commencing with the 14th century, studs or buttons appear as ornaments on the dresses of both sexes; but they were ornaments merely, being drawn without button-holes, and placed where they could serve no practical purpose. They are in general represented as of gold or ivory. At the commencement of the 17th century the trade had greatly increased. but the making of buttons by the needle seems to have been the principal method.

Matthew Boulton, who became the senior partner in the afterwards celebrated firm of Boulton and Watt, as early as 1745, introduced great improvements in the manufacture of buttons, particularly inlaid and steel. When the Soho Works were established near Birmingham, one of the departments was occupied in making steel buttons with facets, that produced a hundred and forty guineas the gross. Gilt buttons came into fashion shortly after the accession of George III. A large shipping trade in buttons was then carried on with the Continent and America, and the workmen's wages at Birmingham averaged from £2 to £4 per week. John Taylor, originally a cabinetmaker, appears to have had a principal hand in promoting improvements in this industry at that time, as far as gilt, plated, and lacquered buttons are concerned. The value of those turned out weekly in his establishment is said to have been about £800. Ralph Heaton improved the making of shanks, a separate branch, shortly before the commencement of the present century.

The metal button trade was in a very flourishing condition, when, indirectly, Lord Nelson may be said to have been the means of overthrowing it. The late B. Sanders was in easy circumstances in Denmark when he was ruined by the bombardment of Copenhagen under our great naval commander. Sanders then came to Birmingham to seek such competence as energy and perseverance could afford. He started in the button manufacture, at first in a small way, introducing a covered button made of cloth or lasting, with an iron shank. His son, of the same name, invented a flexible shank button, that is, one with a tuft of canvas protruding from the back instead of a shank, through which the needle could pass in any direction. It was patented in 1825 and had an enormous sale. The Sanders took out another patent for a similar button covered with silk. A fancy silk button with a central ornament was patented by William Elliott in 1837, which had a great run, so much so that sixty looms were employed in London in making the special material required; and Elliott secured a fortune, although his patent was contested and many imitations were started. But all these kinds of buttons were found to wear on the edges, to remedy which John Chatwin patented a corded edge button. It is said that horn buttons were used as early as 1801, but we find from old Birmingham directories that there were horn-button makers as far back as 1777. At the former period the commonest qualities were 5½d. per gross. Hutton in his *History of Birmingham* refers to "our grandmothers" wearing horn buttons nearly the size of a crown piece. The hoof or horn button is cut into form and dyed and pressed into beautiful designs. This great improvement, however, appears to have been effected by M. Emile Bassot of Paris, who introduced important changes resulting in material progress. The manufacture is still prosecuted in England, but it is of secondary importance.

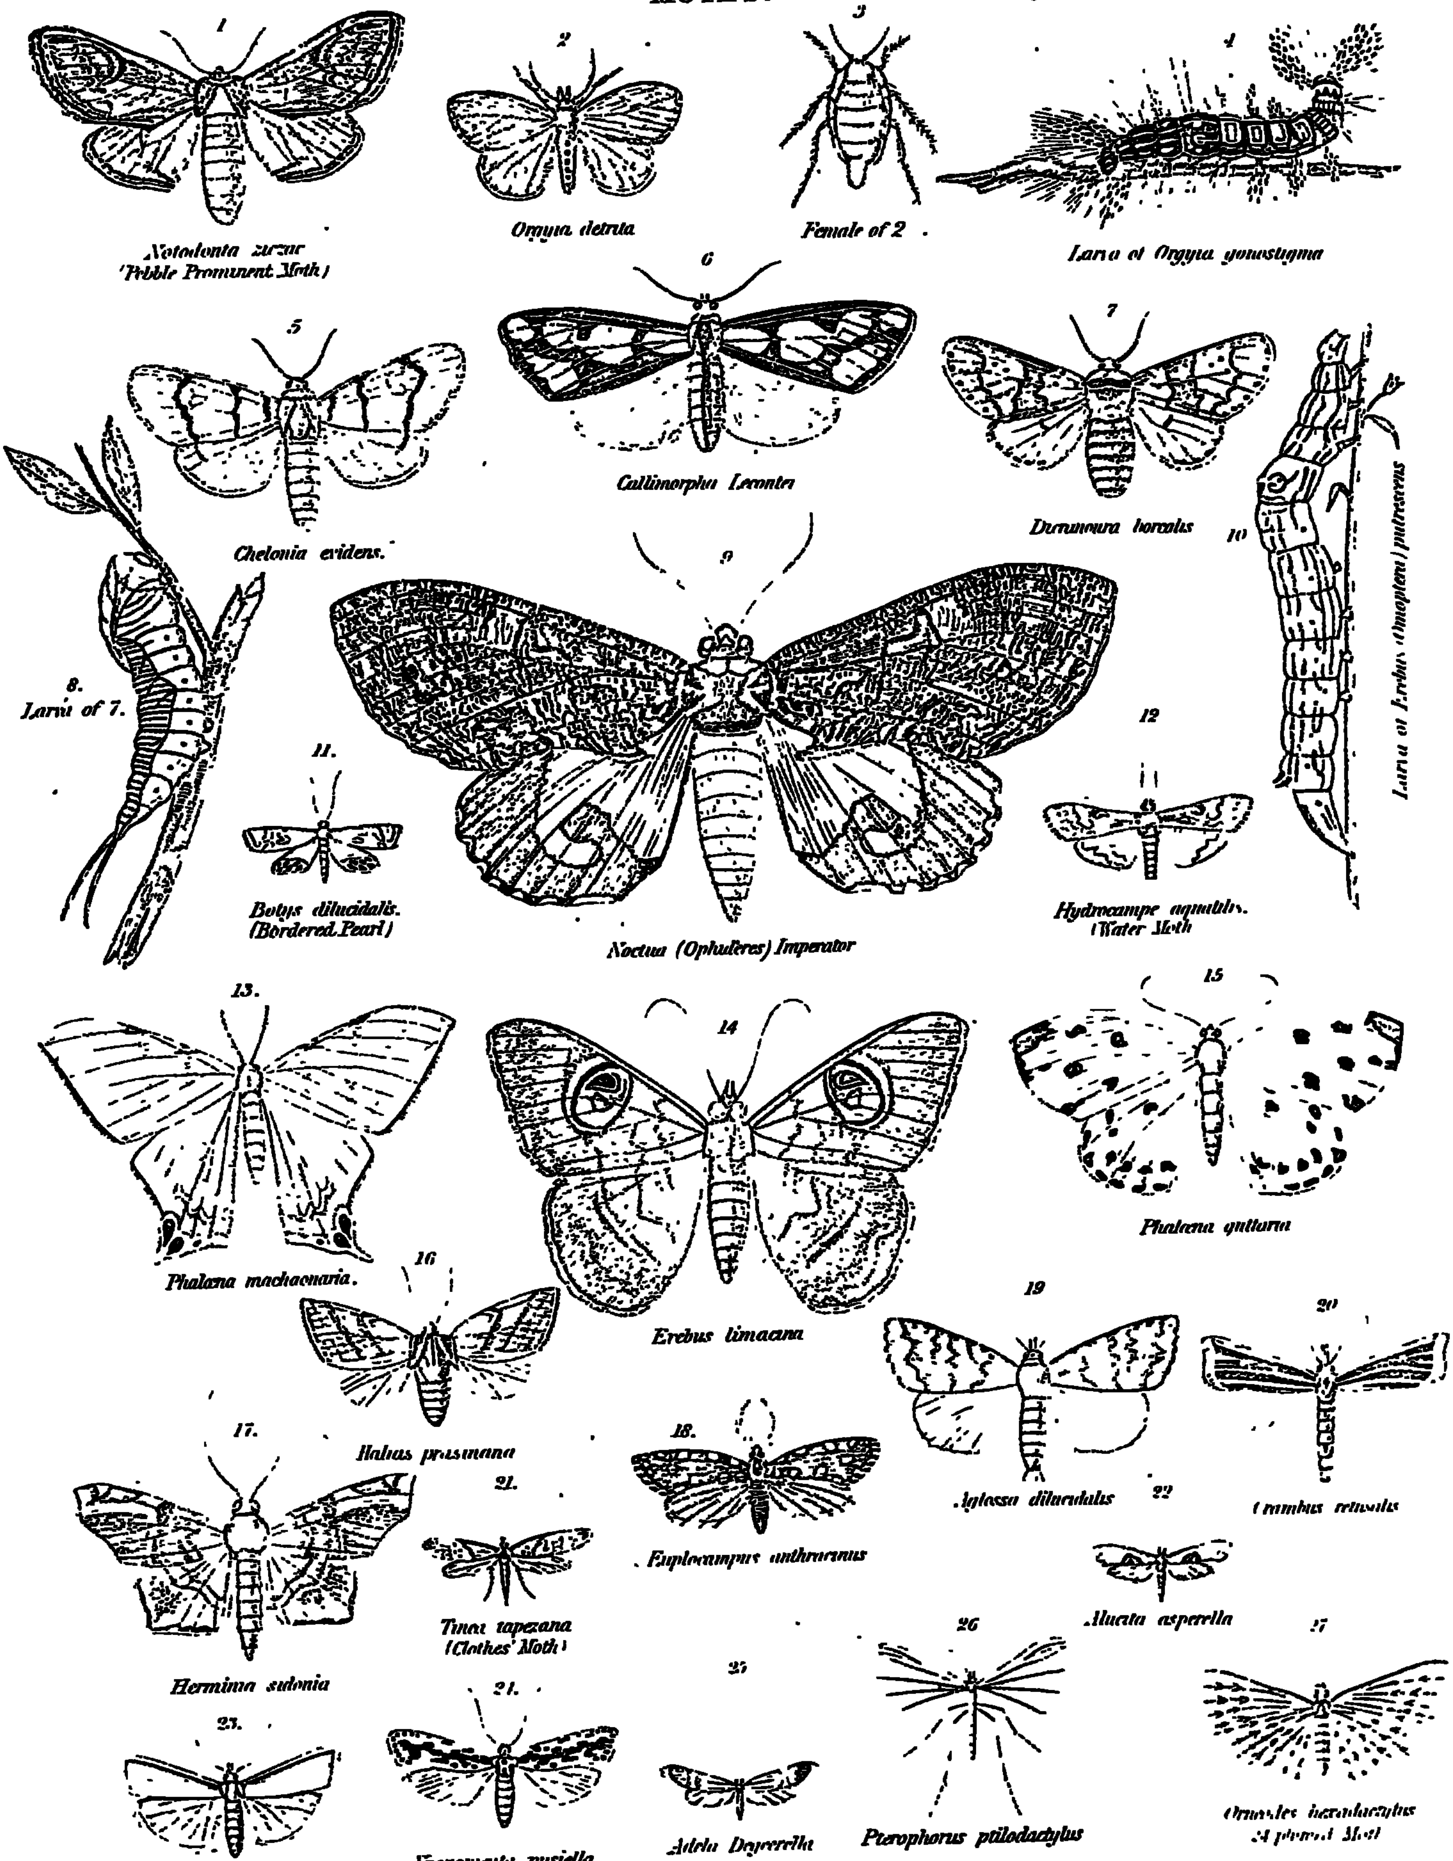
The materials of which buttons are made are as various as their forms. Gold, silver, and other metals, glass, porcelain, horn, bone, india-rubber, mother-of-pearl, and other nacreous productions of shell-fish,[1] various woods, vegetable ivory, &c.,[2] are employed; and for covered buttons, lasting, brocade, twist, velvet, silk, mohair, &c. The Birmingham *Directory* for 1784 mentions paper buttons; and, according to the same authority, a button was produced by "an artist of eminence," which was inlaid with divers other metals; it was first attempted about sixty years previously; and then, "though in no respect so complete as at present, met with great and merited encouragement." Buttons have been often expensively jewelled, and the gold and silver are plain or ornamented, sometimes resembling drops in filigree-work. There was one in use in England about the middle of the last century

[1] The shells are brought from various parts of the world, and vary considerably in price. The white-edged Macassar are the best; the yellow-edged Manilla the next. Those from the Persian Gulf and Red Sea vary much in value, which depends upon the purposes to which they can be applied. Those from the Pacific are beautiful, but, being generally dark in colour, their value is much affected by the turns of fashion. The "Panama shells" are the least valuable, and are generally only used for inferior sorts of buttons.

[2] Vegetable ivory is not very suitable for buttons; it is too soft, and the unavoidable waste in manufacture renders it expensive.

BUTTERFLIES AND MOTHS

MOTHS.



formed of polished brass and ruled with such fine lines that light was reflected in prismatic colours. Some buttons have fetched enormous prices, even when made of what is now a common material. Mother-of-pearl buttons have been sold at a guinea each. In 1790 Henry Clay of Birmingham patented a method of manufacturing buttons of slate or slit stone; and, in 1800, Joseph Barnett introduced a button with two shanks or other fastenings on one button.

Such was the origin of the button industry in England, and other nations have not been behind. The *Scientific American* gives the following account of its commencement in the United States:—

"The first manufacturer of buttons in this country was Samuel Williston. While he was dragging along as a country storekeeper,—his eyes having failed him while studying for the ministry,—his wife bethought her that she could cover by hand the wooden buttons of the time, and thus earn an honest penny. From this the couple advanced in their ambition until they had perfected machinery for covering buttons, the first employed in this country. From this sprang an immense factory, and then others, until Samuel Williston made half the buttons of the world. His factories are still running at Easthampton, coining wealth for the proprietors. . . . . He is now (1871) between seventy and eighty years of age, is worth five or six millions, and has given four hundred thousand dollars to Easthampton for a seminary and for churches; two hundred thousand dollars to South Hadley Female seminary; and two hundred thousand dollars to Amherst College, besides lesser gifts."

The factories of Samuel Williston & Co., above referred to, at Easthampton, Massachusetts, were established about the year 1848, and give employment to about 250 operatives. The annual cost of the materials used is estimated at $75,000, and the value of the produce exceeds $200,000. The button manufacture is also carried on extensively in New York and Philadelphia, and at Waterbury (Conn.). Buttons are also imported extensively. There are five importers in New York (1876). Joel Hayden of Haydenville began to make flexible buttons in the States in the year 1834.

Other countries have not been backward in this branch of industry. Bohemia, particularly at Prague and the neighbouring towns, is the great seat of the glass button manufacture, and great numbers are made in France. The porcelain button manufacture has been taken possession of by France, Minton and Co., the celebrated Staffordshire firm, who worked the invention of R. Prosser of Birmingham, having been driven out of the field by the good work, attended by greater cheapness, of the foreign makers. There is one factory at Milan, and great numbers of the cheaper kinds of buttons are made in the Rhenish provinces of Prussia. Vienna has suppressed the competition of English makers in some kinds of pearl buttons. Its operations in this branch are of a most extensive character, quite rivalling those of Birmingham.

"Button making," says the Birmingham *Directory* for 1777, "was originally a very tedious and expensive process. The button consisted of one solid piece of metal; and the ornaments upon the face of it were the work of an engraver. To obviate this, the press, stamp, and engine for turning the moulds were invented. This led to other improvements, the bones and hoofs of animals were introduced into the manufacture; by these various means the prices of buttons were reduced."

In the manufacture of covered buttons the sheet-iron is first scaled by the use of acids, and then cut into proper shape and size by a machine. The neck or collet of the button is japanned after having been stamped and cut. The hollow between the neck and shell is filled in with brown paper or button board. When the parts are put together they are pressed, which brings them into shape and consolidates them.

It would be impossible in the space that could be devoted to the subject here, to describe in detail the various modes in which the numerous forms of buttons are manufactured,—especially as it would require elaborate illustration. We must, therefore, confine ourselves to noticing some of the special and more recent patents; referring the reader to works where he can obtain such further information as he may require. In 1840 Joseph Parkes took out a patent for improvements in the manufacture of covered buttons made by dies and pressure, by the application of horn as a covering material. Harris's patent for improvements in horn buttons and their dies was obtained in April 1841. This invention related to applying flexible shanks to horn buttons, a mode of ornamentation by inlaying the front surfaces, and also gilding or silvering their surfaces, and to a mode of constructing dies so as to facilitate the process of engraving, the die being also so formed that the horn or hoof employed could not be expressed outside the circumference of the button. Hugh Willoch's patent, dated 5th May 1874, related to a button with a removable head to enable the shank to pass through the button hole. The head is hollow and is partly filled with caoutchouc. It is perforated to admit the shank top, a short transverse bar which, on being turned one-fourth round, falls into an internal groove in the material of the button head, and is retained in that position by the elasticity of the india-rubber. Empson and Palmer's patent, dated 4th July 1874, refers to improvements in linen buttons, and is also applicable to buttons covered with other fabrics. They are composed of a front and back shell, with a bar formed across the face of a raised concentric circle from the back shell (which is all the metal that need be visible in the finished button), the shells permitting ample room for the covering fabrics to be gathered in and held between them. They are considered to resist the injury common to linen buttons during the processes of washing, mangling, and ironing. Tylor's patent, of 13th July 1874, relates to polishing ivory, bone, and similar buttons in a revolving drum with revolving brushes inside. Harrison's invention (8th September 1874) consists in arranging the piercing tools, so that the thread holes for the buttons are made in the pierced metal in front of the shaping and cutting-out tools, and the metal around the groups of piercings is shaped or "domed," and cut out. The result is that at each descent of the compound tool three or more groups of the thread holes are pierced in the sheet metal, and three or more finished buttons are made. The piercings in the sheet metal made by the last descent of the compound tool form the thread holes of the buttons made by the next descent of the said compound tool. When the thread-holes of the button are made in a central depression, a shaping tool for making the said depression is placed between each piercing tool and cutting-out tool. This invention is also applicable to the manufacture of washers, rings, links for chains, and other like articles from sheet-metal. The patent of G. F. Champorez of Berlin, Prussia, relates to improvements in the manufacture of steel or iron and steel dies, and to certain contrivances for producing the same, the said dies being in depression or relief, without recourse to the hitherto universally employed engraving tool. Cole's patent (10th February 1875) relates to a composition for dress-fastenings generally, consisting of black composition of equal parts by weight of gas tar or tar varnish, whiting or chalk or clay, and lamp black or vegetable black. For a coloured composition transparent varnish, or the waste refuse of it, is substituted for gas tar or tar varnish, and a powdered pigment of the required colour is added. The materials should be thoroughly mixed and converted into a plastic, pasty mass, which is consolidated and hardened by rolling and drying. To give

toughness short pieces of fibrous material may be introduced. The articles are shaped from the composition by stamping in stamps or presses, and then varnished and polished.

Messrs Green, Cadbury, & Richards, Birmingham, manufacture a linen button called "The very Button" (Shakespeare), in addition to others of innumerable kinds, and studs for shirts, collars, and wristbands, not only of plain materials but of gold and silver and jewelled. They employ about 400 hands, and turn out weekly from 10,000 to 15,000 gross (12 dozen to the gross) of their linen buttons. The proprietors of this establishment take great interest in the welfare of their workpeople, and few of the adults have been in their employment less than from eight to eighteen years. There is a sick club in connection with the works, and a library containing at present about 1000 volumes. Fines are inflicted for certain irregularities; these, however, are not appropriated by the firm, but are expended, half in the purchase of books, and half as a contribution to the sick club.

The following is a comparative statement of the number of button manufactories at the localities where these articles are principally made, taken from the *Directories* of 1875:—

London, 58; Birmingham, 161; Paris, 140; Berlin, 49; Hamburg, 5; Darmstadt, 3; Offenbach on the Maine, 3; Lubeck, 2; Barmen (Prussia), 27; Elberfeld, 9; Breslau, 2; Lüdenschied (Westphalia), 14; Stuttgart, 6; Vienna—metal, 15; porcelain, 5; shirt, 6; silk, 11; Brussels, 5; New York city, 19; Brooklyn (N.Y.), 3; Philadelphia, 13; Waterbury (Conn.), 8; Boston (Mass.), 3, Attleborough (Mass.), 3; Springfield (Mass.), 2; Newark (N. Jersey), 4.

J. L.)

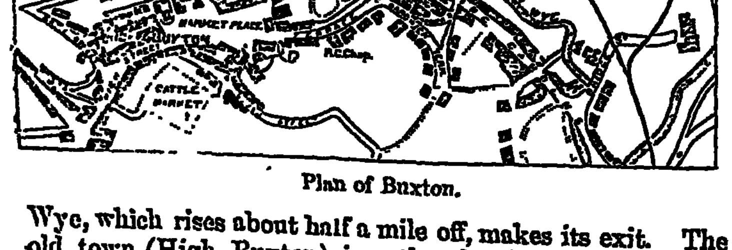
BUXTON, a market-town and fashionable watering-place of England, in the county of Derby, 31 miles N.W. of Derby, and 160 from London, connected with Derby by the Buxton and Rowsley extension line, and with Manchester by the Stockport, Disley, and Buxton Railway. It occupies a high position, being 900 feet above the sea-level, in an open hollow, surrounded at a distance by hills of considerable elevation, except on the S. E. side, where the



Plan of Buxton.

Wye, which rises about half a mile off, makes its exit. The old town (High Buxton) is rather higher than the new, and consists of one wide street, and a considerable market place with an old cross. With the exception of some good inns and lodging-houses, the buildings in this part are commonplace. The new town is of a more elegant character, and has been greatly extended within the last twenty or thirty years. The crescent is a fine range of buildings in the Doric style, erected by the duke of Devonshire in 1779–86, at a cost of £120,000. It contains hotels, a ball-room, a bank, a library, and other establishments, and the surrounding open grounds have been laid out in terraces and gardens under the control of the Buxton Improvements Company. The Old Hall Hotel at the west end of the crescent is remarkable as the site of the mansion built by the earl of Shrewsbury in the reign of Queen Elizabeth, which was the residence of Queen Mary of Scotland when she visited the town. The new church was erected in 1812 by the duke of Devonshire; the edifice which it superseded has since been restored. The mineral waters of Buxton, the most noted in England, are particularly efficacious in cases of rheumatism and gout. There are numerous public and private baths, the most important of which are those in the new and spacious establishment at the eastern end of the crescent. The springs supply hot and cold water at a very short distance of each other, flowing at the rate of 60 gallons a minute. The former possesses a uniform temperature of 82° Fahr., and the principal substances in solution are, according to the analysis of Dr Muspratt in 1860—carbonate of lime, carbonate of magnesia, chloride of sodium, chloride of calcium, and silica. There is also a chalybeate spring known as St Anne's well, situated at the S.W. corner of the crescent, the water of which when mixed with that of the other springs proves purgative. The Devonshire Hospital, formerly known as the Bath Charity, is a benevolent institution, supported entirely by voluntary subscriptions, for the reception and free treatment of poor patients from any part of the country. About 900 or 1000 persons are annually indebted to its founders. The Buxton season extends from June to October, and during that period the town is visited by thousands annually. The public walks are tastefully laid out. The Cavendish Terrace, 500 yards long, forms a fine promenade; there are excellent drives in the park, which occupies more than 100 acres, and the neighbourhood of the town is rich in objects of interest. Of these the chief are—Poole's Hole, a vast stalactite cave, about half a mile distant, now lighted with gas for the convenience of visitors; Diamond Hill, which owes its name to the quartz crystals which are not unfrequent in its rocks; and Chee Tor, a remarkable cliff, on the banks of the Wye, 300 feet high. Ornaments are manufactured by the inhabitants from alabaster and spar; and excellent lime is burned at the quarries near Poole's Hole. Other places of interest, but more distant, are the caverns and mires of Castleton, Haddon Hall, and Chatsworth, the seat of the duke of Devonshire. The population in 1871 within the jurisdiction of the Local Board of Health was 3717; but the fluctuating population during summer varies from 4000 to 5000 at a time.

To judge from the remains of baths and other structures which have at various times been discovered, and the fact that they are situated near the crossing of two military roads, it seems almost certain that the mineral springs of Buxton were known to the Romans; but by what name they were then designated has not been ascertained. We find them a favourite resort in the period before the Reformation, when the patients were in the habit of offering their crutches or articles of attire to the image of St Anne, the tutelar saint, in token of their gratitude for benefit derived from the springs. Sir William Basset, at the command of Henry VIII., destroyed the "tabernacle" and prohibited the practice; but the wells seem to have lost none of their reputation by the loss of their saint, and continued to be a favourite resort in the last part of the century. Their praises were sounded in 1572 by John Jones, "Phisition at the King's Mede, near Darby," in *The Benefits of the Ancient Baths of Buckstones*, and at a later period they were celebrated by Hobbes and Cotton in their respective accounts of the wonders of the Peak. See also Thomas Brown's *Tour in Derbyshire*, and among modern works, Sir Charles Scudamore's *Tepid Springs of Buxton*, 1839; Robertson's *Mineral Waters*, 1854; L. Jewitt's *History of Buxton*.

BUXTON, Jedediah, a prodigy of skill in numbers, was born in 1704, at Elmton, near Chesterfield in Derbyshire. Although his father was schoolmaster of the parish, and his grandfather had been the vicar, his education had been so neglected that he could not write; and his knowledge, except of numbers, was extremely limited. How he came first to know the relative proportions of numbers, and their progressive denominations, he did not remember; but on such matters his attention was so constantly rivetted, that he frequently took no cognizance of external objects, and when he did, it was only with reference to their numbers. He worked out every question after his own method, without any external aid, and without understanding the common rules of arithmetic. He would stride over a piece of land or a field, and tell the contents of it almost as exactly as if it had been measured by the chain. In this manner he measured the whole lordship of Elmton, consisting of some thousand acres, and gave the contents not only in acres, roods, and perches, but even in square inches. After this, for his own amusement, he reduced them into square hairs'-breadths, reckoning forty-eight to each side of the inch. His memory was so great, that in resolving a question he could leave off and resume the operation again at the same point after the lapse of a week, or even of several months. His perpetual application to figures prevented the smallest acquisition of any other knowledge. On his return from church it never appeared that he had brought away one sentence, his mind having been busied in his favourite occupation. His wonderful faculty was tested in 1754 by the Royal Society of London, who acknowledged their satisfaction by presenting him with a handsome gratuity. During his visit to the metropolis he was taken to see the tragedy of Richard III. performed at Drury Lane theatre, but his whole mind was given to the counting of the words uttered by Garrick. Similarly, he set himself to count the steps of the dancers; and he declared that the innumerable sounds produced by the musical instruments had perplexed him beyond measure. He lived till about the age of seventy, and died at the place of his birth.

BUXTON, Sir Thomas Fowell (1786–1845), a distinguished philanthropist, whose name is inseparably associated with that of Wilberforce in the abolition of slavery, was born in Essex, April 1, 1786. He was not educated at any of the public schools, and at about the age of eighteen he entered Trinity College, Dublin, with a very slender stock of acquirements. But he was aware of his defects, and laboured so earnestly that he came out one of the first men of his time, and with an extraordinarily high reputation as a speaker. In 1809 he married Harriet Gurney, sister of the celebrated Mrs Fry. As his own means were not of themselves sufficient to support his family, he entered in 1808 the brewery establishment of Truman, Hanbury, and Co., of which his uncles, the Hanburys, were partners. He devoted himself to business with characteristic enthusiasm, became a partner in 1811, and soon had the whole concern in his hands. In 1816 he brought himself into notice by his speech in behalf of the Spitalfields weavers, and in 1818 he published his able *Inquiry into Prison Discipline*. The same year he was elected member for Weymouth, a borough for which he continued to sit till 1837. In the House of Commons he had a high reputation as an able and straightforward speaker, devoted to philanthropic schemes. Of these plans the most important was that for the abolition of slavery in the British colonies. Buxton devoted his life to this object, and through defeat and opposition, despite the attacks of enemies and the remonstrances of faint-hearted friends, he remained true to it. Not till 1833 was he successful, and even then only partially, for he was compelled to admit some clauses against which his better judgment had decided. In 1837 he ceased to sit in the House of Commons. He travelled on the Continent in 1839 to recruit his health, which had given way, and took the opportunity of inspecting Continental prisons. He was made a baronet in 1840, and then devoted himself to a plan for ameliorating the condition of the African negroes. The failure of the Niger expedition was a blow from which he never recovered. He died on the 19th February 1845. (See *Memoir and Correspondence of Sir T. F. Buxton*, edited by his son, Charles Buxton, 1848.)

BUXTORF, or Buxtorff, John (1564–1629), the first of a line of distinguished scholars, whose Hebrew and rabbinical learning shed lustre upon the university of Basel during the 17th century, was born at Camen in Westphalia on the 25th December 1564. The original form of the name was Bockstrop, or Boxtrop, from which was derived the family crest or insignia, which bore the figure of a goat (*Bock* in German signifying "he-goat"). His early education was received at the schools of Hamm and Dortmund. After the death of his father, who was minister of Camen, Buxtorf resumed his studies, which had been interrupted for a short time by that event, at Marburg, and the newly-founded university of Herborn, at the latter of which Olevian and Piscator had been recently appointed professors of theology. It was under the teaching of Piscator that Buxtorf first imbibed a love for the Hebrew language and literature, that department in which he was destined afterwards to become so famous. So great was his progress in these studies, that Piscator acknowledged that he was far surpassed by his pupil. At a later date Piscator received the assistance of Buxtorf in the preparation of his Latin translation of the Old Testament, which was published at Herborn in 1602–3. From Herborn Buxtorf repaired to Heidelberg, and thence to Basel, to which latter university he was attracted by the reputation of John James Grynæus and Hospinian. After a residence of some time at Basel, Buxtorf proceeded to Zurich, for the purpose of attending the lectures of Bullinger, and after that to Geneva, where he enjoyed for a short time the instructions of Beza. On his return to Basel, Grynæus, who had been greatly impressed by the character, talents, industry, and great learning of the youth, and was desirous that the services of one who promised to become a scholar of great distinction should be secured to the university, procured him a situation as tutor in the family of Leo Curio, son of Cœlius Secundus Curio, so celebrated for his sufferings on account of the Reformed faith. This arrangement exercised a decisive influence upon the future life, public and private, of Buxtorf. At the instance of Grynæus, Buxtorf undertook the duties of the Hebrew chair in the university, and discharged them for two years with such ability and acceptance, that at the end of that time he was unanimously appointed to the vacant office. From this date (1590) to his death in 1629, a period of thirty-nine years, Buxtorf remained in Basel, and devoted himself to the study of Hebrew and rabbinical literature with an energy and zeal that have rarely been paralleled in the history of any scholar. He is said never to have devoted fewer than eight or ten hours daily to study. Not satisfied with perusing the works of the rabbins, he received into his own house many learned Jews, that he might discuss with them the more difficult and abstruse points treated of in the writings of their countrymen. So great, indeed, became his reputation for profound and extensive knowledge of rabbinical books, that he was frequently consulted by Jews themselves on matters relating to their ceremonial law. Probably no Protestant scholar ever possessed so complete a knowledge of the contents of the rabbinical writings as Buxtorf, and he

seems to have well deserved the title which was conferred upon him of "Master of the Rabbins." His partiality for Jewish society exposed him, indeed, on one occasion to considerable annoyance. He had received a Jew named Abraham into his house in order to assist him in the editing of his great Rabbinical Bible. Abraham's wife was confined of a boy, whose circumcision, agreeably to Hebrew usage, had to take place on the eighth day after birth, and it was necessary that at least two Jewish witnesses should be present at the ceremony. Buxtorf obtained permission from the chief officer of the town council to allow two Jews from a distance to assist on the occasion, while he himself, his son-in-law, and two citizens of Basel, were also present. This proceeding, however, gave great offence to the authorities of the city, the laws against the Jews being at this time exceedingly stringent. The result was that Buxtorf and his son-in-law were each fined 100 florins, the father of the boy 400 florins, while the officer of the municipality and the two citizens were punished with three days' imprisonment. Notwithstanding this occurrence, however, Buxtorf's relations with the city of Basel were of a friendly kind. He remained firmly attached to the university which first recognized his merits, and declined two invitations which were offered him, from Leyden and Saumur successively, to fill the Hebrew chair in these famous schools. His correspondence with the most distinguished scholars of the day was very extensive, and in the rich collection of letters preserved in the library of the university of Basel, are contained materials for a literary history of the time which it is hoped may be one day utilized.

The works which Buxtorf published during his life are too numerous to be all enumerated in this brief notice, and for a complete list of them the reader is referred to the authorities cited at the close of the article. The following, however, may be mentioned. In 1602 appeared his *Manuale Hebraicum et Chaldaicum*, which reached a seventh edition in the year 1658. In the following year was published his *Synagoga Judaica*, which appeared first in German and was afterwards translated into Latin in an enlarged form, and which constitutes a valuable repertory of information regarding the opinions and ceremonies of the Jews. In 1607 he published his *Lexicon Hebraicum et Chaldaicum cum brevi Lexico Rabbinico Philosophico*, which was reprinted at Glasgow so recently as 1824. In 1618 there appeared in two folio volumes his great *Rabbinical Bible*, containing, in addition to the Hebrew text, the Chaldee Paraphrases or Targums, which he punctuated after the analogy of the Chaldee passages in Ezra and Daniel (a proceeding which has been condemned by Richard Simon and others), and the Commentaries of the more celebrated Rabbins, with various other treatises. Of this work it may be said that Rosenmuller's judgment will approve itself to most Hebrew scholars,—that "this edition is indispensable to every one who desires thoroughly to study the criticism and exposition of the Old Testament."—(Rosenmuller, *Handbuch für die Literatur der Biblischen Kritik und Exegese*, vol. i. p. 259). The Bible was followed by his *Tiberias, sive Commentarius Masoreticus*, so named from the great school of Jewish criticism which had its seat in the town of Tiberias. It was in this work that Buxtorf controverted the views of Elias Levita regarding the late origin of the Hebrew vowel points, a subject which gave rise to the famous controversy between Cappellus and his son John Buxtorf, which will be referred to in the following article. Buxtorf did not live to complete the two works on which his reputation chiefly rests, viz., his great *Lexicon Chaldaicum, Talmudicum, et Rabbinicum*, and the *Concordantiæ Bibliorum Hebraicorum*, both of which were edited by his son. They are monuments of untiring labour and industry, and possess an enduring value. The former work has been recently (1869) republished at Leipsic with some additions by Bernard Fischer, Ph.D., and the latter was assumed by Fürst as the basis of his great Hebrew concordance, which appeared in 1840. For additional information regarding his writings the reader is referred to *Athenæ Rauricæ*, pp. 444–448; to the article "Buxtorf" in Ersch and Gruber's *Encyclopædia*; to the *Theological Cyclopædias* of Herzog, and of Wetzer and De Welte, *sub voce* "Buxtorf"; to Niceron's *Memoires*, vol. xxxi. pp. 206–215; to Schrokh's *Kirchengeschichte*, vol. v. (Post-Reformation period) pp. 72 *sq.*, Leipsic, 1806; and to Meyer's *Geschichte der Schrift-Erklarung*, vol. iii., Göttingen, 1804. (F. C.)

BUXTORF, or BUXTORFF, JOHN (1599–1664), commonly called "junior," to distinguish him from his father, the subject of the preceding notice. He was born at Basel on the 13th August 1599, and at a very early age displayed remarkable aptitude for the acquisition of languages. When only four years old he was sent to school, at which age he is said to have been able to read Latin, Greek, and Hebrew, in which he had been instructed by his father. At the age of twelve he entered the university, where he speedily distinguished himself above not only his equals, but his seniors in years, to so great a degree that when only sixteen he received the diploma of master of arts from the hands of his own father. From this time he devoted himself to the study of theology, turning his attention especially to the Hebrew language and its cognate dialects, and then proceeding to the study of rabbinical Hebrew, in which he soon attained such proficiency, that he is said, while still a young man, to have read through not only the Mishna, but also the Jerusalem and Babylonian Gemaras, or commentaries upon the text of the Talmud. In conformity with the excellent custom, so long prevalent on the Continent, of visiting several universities before finally settling down to life-long professional work, Buxtorf proceeded to Heidelberg in 1617, where he listened to the prelections of the theologians Pareus, Scultetus, and the elder Alting. In 1619 he repaired to Dort, while the famous Synod was still sitting, and there made the acquaintance of many of the divines who took part in its proceedings. At the close of the Synod he made a short journey in company with the deputies from Basel, through the Netherlands and England, and thence through France back to Basel. On his return he found that his father's great Rabbinical Bible was in course of publication, and as there was no lexicon suitable for the study of the Chaldee Targums, comprised in the work, he undertook the compilation of such a lexicon, which appeared at Basel in 1622 under the title of *Lexicon Chaldaicum et Syriacum*, with a recommendatory preface from his father, detailing the circumstances under which the work had been executed. Still thirsting for knowledge, he repaired in 1623 to Geneva, to enjoy the instructions of the elder Turretin, Diodati, and Tronchin; while in return Turretin and Dav. Clericus did not disdain to avail themselves as pupils of his pre-eminent knowledge of Hebrew and of the rabbinical dialect. So great by this time had become his reputation as a scholar, that he was offered by the authorities of the city of Bern the chair of logic at Lausanne, which he declined, preferring to return to Basel, where in 1624, he was appointed general deacon to the church of Basel (*Communis Ecclesiæ Basileensis Diaconus*), and three years later deacon of St Peter's church. On the death of his father in 1629, Buxtorf was unanimously designated as the fittest person to succeed so distinguished a Hebraist; and by the advice of his physicians, who were of opinion that the labours involved in the discharge of the duties of a public preacher would be injurious to one whose constitution was feeble, he finally accepted the office. From this date until his death he remained at Basel, declining two offers which were made to him from Groningen and Leyden, to accept the Hebrew chair in these two celebrated schools. To mark their appreciation of his patriotic conduct, the governing body of the university founded in 1647, specially for his behoof, a third theological professorship, that of "Commonplaces and Controversies," the duties of which Buxtorf discharged for seven years along with those of the Hebrew chair. When, however, the professorship of the Old Testament became vacant in 1654 by the death of Theodore Zuinger, Buxtorf resigned the chair of theology, and accepted that of the Old Testament instead, holding both offices, and for some time that also of chief librarian to the university, until his death in 1664. The course of his private life was chequered by many domestic bereavements. He was four times married,

his three first wives dying shortly after marriage, and the fourth predeceasing her husband by seven years. His children also all died young, with the exception of two boys, the younger of whom, John James, became first his father's colleague, and shortly after his successor in the chair of Hebrew.

A considerable portion of his public life was spent in controversy regarding disputed points in Biblical criticism, in reference to which he had to defend the views advanced by his father. The attitude of the Reformed churches at that time, as opposed to the Church of Rome, led them to take up and maintain many opinions in regard to Biblical questions, which were not only erroneous in point of fact, but which were altogether unnecessary for the stability of their position. Having renounced the dogma of an infallible church, it was deemed necessary to maintain as a counterpoise, not only that of an infallible Bible, but, as the necessary foundation of this, of a Bible which had been handed down from the earliest ages to the present time without the slightest alteration or change in its text. The letters in which the Old Testament was written, were, it was asserted, the same as those in which the two tables of the law had been written; the vowel points and accents which accompanied them had been given by divine inspiration; and the words themselves had not undergone the slightest change from the time they had flowed from the pens of the respective writers. The Masoretic text of the Old Testament, therefore, as compared either with that of the recently discovered Samaritan Pentateuch, or of the Septuagint, or of the Vulgate, was alone the "Hebrew Verity," wherein the true words of the sacred writers were to be found. Although many of the Reformers, as well as learned Jews, had long seen that these assertions could not be made good, there had been as yet no formal controversy upon the subject. It was reserved for a learned and acute Frenchman, Ludovicus Cappellus the younger, professor of Hebrew at Saumur, to enter the field, and by a series of controversial writings effectually to dispel the illusions which had long prevailed in many minds. As early as 1622 or 1623, Cappellus had submitted in manuscript to the elder Buxtorf a work on the modern origin of the vowel points and accents, which he had been led to undertake in consequence of the statements made by the Swiss professor in his *Tiberias*, or *Commentary on the Masora*, in which he had controverted the views of Elias Levita on the *late* origin of the points. Buxtorf saw the force of the arguments employed by Cappellus, but counselled him not to publish his work, pointing out the injury which it would do to the Protestant cause, and the advantage which it would afford to Romish controversialists on the question of the infallible accuracy of the text of Scripture. Cappellus, however, was not to be deterred by fear of consequences. He sent his MS. to Thomas Erpenius of Leyden, the most learned Orientalist of his day, by whom it was published in 1624, under the title *Arcanum Punctationis revelatum*, with a laudatory preface, but without the author's name. In this work Cappellus adduced those arguments and considerations which have satisfied most scholars since his day that the vowels and accents are the invention of the Masoretes, and that they are not older than the fifth century of the Christian era. It is worth noting that although the elder Buxtorf lived five years after the publication of the work, he made no public reply to it, and it was not until 1648, nearly a quarter of a century afterwards, that Buxtorf, junior, published his *Tractatus de punctorum origine, antiquitate, et authoritate, oppositus Arcano punctationis revelato Ludovici Cappelli*. In this treatise he endeavoured to prove by copious citations from the rabbinical writers, and by arguments of various kinds, that the points, if not so ancient as the time of Moses, were at least as old as that of Ezra, and thus possessed the authority of divine inspiration. In the course of the work he allowed himself frequently to employ contemptuous epithets towards Cappellus, such as "innovator," "prophet," "revealer," "a seer of visions," "dreams," &c. Cappellus was not the man to remain silent in such circumstances. He speedily prepared a second edition of his work, in which, besides replying to the arguments of his opponent, and fortifying his position with new ones, he retorted his contumelious epithets with interest. Owing to various causes, however, among which may be mentioned the distrust with which Cappellus was coming to be regarded on account of his critical opinions among Protestants themselves, this second edition did not see the light until thirty years after his death, when it was published at Amsterdam in 1685, in the edition of his collected works. Besides this controversy, Buxtorf engaged in three others with the same antagonist, on the subject of the integrity of the Masoretic text of the Old Testament, on the antiquity of the present Hebrew characters, and on the Lord's Supper. Into the details of these, however, our space does not allow us to enter. In the two former Buxtorf supported the untenable position that the text of the Old Testament had been transmitted to us without any errors or alteration, and that the present square or so-called Chaldee characters were coeval with the original composition of the various books. These views were triumphantly refuted by his great opponent in his *Critica Sacra*, and in his *Diatriba de veris et antiquis Ebraicorum literis*. Besides the works which have been already mentioned in the course of this article, Buxtorf edited the great *Lexicon Chaldaicum, Talmudicum, et Rabbinicum*, on which his father had spent the labour of twenty years, and to the completion of which he himself gave ten years of additional study, and the great Hebrew *Concordance*, which his father had little more than begun. In addition to these, he published new editions of many of his father's works, as well as others of his own, complete lists of which may be seen in the *Athenæ Rauricæ*, and other works enumerated at the close of the preceding article. (F. C.)

BUZZARD, a word derived from the Latin *Buteo*, through the French *Busard*, and used in a general sense for a large group of Diurnal Birds-of-prey, which contains, among many others, the species usually known as the Common Buzzard (*Buteo vulgaris*, Leach), though the English epithet is now-a-days hardly applicable. The name Buzzard, however, belongs quite as rightfully to the birds called in books "Harriers," which form a distinct subfamily of *Falconidæ* under the title *Circinæ*, and by it one species, the Moor-Buzzard (*Circus æruginosus*), is still known in such places as it inhabits. "Puttock" is also another name used in some parts of the country, but perhaps is rather a synonym of the Kite (*Milvus ictinus*). Though ornithological writers are almost unanimous in distinguishing the Buzzards as a group from the Eagles, the grounds usually assigned for their separation are but slight, and the diagnostic character that can be best trusted is probably that in the former the bill is decurved from the base, while in the latter it is for about a third of its length straight. The head, too, in the Buzzards is short and round, while in the Eagles it is elongated. In a general way Buzzards are smaller than Eagles, though there are several exceptions to this statement, and have their plumage more mottled. Furthermore, most if not all of the Buzzards, about which anything of the kind is with certainty known, assume their adult dress at the first moult, while the Eagles take a longer time to reach maturity. The Buzzards are fine-looking birds, but are slow and heavy of flight, so that in the old days of falconry they were regarded with infinite scorn, and hence in common English to call a man "a buzzard" is to denounce him as stupid. Their food consists of small mammals, young birds, reptiles, amphibians, and insects,—particularly beetles,—and thus they never could have been very injurious to the game-preserver, though they have fallen under his ban, if indeed they were not really his friends, but at the present day they are so scarce that in this country their effect, whatever it may be, is inappreciable. Buzzards are found over the whole world with the exception of the Australian region, and have been split into many genera by systematists. In the British Islands we have two species, one resident (the *B. vulgaris* already mentioned), and now almost confined to a few wooded districts; the other the Rough-legged Buzzard (*Archibuteo lagopus*), an irregular winter-visitant, sometimes arriving in large bands from the north of Europe, and readily distinguishable from the former by being feathered down to the toes. The Honey-Buzzard (*Pernis apivorus*), a summer-visitor from the south, and breeding, or attempting to breed, yearly in the New Forest, does not come into the subfamily *Buteoninæ*, but is probably the type of a distinct group, *Perninæ*, of which there are other examples in Africa and Asia. (A. N.)

BYNG, GEORGE (1663–1733), Viscount Torrington, a distinguished English admiral, was born at Wrotham, Kent, and at the age of fifteen went to sea as a volunteer. After being several times advanced, he was in 1702 raised to the command of the "Nassau," a third rate, and was at the taking and burning of the French fleet at Vigo; and the next year he was made rear-admiral of the red. In 1704 he served in the grand fleet sent to the Mediterranean, under Sir Cloudesley Shovel, as rear-admiral

of the red, and reduced Gibraltar. He was in the battle of Malaga, which followed soon afterwards, and for his gallantry in that action received the honour of kinghthood. In 1718 he was made admiral and commander-in-chief of the fleet, and was sent with a squadron into the Mediterranean for the protection of Italy. This commission he executed so well that the king made him a handsome present, and sent him full powers to negotiate with the princes and states of Italy, as there should be occasion. He procured the emperor's troops free access into the fortresses which still held out in Sicily, sailed afterwards to Malta, and brought out the Sicilian galleys, and a ship belonging to the Turkey Company. By his advice and assistance the Germans retook the city of Messina in 1719, and destroyed the ships which lay in the basin—an achievement which completed the ruin of the naval power of Spain. The Spaniards being much distressed offered to quit Sicily; but the admiral declared that the troops should never be suffered to depart from the island till the king of Spain had acceded to the quadruple alliance, and to his conduct it was entirely owing that Sicily was subdued, and the king forced to accept the terms prescribed him by the alliance. On his return to England he was made rear-admiral of Great Britain, a member of the privy council, Baron Byng of Southill, in the county of Bedford, and Viscount Torrington in Devonshire. He was also made one of the Knights Companions of the Bath upon the revival of that order in 1725. In 1727 George II., on his accession to the crown, placed him at the head of naval affairs as first lord of the Admiralty. He died January 15, 1733, in the seventieth year of his age, and was buried at Southill, in Bedfordshire.

BYNG, The Hon. John (1704–1757), British admiral, fourth son of the subject of the preceding notice, entered the navy at an early age, became captain in 1727, and in 1745 was made rear-admiral of the red. In the year 1755 the British Government received intimation that the French were fitting out a naval expedition in Toulon, and it behoved them to attend to the defences of Gibraltar and Minorca. Nothing, however, was done until the intentions of the French were too apparent, and Byng was then entrusted with ten miserably equipped ships of war, and set sail from Spithead on the 7th April 1756. He put in at Gibraltar to receive stores, and there learnt that the French had made good their descent upon Minorca. On the 19th May he came in sight of St Philip's, still held by the British, but failed to establish communications with the governor. On the following day he engaged with the French fleet, which was inferior in number of vessels, but vastly superior in armament and equipment. There seems no doubt that the division under Byng's charge did not second with sufficient eagerness the bold attack made by Admiral West. The action was indecisive, and next morning Byng called a military council, and it was resolved that, under the circumstances, it was hopeless to attempt anything further, and that Minorca must be left to its fate. The fleet returned to Gibraltar. The indignation of the English at the transaction was intense, and the Government took advantage of it to avert from themselves the charge of incapacity. Byng was at once superseded and brought home under arrest. A court-martial on his conduct sat during December 1756 and January 1757, and found that the admiral had not done his utmost to relieve St Philip's, or to defeat the French fleet, though they fully acquitted him of cowardice or treachery. The only punishment open to them to inflict was that of death, and they passed their sentence with the utmost reluctance, coupling it with an earnest recommendation to mercy. No attention was paid to this or to other attempts to mitigate what was felt to be an unduly severe punishment for mere incapacity. The unfortunate admiral was shot on the 14th March 1757.

BYNKERSHOEK, Cornelius Van (1673–1743), a distinguished Dutch jurist, was born at Middleburg in Zeeland. In the prosecution of his legal studies, and while holding the offices first of member and afterwards of president of the supreme court, he found the common law of his country so defective as to be nearly useless for practical purposes. This abuse he resolved to reform, and took as the basis of a new system the principles of the ancient Roman law. His works are very voluminous. The most important of them are the *Observationes Juris Romani*, published in 1710, of which a continuation in four books appeared in 1733; the treatise, *De Dominio Maris*, published in 1721; and the *Quæstiones Juris Publici*, published in 1737. Complete editions of his works were published after his death; one in folio at Geneva in 1761, and another in two volumes folio at Leyden in 1766.

BYROM, John (1691–1763), a poet and miscellaneous writer, was born at Kersall, near Manchester, and educated at Trinity College, Cambridge. His first poetical essay, the well-known *Colin and Phœbe*, appeared in the *Spectator*, No. 603. After leaving the university he studied medicine at Montpellier, and became a convert to the mystical theology of Bourignon and Boehme. He was elected a member of the Royal Society in 1723. Having reduced himself to narrow circumstances by a precipitate marriage, he supported himself by teaching a new method of shorthand writing, of his own invention, till he succeeded to an estate on the death of an elder brother. He was a man of lively wit, of which, as opportunity offered, he gave many specimens. A collection of his miscellaneous poems was printed at Manchester, in two vols. 8vo, 1773, and reprinted at Leeds in 1814, with a life of Byrom by an anonymous writer. Byrom's *Private Journal and Correspondence* have appeared among the publications of the Chetham Society (vols. xxxiv. and xliv.)

BYRON, George Gordon Noel Byron, Lord (1788–1824). The portrait of the most remarkable figure in the literature of this century is still too often made up on the principle of putting in all the shadows and leaving out all the lights. Not only the facts of his own life, but even the records and traditions of his ancestry, are partially selected in this way. It is true, no doubt, that a man's immediate ancestors must be supposed to have most influence on his character, and that Byron's immediate ancestors were far from being quiet, respectable people. His father, Captain Byron, was a profligate officer, whose first wife was a divorced lady with whom he had eloped to France, who married a second time only to find the means for paying his debts, and who left his wife as soon as her fortune was exhausted. His mother, Catherine Gordon, heiress of Gight in Aberdeenshire, was a fitful and passionate woman, who knew no stable halting-place between the extremes of indulgent fondness and vindictive disfavour. His grand-uncle, whom he succeeded in the title, had killed his neighbour and relative, Mr Chaworth, in a drunken brawl, had been tried before the House of Lords on the charge of murder and acquitted, but had been so wrought upon by remorse and the sense of public opprobrium, that he shut himself up at Newstead, let the place go to ruin, and acquired such a bad repute by his solitary excesses that he was known as the "wicked Lord Byron." Even in this wild ancestry it is easy to detect the corruption of good things. In other parts of the family line the nobler elements are seen running clear and pure. The poet's grandfather, Admiral Byron, "Foul-weather Jack," who had as little rest on sea as the poet on land, had the virtues without the vices of the race. Farther down the family tree we find the Byrons distinguishing themselves in the field. Seven brothers fought in the

battle of Edgehill. None of the family would seem to have been stirred by the poetic impulse in the brightest period of English song, but later on, under Charles II., there was a Lord Byron who patronized literature, and himself wrote some verses in which he professed—

> "My whole ambition only doth extend
> To gain the name of Stedman's faithful friend."

Sir Egerton Brydges, however, has found a poetic ancestry for Byron by connecting the Byrons of the 17th century with the family of Sydney.

The poverty into which Byron was born, and from which his accession to high rank did not free him, had much to do in determining his future career. That he would have written verses in whatever circumstances he had been born we may safely believe; but if he had been born in affluence we may be certain that, with his impressionable disposition, he would never have been the poet of the Revolution—the most powerful exponent of the modern spirit. By the time of his birth (at Holles Street, London, January 22, 1788), his father had "squandered the lands o' Gight awa," and his mother was on her way back from the Continent with a small remnant of her wrecked fortune. Mrs Byron took up her residence in Aberdeen; and her "lame brat," as she called him in her fits, was sent for a year to a private school at 5s. a quarter, and afterwards to the grammar school of the town. Many little stories are told of the boy's affectionate gratitude and venturesome chivalry, as well as of his exacting and passionate temper. The sisters Gray, who were his successive nurses, found him tractable enough under kind treatment. His mother, whose notions of discipline consisted in hurling things at him when he was disobedient, had no authority over him; he met her violence sometimes with sullen resistance, sometimes with defiant mockery; and once, he tells us, they had to wrench from him a knife which he was raising to his breast. At school he passed from the first to the fourth class, but with all his ambition to excel he was too self-willed to take kindly to prescribed tasks, too emotional for dry intellectual work; and he probably learned more from Mary Gray, who taught him the Psalms and the Bible, than he did from his schoolmaster. Before he left Aberdeen, which he did on the death of his grand-uncle and his accession to the peerage in May 1798, he gave a remarkable proof of the precocious intensity of his affections by falling in love with his cousin Mary Duff. So strong a hold did this passion take of him, that six years afterwards he nearly went into convulsions on hearing of her marriage.

When Byron's name was first called in school with the prefix "Dominus," the tradition is that he burst into tears,—from pride, M. Taine conjectures,—from pain at the gulf thus placed between him and his school-fellows, the Countess Guiccioli. Soon after, his mother, who had frequently taken advice for the cure of his lame foot, went with him to Nottingham, and placed him under the care of an empiric, who tortured him to no purpose. The torture was renewed under the advice of a London physician at Dr Glennie's school at Dulwich, at which he was entered in the summer of 1799; and at last the foot, as he wrote to his old Scotch nurse, was so far restored that he was able to put on a common boot. He was two years with Dr Glennie, and though he made little progress in his classical studies, he had the run of his master's library, and added greatly to his general information. Before he left for Harrow he had contracted another passion for his cousin Margaret Parker, so intense that he could not sleep nor eat when he was looking forward to meeting her. He went to Harrow in 1801, "a wild northern colt," as the head-master said of him, very much behind his age in Latin and Greek. This deficiency he never quite overcame, though he worked enough to get into the same form with boys of his own age. Antiquarian studies never had any charm for him. But though, according to his own account, he was always cricketing, rebelling, and getting into mischief, his brain was not idle. Partly to keep up his school repute for "general information," he read every history he could lay hands on, and not without system either, for he set himself deliberately to know something about every country. He also went through all the British classics, both in Johnson and in Anderson, and most of the living poets. Few boys left Harrow with such a store of useful learning. Many anecdotes are told of the warmth of his friendships at Harrow, and his chivalry in defending his juniors. In the vacation of 1803 he again fell in love—this time more seriously—with Miss Chaworth, whose grandfather "the wicked Lord Byron" had killed. In the melancholy moods of his after life her rejection of him was often a subject of passionate regret.

Byron's residence at Cambridge (Trinity College, 1805 to 1808, with interval of a year) added little to his knowledge of academical learning. The arts in which he qualified himself to graduate were swimming, riding, fencing, boxing, drinking, gaming, and the other occupations of idle undergraduates. When he went up to Cambridge he was wretched, he tells us, partly from leaving Harrow, partly "from some private domestic circumstances of different kinds," chiefly, it may be presumed, the want of money; but his friend Scrope Davies lent him large sums, and he lived with a certain reckless happiness which had a great deal more to do with his moodiness and melancholy than the libertine excesses with which he is popularly credited. Much more important than his residence in Cambridge, as bearing on his mental development, was his year's residence at Southwell. From that happy period, which saw the serious dawn of his genius, M. Taine has picked out only the unhappy violent quarrel with his mother, which was the cause of its termination. His intimacy with the Pigotts, and the expansion of his poetic impulses under their genial encouragement, are much more worthy of notice than this culmination of miserable bickerings which he was now strong enough to laugh at, when the domestic storm was over. He had scribbled many verses at Harrow, but had been too shy to show them to his roystering friends; and now finding for the first time an admiring audience, he put forth his powers in earnest, as he could do only under the influence of love or defiance. The result came before the public in the *Hours of Idleness*, published by Ridge of Newark in March 1807.[1] The poems in that collection have something of the insipidity of the circumstances that gave them birth, but the fact of publication bound him to his vocation to a degree of which he was not at all aware. Hitherto his ambition had pointed towards politics as his natural field, and he said as much in the somewhat disdainful preface to his poems. Putting his ambition into verse, he characteristically compared himself to a slumbering volcano, and longed to burst on the world as a Fox or a Chatham. But the *Hours of Idleness* decided his career for him. When he went back to Trinity College he could not help eagerly watching their effect. Again and again he wrote to the friendly Miss Pigott to hear how they were succeeding. He was prepared for defeat, he said, and he promised to take vengeance on adverse critics. He was made a new man by the publication; he had tasted public applause and hungered for more of it. It was then that he carefully examined himself, and took stock of his acquirements in the very remarkable document dated

[1] He had previously printed a volume for private circulation, and it is characteristic of his docility, under gentle influences, that he burnt the first impression when Mr Becher rebuked him for the too warm colouring of one of the poems.

November 30, 1807, to which we are indebted for our knowledge of the extent of his studies. In the midst of his rollicking set at Cambridge he was secretly girding up his loins, and collecting his powers to make a grand struggle for fame. Perhaps no poet was ever drawn out so directly by the thirst for public honour; no poet ever appealed so directly to the public eye and heart. He launched himself bodily before the world, almost ravenous for sympathy and homage.

It is generally said that but for the savage attack of the *Edinburgh Review* in the spring of 1808 Byron might never have returned to poetry. But the fact is that the review did not appear till a year after the publication of *Hours of Idleness*, and in the interval Byron, for all his farewell to poetry, was "scribbling," as he called it, more furiously than ever. "I have written," he wrote to Miss Pigott, six months before the Edinburgh attack, "214 pages of a novel; one poem of 380 lines, to be published (without my name) in a few weeks with notes; 560 lines of *Bosworth Field*, and 250 lines of another poem in rhyme, besides half a dozen smaller pieces. The poem to be published is a satire." This satire was the poem which he afterwards converted into a reply to the *Edinburgh Review*. He anticipated censure, and fore-armed himself—always as eager to defy reproof as he was to win applause. Apparently he put off publishing his satire till all his critics should have had their say, and he should know clearly where to hit. When the attack came it wounded him bitterly; but a friend who called on him at the time thought from the fierce light in his eye that he had received a challenge. He was in no hurry to publish; he worked at leisure, with a confident consciousness of his powers, and *English Bards and Scotch Reviewers* did not make its appearance till the spring of 1809. When it did appear the authorship was soon discovered, and it was the talk of the town. To us who look back upon it dispassionately, and compare its somewhat heavy and mechanical couplets with the exquisite lightness and fitting-point of its antitype the *Dunciad*, the satire appears to possess no great force; but the personalities told at the time, when there was a vague unrest in the literary world at the outspoken severity and sometimes truculent malice of the Scotch review, and the injured poet had his revenge in a general acknowledgment that the objects of his wrath deserved castigation, and that the lash was well laid on.

Soon after the publication of his satire, Byron, in June 1809, left for his travels on the Continent; and one would have expected that the young lord, with the wreath of triumph still fresh on his head after his first literary battle, would have gone on his journey with satisfaction and hopeful curiosity. He sailed in deep dejection, with all the bitterness of a man who feels himself friendless and solitary, and he returned after two years' wandering in Spain, Albania, Greece, Turkey, and Asia Minor, sadder than before. Why was this? Those who identify him with his own Childe Harold, are ready with the answer that he had lived a life of dissolute pleasure, and was already, at the age of twenty-one, experiencing the pains of satiety and exhaustion. But this is not borne out by such scanty light as he and his friends have thrown on his life at this period. He himself always protested, both in public and private, against being identified with Childe Harold. Childe Harold's manor was an old monastic residence; he left his country in bitter sadness; in the original MS. his name was Childe Burun; he left behind him a mother and a sister; and he passed through the scenes of Byron's travels. But there the resemblance ends. The resemblance is really confined, as the author alleged, to local details. There is no reason to disbelieve what the author affirmed, that Childe Harold was a purely fictitious character, "introduced for the sake of giving some connection to the piece." To make him what he intended—"a modern Timon, perhaps a poetical Zeluco,"—the poet drew, no doubt, upon his own gloomier moods; he felt occasionally as he makes Harold feel habitually, but the process was much more dramatic than the world, in spite of his protests, took for granted. Byron, with all his bitter moods of forlorn despondency, was too susceptible a spirit to "stalk in joyless reverie" through the south of Europe, as his letters home testify. And we know that his picture of the Bacchanalian feasts in the monastery, with "Paphian girls," and "flatterers and parasites," is not at all like what actually occurred at Newstead Abbey. There were no "laughing dames" there, except the domestics, and the flatterers and parasites were his bosom friends whom he loved with a romantic ardour. They held "high jinks" there as any young men might have done, masqueraded about in monkish habits to be in whimsical conformity with the place, practised pistol-shooting in the old hall, had a wolf and a bear chained at the entrance, had the garden dug up in search of concealed treasure, found a skull there, had it made into a cup, and passed this cup round after dinner, with the conceit that their mouths did it less harm than the worms, and that when its wit had ceased to sparkle, it had better be filled with Burgundy to make other wits sparkle than lie rotting in the earth. Byron himself was too poor, as Moore has remarked, to keep a harem, had such been his wish. He is known to have had a romantic passion for a girl who used to travel with him in England in boy's clothes; but whoever thinks he was satiated with this poor creature's devotion to him, should read the concluding stanzas of the second canto of *Childe Harold*, where the poet speaks in his own person, and laments her death in language utterly out of keeping with the dark unfeeling mood of his "modern Timon." One can then understand why he should have said that "he would not for worlds be a man like his hero." There is really very little of the personage Childe Harold in the poem; the poet simply has him by his side as a connecting link, while he describes the scenes through which he passed. In the two last cantos, indeed, Byron, angry that the public had identified him with Childe Harold, and then more defiant of public opinion, hardly cared to keep up the separation between his own character and the pilgrim's; and in the last canto he avowedly makes them coalesce.

To look for the causes of moodiness and melancholy in material circumstances is a very foolish quest; but we may be certain that insufficiency of this world's money, and the daily vexations and insults to which his rank was thereby exposed, had much more to do with Byron's youthful gloom than satiety of this world's pleasures. His embarrassed finances, and the impossibility of securing the respect due to his title, formed a constant source of annoyance, put his whole system into a morbid condition, in which every little slight and repulse festered and rankled with exaggerated virulence. From the daily humiliations and impertinences to which his false position exposed him, aggravated by his jealous and suspicious irritability, he may have turned sometimes to Childe Harold's consolations—"the harlot and the bowl," but his nature prompted him rather to forget his vexations in purer and worthier objects. Unfortunately for him, such impetuous and passionate affections as his could rarely find the response for which he craved. In those few cases where devotion was repaid with devotion, the warmth of his gratitude was unbounded; he loaded poor Thyrza's memory with caresses, careless of what the world might say, remembering only that the poor girl clung to him with unselfish love; and he returned his sister's tender regard with an ardour and constancy that showed how highly he prized and how eagerly he reciprocated

sincere affection. Circumstances that would have fallen lightly on a less sensitive man preyed upon his self-torturing spirit. In his dejection he had taken pleasure in the romantic notion of collecting the portraits of his friends, and one of them refused to sit on the ground that he could not afford it. Another friend, invited to say good-bye, excused himself on the ground that he had to go shopping with his mother. Another prop on which he leaned also precipitated him into the Slough of Despond. His ambition pointed to political distinction, and having given fair youthful proof of the power he felt to be in him, his pride taught him to look for a warm welcome from his party chiefs when he came of age, but on the contrary, there was a haggle over his admission. Lord Carlisle held coldly aloof, and he had to wait with savage indignation till the marriage certificate of his grandfather was fished up in Cornwall before he could take his seat. This cold but perfectly correct and formal indifference added another pang to the bitterness with which he took leave of his country. When after two years' absence he returned, still dogged by impecuniosity and the incivilities, real and imagined, that follow in its train, he "found fresh cause to roam." Nursed as he had been in superstitions, he could hardly keep from crying out that the stars had combined against him, when in the months following his return friend after friend went to the grave. Matthews was drowned in the Cam; Wingfield died of fever at Coimbra; and he heard of both deaths on the same day. His mother died in the same month, and in spite of all their quarrels, he felt the bereavement bitterly.

But the death which most deeply wounded him came later. Nothing ever racked him with sharper anguish than the death of her whom he mourned under the name of Thyrza. To know the bitterness of his struggle with this sorrow, we have only to look at what he wrote on the day that the news reached him (October 11, 1811); some of his wildest and most fiercely misanthropical verse, as well as some of his sweetest and saddest, belongs to that blackest of dates in his calendar. It is time that something were done to trace this attachment, which has been strangely overlooked by the essayists and biographers, because it furnishes an important clue to Byron's character, and is, indeed, of hardly less importance than his later attachment to the Countess Guiccioli. Mr John Morley, in an essay which ought to be read by everybody who wishes to form a clear idea of Byron's poetry as a revolutionary force in itself and an index to the movement of the time, remarks upon the respect which Byron, with all his raillery of the married state in modern society, still shows for the domestic idea. It is against the artificial union, the marriage of convenience, that Byron's raillery is directed; he always upholds singleness of attachment as an ideal, however cynically or mournfully he laments its infrequence, and points with laughter or with tears at the way in which it is crossed and cut short by circumstances when it does exist. Byron is not a railer against matrimony, except as a counterfeit of the natural union of hearts. His attachment to Thyrza shows that in this, as in other matters, he was transparently sincere. It is commonly taken for granted that his youth before, and, indeed, after his marriage with Miss Milbanke, was a featureless level of promiscuous debauchery; but those who look more narrowly into the facts cannot fail to see that, whatever may have been the number of his "light of loves,"—his fugitive passions were innumerable,—and however often he may have lapsed into vulgar rakery in bitter despair or reckless wantonness, he was always pining for some constant love, and cursing the fate that had denied it to him. This purer sentiment was always enshrined in his heart of heart, from his boyhood to the end of his days. Who Thyrza was can probably never be known, but in trying to convey the impression that she was merely imaginary, probably with the intention of shielding his friend's memory, by declaring him innocent of a relationship unsanctioned by society, Moore really did Byron an injustice. The poor girl, whoever she was, and however much she was deified after her death by his imagination, would really seem to have been his grand passion. Her "dear sacred name" his hand, he says years afterwards, would have trembled to write; he wished it to "rest ever unrevealed;" and when he was questioned by the Countess Guiccioli, he was deeply agitated, and begged her not to recur to the subject. We find him in his *Journal*, with her in his memory, writing with contempt of the amours of some of his acquaintances, and scoffing at the idea of their applying the name of love to favours that could be purchased. She is the presiding genius of his series of *Eastern Tales;* he has recorded the fact that when he drew the portrait of Zuleika his whole soul was full of her memory, and her image was again before him when he described the relationship between Zara and the disguised Gulnare. Conrad, with all his conscious villany, had one redeeming passion—"love unchangeable, unchanged." The Giaour, too, loved but one; he learnt that lesson, he said, from the birds; he despised "the fool still prone to range," and "envied not his varied joys." All these portraitures of single-hearted devotion are tributes to the memory of Thyrza, the "more than friend," commemorated in the second canto of *Childe Harold.* Medora's song in the *Corsair,* "Deep in my soul that tender secret dwells," though not flawless as a lyric, is one of his most beautiful expressions of this mournful sentiment in a subdued key. When we realize how bitterly he lamented her death, and how he could not even bear to write her name, there seems some reason for believing that the mysterious object of Manfred's love and remorse is another of the forms that she took in his imagination. Whoever cares to look into the matter will find many little corroborative particulars. It is quite in keeping with the morbid self-accusing tendency, the exaggerated moral sensibility, which Byron showed all his life through, that he should have been consumed with remorse at a recollection which colder-hearted men of the world bear about with them every day without a pang.

For some months after his return to England, Byron lived at Newstead very unhappily. He wrote that he was growing nervous, "really, wretchedly, ridiculously, fine-ladically nervous." He could not arrange his thoughts; he feared his brain was giving way, and it would end in madness. He felt at times a strange tendency to mirth. Sometimes he thought of seeking relief in a warfare against society, and he besought one of his friends, when he heard of his deepening crimes, to remember the cause. The inconsistency between this hunger for sympathy and the reckless ferocity of the resolution, shows how distempered his mind was by care and sorrow, "like sweet bells jangled, harsh, and out of tune." At other times he thought more soberly of parliament as a diversion. All his life through, however, "most of his convulsions ended in verse." He found occupation in correcting the proof-sheets of *Childe Harold.* He went up to London, not to plunge into a lawless and pitiless course of crime, but to enter upon a political career. He spoke two or three times in the House of Lords on the House-Breaker's Bill, and a petition for Roman Catholic Emancipation, but the publication of *Childe Harold* put an end at once to his parliamentary ambitions. "When *Childe Harold* was published," he says, "nobody thought of my prose afterwards, nor indeed did I."

It has often been asked what was the cause of the instantaneous and wide-spread popularity of *Childe Harold,*

which Byron himself so well expressed in the saying, "I awoke one morning and found myself famous." Chief among the secondary causes was the warm sympathy between the poet and his readers, the direct interest of his theme for the time. In the spring of 1812 England was in the very crisis of a struggle for existence. It was just before Napoleon set out for Moscow. An English army was standing on the defensive in Portugal, with difficulty holding its own; the nation was trembling for its safety. The dreaded Bonaparte's next movement was uncertain; it was feared that it might be against our own shores. Rumour was busy with alarms. All through the country men were arming and drilling for self-defence. The heart of England was beating high with patriotic resolution.

What were our poets doing in the midst of all this? Scott, then at the head of the tuneful brotherhood in popular favour, was celebrating the exploits of William of Deloraine and Marmion. Coleridge's *Christabel* was lying in manuscript. His poetic power was, as he said himself, "in a state of suspended animation." Southey was floundering in the dim sea of Hindu mythology. Rogers was content with his *Pleasures of Memory*. Wordsworth took a certain meditative interest in public affairs, but his poems, "dedicated to liberty," though fine as compositions, have not the fire and sinew, the ardent directness of popular verse. In the earlier stages of the war Campbell had electrified the country with his heart-stirring songs; but by 1812 he had retired from the post of Tyrtæus to become the poet of *Gertrude of Wyoming*. Moore confined himself to political squibs and wanton little lays for the boudoir. It was no wonder that, when at last a poet did appear whose impulses were not merely literary, who felt in what century he was living, whose artistic creations were throbbing with the life of his own age, a crowd at once gathered to hear the new singer. There was not a parish of Great Britain in which there was not some household that had a direct personal interest in the scene of the pilgrim's travels—"some friend, some brother there." The effect was not confined to England; Byron at once had all Europe as his audience, because he spoke to them on a theme in which they were all deeply concerned. He spoke to them, too, in language which was not merely a naked expression of their most intense feelings; the spell by which he held them was all the stronger that he lifted them with the irresistible power of his song above the passing anxieties of the moment. Loose and rambling as *Childe Harold* is, it yet had for the time an unconscious art; it entered the absorbing tumult of a hot and feverish struggle, and opened a way in the dark clouds gathering over the combatants through which they could see the blue vault and the shining stars. If the young poet had only thrown himself forward to ridicule the vanity of their struggles, he would most certainly have been spurned aside in the heat of the fight with anger and contempt; but he was far from being a heartless cynic; his sympathy with the Spanish peasant, his worship of the scenic wonders of the country, his admiration of the heroism of the women, his ardent battle-cry of freedom, burst through his thin pretence of cynicism. The pulse of heroism—heroism conscious of the worst that could happen, and undismayed by the prospect—beat beneath the garb of the cynic. It may have been by unconscious art, but it was not without dramatic propriety, that Byron turned in his second canto from the battlefields of Spain and the tremendous figure of war—

> "With blood-red tresses deepening in the sun,
> And death-shot glowing in his fiery hands—"

to "August Athena," "ancient of days," and the "vanished hero's lofty mound." In that terrible time of change, when every state in Europe was shaken to its foundation, there was a profound meaning in placing before men's eyes the departed greatness of Greece; it rounded off the troubled scene with dramatic propriety. Even the mournful scepticism of *Childe Harold* was not resented at a time when it lay at the root of every heart to ask, Is there a God in heaven to see such desolation, and withhold His hand?

The attention of the public once caught by his sympathy with them, it was rivetted by the theatrical fascination of the character of the pilgrim, whom they persisted in identifying with himself. Young, a man of genius, a lord, and unhappy—unhappy with a sorrow that could not be repressed,—here was a mystery over which speculation could never tire. On Byron himself the first effect of his fame was almost to endanger his poetic gift. He became acquainted with Moore, and went into the fashionable world as a "lion." He had never been in "society" before, and he took to gay life with all the impressionable facility of his character. He was even caught one evening by Mr Dallas in full court dress, and though he repented and did not go, this contemplated breach of his democratic principles, in gratitude for some kind words from the regent, shows how ductile his character was, and how easily he might have been lost to serious poetry if circumstances had not in his youth excluded him from the society of his rank. His docility under new influences was shown in the frank way in which he retracted hard saying after hard saying of his *English Bards*, and in the fact that though he was sufficiently scornful of the gay world to write the *Waltz* (1813), he strenuously denied the authorship. Yet he soon began to tire of fashionable gaieties and to long for solitude.

Byron's poetic power did not advance in strength during the four years of his connection with high life. As he had been led to employ the Spenserian stanza by Campbell's *Gertrude of Wyoming*, which reached his hands just as he was setting out on his travels, he began now to try the metres in which Scott had made his fame. He produced in rapid succession the *Giaour* (May 1813), the *Bride of Abydos* (December 1813), *Corsair* (January 1814), *Lara* (August 1814), *Siege of Corinth* (January 1816), *Parisina* (February 1816). The best of these is the first; but they were received with an enthusiasm which rose higher and higher with each successive publication. It is quite clear that it was against his intention that he had been identified with Childe Harold, but it is equally clear that though the self-restrained, stern, dark-browed heroes are personifications of only one side of his character, one series of moods, and are as unlike as possible to the complete Byron, he was not unwilling that they should be accepted as types of himself. There was another reason for this than a morbid desire to represent himself as worse than he really was. All Byron's friends from his boyhood upwards declare him to have been of a very shy disposition. Never having been in the fashionable world before the spring of 1812, he was far from being at his ease in it; and he masked his shyness under a haughty and reserved manner. How severe a restraint this was on his natural manner may be inferred from the delight with which he escaped from it in the society of his boon companions. It galled his vanity to be thus constrained by people for whom he had no great respect, and it is impossible to help conjecturing that he courted identification with his silent heroes, with their "vital scorn of all," and "chilling mystery of mien," in order to supply a romantic explanation of a reserve which was really due to unconquerable shyness. The influence of personal vanity on Lord Byron's actions, counterbalanced as it was and concealed by an equal warmth of generous feeling, is all but incredible. It was part of that amazing

sensitiveness to the impressions of the present which was the secret of much of the weakness of his character and much of the power of his poetry.

In November 1813 Byron proposed for the hand of Miss Milbanke, only daughter of Sir Ralph Milbanke, a wealthy baronet, and granddaughter and heiress of Lord Wentworth, "an eligible party," he owned in a letter to Moore, though he "did not address her with these views." His suit was rejected, but she expressed a desire to correspond with him. In September 1814 he made another proposal, which was accepted, and the marriage took place on January 2, 1815. On 10th December a daughter, named Augusta Ida, was born. On 15th January 1816 Lady Byron left her husband's house in London on a visit to her father at Kirkby Mallory. On the way she wrote an affectionate letter to Byron, beginning "Dear Duck," and signed "Your Pippin." A few days after he heard from her father that she had resolved never to return to him, and this intelligence was soon confirmed by a letter from herself. In the course of next month a formal deed of separation was drawn up and signed. This is Moore's account of the affair. Lady Byron's account, published on the appearance of Moore's *Life*, differs chiefly as regards the part taken by her parents in bringing about the separation. Byron suspected her mother's influence. Lady Byron took the whole responsibility on herself. Before she left town she thought Byron mad, and consulted Dr Baillie. Dr Baillie persuaded her that this was an illusion. She then told her parents that she desired a separation. The grounds on which she desired this were submitted by her mother to Dr Lushington, who wrote that they justified a separation; but advised a reconciliation. Then Lady Byron had an interview with Dr Lushington, and communicated certain facts, after which he declared a reconciliation impossible. A celebrated living authoress, who was slightly acquainted with Lady Byron, has, it is well known, made a definite statement on this subject, implicating a member of Lord Byron's own family. It is enough, however, to say that there is no evidence in support of the statement, and that it is virtually contradicted by Lady Byron's own behaviour, as she remained on intimate terms with the relative referred to after the separation from her husband.

The real causes of the separation between Byron and his wife must always remain more or less matter of debate, no absolute proof being possible, and disputants reasoning on the presumptions according to temperament and prepossession. Byron's own statement that "the causes were too simple ever to be found out," probably comes nearest the truth. That their tempers were incompatible, that without treating her with deliberate cruelty he tried her forbearance in many ways, and behaved as no husband ought to do, that for her own happiness she had every reason to demand a separation, will readily be believed. After his marriage a huge accumulation of debtors began to press their claims; no less than nine executions were put in force in his house during the year; and Byron, under the indignities to which he had daily to submit, acted with an insane violence which might have justified any woman in believing that she was not safe under the same roof with him. It would have required a very peculiar temper to be compatible with his under the circumstances. A placid, good-tempered woman, with strong good sense, and a boundless affection, which could forget and forgive his most unreasonable outbreaks, might have lived with him happily enough, finding in his sunny moods of playfulness and endearment ample compensation for his fits of gloominess and violence. But Lady Byron was very far from being a woman of that mould. A wife who could coldly ask Byron "when he meant to give up his bad habit of making verses," possessed a terrible power of annoying such a man; her perfect self-command and imperturbable outward serenity, her power of never forgetting an injury and taking revenge with angelic sweetness and apparent innocence of vindictive intention, must have been maddening. The serene way in which she clung to and promoted the maid, Mrs Clermont, in the face of Byron's intolerable dislike to the woman, was gall and wormwood to him. An even-tempered man might have lived with such a person comfortably on terms of mutual politeness; but for a haughty-tempered, violent, fitful, moody man it would have been impossible to find a more incompatible partner.

Why, at the time of the separation, did not the public look upon Byron and his wife as simply an ill-assorted pair who could not agree, and were better to separate? From the first it was rumoured that Lady Byron refused to tell the cause of their separation, whence the public naturally inferred that it must be too terrible to be revealed, and busied themselves inventing and circulating crimes of suitable magnitude. Retribution fell upon Byron for his identifying himself with crime-stained buccaneers. The publication, by an indiscreet friend, of his *Farewell to Lady Byron*, and the verses entitled *A Sketch*, let loose the flood-gates of popular indignation in the press. On the *Farewell* indeed, there was some difference of opinion. A lady correspondent of the *Courier* declared that "if her husband had bidden her such a farewell she could not have helped running into his arms and being reconciled immediately." If Lady Byron had been such a woman—we have no right to blame her because she was not—the separation, in all probability, would never have taken place. The vast majority in English society resented the publication of the *Farewell* as an unworthy attempt to put his wife in the wrong, by holding up her unforgiving temper for public reprobation. We now know that the *Farewell* was written in all sincerity and bitterness of heart, with the tears falling on the paper as he wrote, and that it was published by the indiscreet zeal of a friend to whom he had sent the verses. The fierce attack upon Mrs Clermont in the *Sketch* was universally condemned as unmanly. The two poems are chiefly interesting now as showing the poet's ungovernable incontinence, his passionate craving for sympathy, and the utter distemper of his mind in the bewilderment of misfortune.

Byron took final leave of England in April 1816. From that date the external events of his life, down to his memorable interference in the cause of Greek independence present comparatively little variety, and excite comparatively little interest. Nothing occurred after this to give a new turn or a new colour to his poetic career; the powerful influences which had conspired to torture music out of him were modified by the lapse of time, but very little, if at all, by the incidents of his life. The bitter feelings with which he left England, the angry sense of injustice and spirit of proud and revengeful defiance, alternating hysterically with humble self-reproach and generous forgiveness, passed into lighter forms, but they never ceased to rankle. Like Manfred, he asked in vain for oblivion.

In the thick of his troubles, before leaving England, Byron conceived that he had never been "in a situation so completely uprooting of present pleasure, or rational life for the future." But his going abroad was really a most fortunate step both for his happiness and for the exercise of his genius. Abroad he consented to the sale of Newstead, and his income enabled him to live without being subject to the constant indignities which were such a torture to him at home. There also he found the solitude which he had always desired. "Society," he wrote in a letter to Moore, "as now constituted, is *fatal* to all great original undertakings of every kind," and in his case certainly this was true. His first place of residence abroad was Diodati,

a villa in the neighbourhood of Geneva. He spent the summer there, making two excursions to Switzerland,—one with Hobhouse, a shorter one with Shelley, who also was living at Geneva at the time. His travels through Flanders past the field of Waterloo appear in the third canto of *Childe Harold* (May to July 1816); the idea of writing *Manfred* on his way to Geneva (begun September 1816, finished February 1817) occurred to him on the Jungfrau, where the scene is laid. In November 1816 he removed to Venice, and lived there, with the exception of short visits to Ferrara and Rome, till December 1819, writing fourth canto of *Childe Harold* (June 1817), *Beppo* (October 1817), *Ode to Venice* (July 1818), first canto of *Don Juan* (September 1818), *Mazeppa* (October 1818), second canto of *Don Juan* (December 1818), third and fourth cantos (finished November 1819). The bare catalogue of his literary work shows that the reports of the debauchery in which he lived at Venice, and from which he is said to have been rescued by the Countess Guiccioli, must be taken with a qualification. His acquaintance with this lady began in April 1819, and a mutual attachment sprang up at once. In December 1819 he removed to Ravenna. In the following month the Countess Guiccioli, having separated from her husband, occupied, under her father Count Gamba's presence and sanction, a suite of rooms in the same house with Byron at Ravenna; and though the families were formally separate, the union was not broken till Byron's departure for Greece. When, two years later, in 1821, the Gambas, in consequence of their connection with revolutionary movements, were ordered to quit Ravenna, Byron removed to Pisa and lived with them under the same roof as before. Leigh Hunt, who also was received into Byron's house with his wife and children, has given us a somewhat ill-natured but sufficiently faithful picture of his life here, which was simply that of a busy domesticated literary man, with a taste for riding, swimming, and marksmanship. During Byron's residence here Shelley was drowned in the Gulf of Spezzia. In September 1822, the Gambas were ordered by the Tuscan Government to quit Pisa, and Byron removed with them to Genoa. His life at Genoa has been described with traces of airy malice, but with much vivacity and abundance of detail, by Lady Blessington.

While he lived with the Countess Guiccioli Byron's literary industry was prodigious. The following is the list:—Translation of the first canto of *Morgante Maggiore*, February 1820; the *Prophecy of Dante*, March 1820; translation of *Francesca de Rimini*, March 1820; *Marino Faliero*, April to July, 1820; fifth canto of *Don Juan*, October to November 1820; *The Blues*, November 1820; *Sardanapalus*, January to May 1821; *Letters on Bowles*, February and March 1821; *The Two Foscari*, June to July 1821; *Cain*, July to September 1821; *Vision of Judgment*, September 1821; *Heaven and Earth*, October 1821; *Werner*, November 1821 to January 1822; *Deformed Transformed*, begun November 1821, finished August 1822; *Don Juan*, sixth, seventh, and eighth cantos, February 1822; ninth, tenth, and eleventh cantos, August 1822; *The Age of Bronze*, January 1823; *The Island*, February 1823; *Don Juan*, twelfth and thirteenth cantos, February 1823.

This quiet industrious life, however, did not cure him of his constitutional melancholy and restlessness. The curse of his nature was that he exhausted his pleasures too quickly. He too soon became dissatisfied with past triumphs. Much as he enjoyed the success of the works which poured with such rapidity from his pen, he began to harp on what he might have done; began to think that the tide was turning against him in England, and to hunger for new distinction. In this spirit, towards the end of 1821 he commenced those negotiations for the publication of a journal in England in conjunction with Shelley and Leigh Hunt, which ended in the abortive *Liberal*. The *Vision of Judgment*, the greatest of modern satires, appeared in the first number of the *Liberal*, in the summer of 1822; only three more numbers were published. According to Moore, the sign of an intention to take an active part in alliance with English Radicalism did more to make Byron unpopular in England than the most shocking of his poems. It was fortunate for his popularity that a more glorious enterprise offered itself to him in the Greek struggle for independence. He was brought into connection with this through the London Greek committee, of which he was appointed a member in May 1823. He at once decided to take action, raised 50,000 crowns, bought an English brig of 120 tons, and sailed from Genoa with arms and ammunition in July. The high hopes with which he set out were soon broken down; the Greeks had no plans, and he was compelled to spend five months of inglorious delay at Cephalonia. Reaching Missolonghi in December, after a chase by Turkish cruisers, he found dissension among the Greek chiefs and insubordination among their followers. He was appointed commander-in-chief of an expedition against Lepanto; but before anything could be done he was seized with fever, and died on the 19th April 1824.

It is yet, perhaps, too soon to hazard a speculation as to the permanence of Byron's fame. That he holds a lower place in the opinion of the present generation than of his own, so far at least as concerns his own country, is undeniable, and is probably due to the fact that poets now are tried by more strictly artistic standards; verses are judged, proportions measured, rare and precious excellences appreciated with the jealous scrutiny and skilled recognition of professional workmen. Tried by such standards, Coleridge, Keats, and Shelley must be pronounced Byron's superiors. The greatest modern authority on verse, Mr Swinburne, comments justly on Byron's imperfect mastery of his materials:—"One native and incurable defect grew up and strengthened side by side with his noblest qualities—a feeble and faulty sense of metre. No poet of equal or inferior rank ever had so bad an ear. His smoother cadences are often vulgar and facile; his fresher notes are often incomplete and inharmonious. His verse stumbles and jingles, stammers and halts, where is most need for a swift and even pace of musical sound. The rough sonorous changes of the songs in *The Deformed Transformed* rise far higher in harmony, and strike far deeper into the memory than the lax, easy lines in which he at first indulged; but they slip too readily into notes as rude and weak as the rhymeless, tuneless verse in which they are so loosely set, as in a cheap and casual frame. The magnificent lyric measures of *Heaven and Earth* are defaced by the coarse obtrusion of short lines with jagged edges—no small offence in a writer of verse." In point of metre, too, Byron showed none of the originality which we should expect in a poet who delighted in his materials for their own sake. The god of his idolatry was Pope, towards whom his sympathies were drawn chiefly by the elder poet's modern and practical point of view, and quick interest in passing affairs, and he began by imitating with very indifferent success Pope's satiric couplet. But his successes were achieved in more popular measures. He was the least possible of an antiquarian poet, whether in matter or in form. His way was to take up any measure that struck him as effective, and try his hand on it. Campbell's example suggested the Spenserian stanza; Scott and Coleridge the rapid octosyllables of his *Eastern Tales*; and he would never have thought of the *ottava rima* of *Beppo* and *Don Juan* but for Frere's *Whistlecraft*. *Whistlecraft* appeared in 1817, and the moment it fell into his hands Byron

recognized the value of the instrument, and lost no time in making it his own.

It was not on the artistic side that Byron's strength lay. Words were far from niggardly in their supplies to him: they flowed in upon him with sufficient readiness for free and direct expression; his thoughts were not blunted, his conceptions were not turned awry by hopeless struggling with stubborn material, but language was not pliant in his hands for the finer achievements of art. The truth is, he felt too deeply to be a poet of the very highest rank; the feeling of the moment took too large and embarrassing a hold of him to leave his hand free for triumphs of execution. This interfered both with the perfecting of details, and with the severe ordering of parts into an artistic whole. In Byron we are always struck more with the matter than with the form. It is his theme that absorbs attention, and the impetuous vehemence and stormy play of passion with which he hurries it on. This is, doubtless, an insecure foundation for lasting fame. The work of a man so keenly alive to the impressions of the hour, so closely bound up with his generation as Byron, runs a risk of perishing when the things that most deeply stir that generation have ceased to stir mankind. The secret of his tremendous power was his passionate sympathy with his own time. By the accidents of birth and circumstances, he was placed in opposition to the existing order of things, and his daring temper made him the exponent of the spirit of revolution. He is the greatest modern preacher of "liberty, equality, and fraternity." His little aristocratic assumptions were as superficial as his professions of antiquarian poetic loyalty. Nothing irritated him more than to deny him any of the privileges of his rank, but he never used the advantage of his social superiority in any of the contests in which he was involved, and in his loves and his friendships he showed regard only for the individual. He was a warm champion of the established fame of Pope against innovators, but he practised the innovations himself with such effect that he has been called—a foolish enough phrase, certainly, but intelligible—"the interpreter of Wordsworth to the multitude." Abroad, Byron's influence was, from the appearance of *Childe Harold*, no less conspicuous than at home. It has even been said that he was the first Englishman who made English literature known throughout Europe. Even such men as Lamartine, who deplored Byron as an incarnation of Satan, acknowledged his power; Lamartine says that Byron was "a second Ossian to him," and tells us that he was afraid to read him in his youth lest he should be perverted to his beliefs. Heine invited the compliment of being called "the German Byron." He is believed to have largely influenced the revolutionary movement in Germany, and he gave a direct stimulus to the liberators of Italy. Byron is the favourite poet of our English speaking fellow-subjects in India; the educated Bengalee knows him by heart. On the Continent his influence has rather increased than diminished. Only the other year a glowing eulogy of his genius was written by Castelar, the literary leader of republicanism in Spain. At home of late we have been accused of neglecting Byron, and the fact is significant. Such stormful and melancholy poetry as his must always be at the height of its popularity in times of conflict. The disturbed state of the Continent is more favourable to its spirit than the piping times of peace which have prevailed for a generation in England. Men who are content with the old things, and men who renounce old things with a light heart, can have little affinity with his deep-rooted sadness, his pride of defiant struggle, his flashes of defiant merriment; all this seems hysterical, affected, and unreal,—and unreal it no doubt is, in the sense that the feelings of men under the tension of conflict must appear full of false notes to men who look on out of a normal condition of settled tranquillity.

The most hopeful circumstance for the permanence of Byron's name is that he stands at the opening of a new era as its largest literary figure. Sooner or later, as new phases of thought and sentiment supervene upon the old, his writings must pass out of the catalogue of popular literature, but his personality will always fascinate. He is like Hamlet in this respect. It may safely be predicted that Byron will not cease to be read till Hamlet has ceased to be studied. There is not a little in common between the characters, in spite of superficial difference. In the desolation of his youth, in his moodiness, in his distempered mobility between the extremes of laughter and tears, in his yearning for sympathy, his intensity of friendship, his dark fits of misanthropy, his habit of brooding over the mysteries of life, Byron unconsciously played the character of Hamlet with the world for his stage, and left a kindred problem for the wonder of mankind,—a problem which no analysis can make clear, and which every one may pray that it be not given them to understand.

It has often been said that Byron could draw but one character, and that his own This is not more than a half truth. It is true that Byron's genius was more lyrical than dramatic. "Many people," he said himself, "think my talent *essentially undramatic*, and I am not clear that they are not in the right." But he also said that while he, "like all imaginative men, embodied himself with the character while he drew it," he did so "not a moment after the pen was from off the paper." The difference between saying that Byron loved to picture himself in various circumstances, and that he could not set himself to the artistic portraiture of any character in which he was not interested, may not be great, but it is the difference between a true view and a false view of his artistic method. He was undramatic in this sense, that his imagination did not enter freely and self-delightedly into various forms of life. When Moore thought he had found a beautiful subject for Byron's genius, and wrote the details to him, Byron could not enter into the situation. His *Monody on Sheridan* is weak, because it was not spontaneous. But when he found a situation or a character which naturally attracted him, and which he was able to understand, his method was not, as is implied by the language in which his want of dramatic faculty is often expressed, to bring the situation or the character nearer to his own experience, but he tried to identify himself with the life of his subject, and laboured at details with almost pre-Raphaelitic minuteness. We do right to call him undramatic still, because a dramatic genius is doing constantly and by the law of his nature what Byron could only do rarely and with a limited range. But it is wrong to say that he was always drawing himself. There are considerable intervals between Sardanapalus, Marino Faliero, Alp, Lara, and Manfred, although in those and in all his leading characters we are more struck with what they have in common with their author, the affinity that led him to deal with their fortunes, than we are with their separate individualities. The Countess Guiccioli has given in the case of Marino Faliero a good example of the way in which he prepared himself for his work. He was struck with the tradition of Faliero's conspiracy in his old age against the state which he had served so well in youth and middle age, immediately after his arrival in Venice, but at first he was unable to satisfy himself as to the motive. The ordinary histories, which he searched through with care, ascribed it to an old man's jealousy of a young wife, but this Byron's instinct rejected. He passed hours in the hall of the great council, stared at the record of Faliero's decapitation, lingered about the tomb, and called up and realized every recorded circumstance of his life, keenly

studied the characters of living Venice. It was not till four years afterwards that he satisfied himself as to the motive, and the discovery of an old document afterwards proved that his reading of history was correct. In other cases he showed the same studious care for accuracy, the very opposite of rash and dashing identification of characters with himself. In most of his tales and dramas there is an historical basis, and the basis is scrupulously ascertained. He particularly prided himself upon the truth of his local colouring.

The most interesting and complete portrait of Byron is perhaps that drawn by Lady Blessington, who saw him at Genoa a few months before his departure for Greece. It is not so favourable as some, but it is peculiarly valuable because taken from a definite point of view, that of a clever woman of the world and practised critic of appearance and manner. "I had fancied him," she says, "taller, with a more dignified and commanding air, and I looked in vain for the hero-looking sort of person with whom I had so long identified him in imagination. His appearance is, however, highly prepossessing, his head is finely shaped, and the forehead open, high, and noble, his eyes are grey and full of expression, but one is visibly larger than the other, his mouth is the most remarkable feature in his face, the upper lip of Grecian shortness, and the corners descending, the lips full and finely-cut. In speaking he shows his teeth very much, and they are white and even, but I observed that even in his smile—and he smiles frequently—there is something of a scornful expression in his mouth that is evidently natural, and not, as many suppose, affected. . . . His countenance is full of expression, and changes with the subject of conversation; it gains on the beholder the more it is seen, and leaves an agreeable impression. . . . He is very slightly lame, and the deformity of his foot is so little remarkable that I am not now aware which foot it is. His voice and accent are peculiarly agreeable, but effeminate—clear, harmonious, and so distinct that, though his general tone in speaking is rather low than high, not a word is lost. . . . . I had expected to find him a dignified, cold, reserved, and haughty person, resembling those mysterious personages he so loves to paint in his works, and with whom he has been so often identified by the good-natured world, but nothing can be more different; for were I to point out the prominent defect of Lord Byron, I should say it was flippancy, and a total want of that natural self-possession and dignity which ought to characterize a man of birth and education." Such, judged by the social standard of his own country, was the look and personal manner of the greatest literary power of this century.

The best edition of Byron's works is that published by Murray, with illustrative extracts from his letters and diaries, and from the criticisms of his contemporaries. A selection from his works, edited and prefaced by Mr A. C. Swinburne, is published by Moxon. The facts of his life may be studied in Moore's *Life, Letters, and Journal of Lord Byron*, supplemented by Leigh Hunt's *Lord Byron and his Contemporaries*, Lady Blessington's *Conversations with Lord Byron*, Trelawney's *Recollections of Shelley and Byron*, and the Countess Guiccioli's *Lord Byron jugé par les témoins de sa vie* (translated under the title of *Recollections of Lord Byron*). Numerous allusions to Byron occur in the published memoirs of his contemporaries, such as the *Shelley Memorials* and Crabb Robinson's *Diary*. Karl Elze's biography (translated), although often mistaken in its conception of his character, is valuable as a collection of facts. (W. M.)

BYRON, Hon. John (1723–1786), admiral and circumnavigator, second son of the fourth Lord Byron, and grandfather of the poet, was born November 8, 1723. While still very young accompanied Anson in his voyage of discovery round the world. During many successive years he saw a great deal of hard service, and so constantly had he to contend, on his various expeditions, with adverse gales and dangerous storms, that he was aptly nicknamed by the sailors, "Foul-weather Jack." It is to this that Lord Byron alludes in his famous *Epistle to Augusta*:—

> "A strange doom is thy father's son's, and past
> Recalling as it lies beyond redress,
> Reversed for him our grandsire's fate of yore,
> He had no rest at sea, nor I on shore.

In 1769 he was appointed governor of Newfoundland. In 1775 he attained his flag rank, and in the following year became a vice-admiral. In 1778 he was despatched with a fleet to watch the movements of the Count d'Estaing, and in July 1779 fought an indecisive engagement with him off Grenada. He soon after returned to England, retiring into private life, and died April 10, 1786.

BYSTRÖM, Johann Nicolaus (1783–1848), Swedish sculptor, was born December 18, 1783, at Philipstad. At the age of twenty he proceeded to Stockholm and studied for three years under Sergell. In 1809 he gained the academy prize, and in the following year visited Rome. He sent home a beautiful work, The Reclining Bacchante, in half life size, which raised him at once to the first rank among Swedish sculptors. Oh his return to Stockholm in 1816 he presented the crown prince with a colossal statue of himself, and was entrusted with several important works. Although he was appointed professor of sculpture at the academy, he soon returned to Italy, and with the exception of the years from 1838 to 1844 continued to reside there. He died at Rome in 1848. Among Byström's numerous productions the best are his representations of the female form, such as Hebe, Pandora, Juno suckling Hercules, and the Girl entering the Bath. His colossal statues of the Swedish kings are also much admired.

BYZANTINE EMPIRE. See Greek Empire.

BYZANTINE HISTORIANS. The historians who have related the transactions under the Eastern, Greek, or Byzantine empire, for the millennium intervening between the death of Theodosius and the Turkish conquest of Constantinople, are collectively classed together under the above designation. Until, however, the middle of the 6th century, they are, with one conspicuous exception, too merely fragmentary to deserve special notice. This exception is Procopius, the Polybius of his age, whose histories are of such importance as to demand a separate article. We shall arrange his successors in chronological order, distinguishing between the historians properly so called and the chronologers.

Historians.—I. Agathias of Myrina in *Ætolia*, was born under Justinian, about 536 A.D., and is believed to have died under Tiberius the Second, about 580. His character as an epigrammatist and an editor of poetry has been already considered under the head Anthology. We are indebted to him in his historical capacity for an extremely valuable narrative of six of the most eventful years of the Greek empire, 553–558. The first book details the conquest of Italy from the Goths by Justinian's general Narses; the remainder describe, along with other incidents, the Persian war of 554–556, the two great earthquakes of 554 and 557, the great plague, the rebuilding of St Sophia, and Belisarius's last exploits against the Bulgarians. The history terminates abruptly, and was probably left unfinished. As a narrator, Agathias is sensible and impartial, but deficient in general knowledge, and far below the standard of a philosophic historian. His style is rhetorical, but not unpleasing. II. Menander Protector, the far inferior imitator of Agathias, lived under Mauricius, whose reign began in 581, and continued the history of Agathias to the date of the accession of that emperor. His work was comprised in eight books, which are entirely lost, with the exception of numerous extracts relating to embassies preserved in the collection Περὶ πρεσβειῶν—the 27th and only existing book of the extensive compilation of historical excerpts made by the Emperor Constantine Porphyrogenitus.

III. THEOPHYLACTUS of Simocatta, a sophist and civilian of Egyptian extraction, wrote the history of the Emperor Mauricius (582–602) in eight books, all of which are preserved. The work seems to have been completed under Heraclius. Theophylactus lived until 628 or 629. He is an accurate and not inelegant writer, but frequently trivial and frigid. IV. JOANNES of Epiphaneia, a contemporary of Theophylactus, wrote the history of the wars of the Greeks and Persians from the latter part of Justinian's reign until the restoration of Chosroes II. by Mauricius (591). His history has never been printed, but is said to exist in MS. at Heidelberg. V. The Emperor CONSTANTINE PORPHYROGENITUS (reigned 911–959). Among the many services rendered to literature by this learned sovereign is to be enumerated his history of his grandfather Basil the Macedonian, emperor from 867 to 886. VI. GENESIUS, who lived in the time of Constantine Porphyrogenitus, wrote by his order the history of Basil II. and of his four immediate predecessors (813–886). The work is brief and meagre, but is almost the only authority we possess for a portion of the period described. VII. JOANNES CAMENIATA, a native of Thessalonica, and cross-bearer to the archbishop, wrote an account, which has been preserved, of the sack of that wealthy city by the Saracens in 904. Cameniata himself was one of the captives, and his narrative is very lively and valuable. VIII. LEO DIACONUS, an ecclesiastic in the latter half of the 10th century, is the author of an indifferently written, but honest and instructive, narrative of the remarkable period of national recovery under the emperors Romanus II., Nicephorus Phocas, and John Zimisces, when Crete was reconquered, Syria invaded, and the Russians driven out of Bulgaria (959–975). Leo wrote at least as late as 993. IX. NICEPHORUS BRYENNIUS, the son-in-law of the Emperor Alexius Comnenus, and one of the first statesmen and generals of his time, wrote in four books the history of the empire under the Comneni from 1057 to 1081. X. His still more celebrated wife, ANNA COMNENA, daughter of the Emperor Alexius, and the marvel of her sex at that extremely low period of female education, wrote (1148) the history of her father in fifteen books. The period of Alexius is peculiarly interesting as that in which the barrier of Byzantine isolation was broken down, and the East and West brought into contact by the encroachments of the Normans on the Eastern empire and by the Crusades. We cannot be too grateful to the Princess Anna for her vivid sketch of the arrival of the Crusaders at Constantinople, and the relations between them and the Byzantine court. Her work, however, must be used with great caution. Gibbon's employment of it is an example of his usual discernment. XI. Her history was continued by JOANNES CINNAMUS, one of the most eminent of all the Byzantine historians. He was one of the imperial notaries under the reign of Manuel Comnenus (1143–1180), an office nearly corresponding to that of a modern secretary of state. He had, consequently, great administrative experience, and a thorough knowledge of the relations of the empire with foreign states, and of the internal affairs of the latter. He is thus in an excellent position for writing history, besides which his own judgment and sagacity are of a very superior order, and his style is commonly terse and clear. Like most writers who have themselves participated in the transactions they describe, he is not altogether exempt from partiality. His history comprehends the period from the death of Alexius Comnenus in 1118 to the siege of Iconium by Manuel Comnenus in 1176, four years before the death of that emperor. There is little doubt that Cinnamus brought his work down to the close of Manuel's reign, and that the conclusion is lost. XII. NICETAS ACOMINATUS, or CHONIATES, a patrician and holder of many important public offices under the emperor Isaac Angelus at the beginning of the 13th century, described the same period as Cinnamus, but continued his narrative to 1206. The latter books of Nicetas's history possess especial importance, inasmuch as they contain the Byzantine account of the taking of Constantinople by the Latins in the fourth crusade (1204). Nicetas's own palace was burned and plundered, and he escaped with difficulty to Nicæa, where he composed his history under the protection of the emperor Theodore Lascaris. His narrative, though too rhetorical, is striking and pathetic; it necessarily requires careful comparison with the Latin accounts. The remainder of his history is also valuable. He is also said to be the author of an account of the statues destroyed by the Latins, which, however, is thought to have been interpolated by a later writer. It has been published by Wilken (Leipsic, 1830). XIII. GEORGIUS ACROPOLITA, an eminent scholar and diplomatist, who lived from 1220–1282, wrote the history of the Eastern empire during its subjugation by the Latins (1204–1261). The work is so brief that it has been regarded as merely an epitome of Acropolita's original history. XIV. GEORGIUS PACHYMERES, a priest and ecclesiastical jurist under Michael and Andronicus Palæologus, wrote the history of these emperors (1258–1308) in thirteen books. Pachymeres is one of the best of the Byzantine historians; his style is singularly good for his age, and his tone dignified and impartial. XV. NICEPHORUS GREGORAS, a man of great learning, but passionate and untrustworthy as an historian, wrote the history of his country from 1204–1358, in thirty-eight books, the last fourteen of which remained unpublished until 1855, when they were edited at Bonn by Immanuel Bekker. After the recovery of Constantinople by the Greeks in 1261, Byzantine politics entered into a new phase; the feeble and distracted empire, unable to make head against the Turks, was compelled to lean for support upon the European powers, which it sought to obtain by patching up the long-standing religious schism. Greeks and Latins, however, were equally resolved to concede nothing save in appearance, and the history of the time is to a great extent that of hollow negotiations, meant only to deceive. In these Gregoras had a considerable share; he also took an active part in the internal religious controversies of his church, and his personal knowledge of affairs imparts considerable value to his history. He was at one time a favourite of the Emperor Cantacuzenus, but was subsequently persecuted by him. He possessed extensive attainments, and is especially celebrated for having anticipated the astronomers of Pope Gregory XIII. in the correction of the Julian Calendar. XVI. The Emperor JOHN CANTACUZENUS, after his abdication, wrote the history of his times from 1320–1357, including the fifteen years of his own eventful reign. This "is written," as Dr Plate observes, "with elegance and dignity, and shows that the author was a man of superior intelligence, fully able to understand and judge of the great events of history;" but Gibbon's remark is no less just that Cantacuzenus "presents, not a confession, but an apology of the life of an ambitious statesman. Instead of unfolding the true counsels and characters of men, he displays the smooth and specious surface of events, highly varnished with his own praises and those of his friends." The truth is arrived at by a comparison of Cantacuzenus with the rival and inimical narrative of Nicephorus Gregoras, so far as they cover the same ground. XVII. JOANNES CANANUS wrote an account of the siege of Constantinople by Amurath II. in 1422; and XVIII. JOANNES ANAGNOSTES described the capture of Thessalonica by the same Sultan in 1430. XIX. MICHAEL DUCAS, the chief historian of the fall of the Greek empire, escaped from the sack of Constantinople

to Lesbos, where he entered into the service of the prince of that island, and wrote his history after the reduction of Lesbos by the Turks in 1462. It commences in 1342, and goes down to the conquest of Lesbos. Ducas is the most difficult and barbarous of all the Byzantine historians, and the only one who appears entirely unacquainted with classical models. At the same time he is among the most intelligent, impartial, and sagacious. The ruin of the Greek empire has also been recorded by XX. Georgius Phrantzes and XXI. Laonicus Chalcocondyles Both of these were eminent among the statesmen of their disastrous period, and Phrantzes in particular played a very important part in diplomacy. Broken hearted at the capture of his native city and the death of his son and daughter in slavery, he retired to a monastery in Corfu, where he wrote his *Chronicon* about 1477, to which year it extends. It commences at the year 1259, but by far the most valuable portion is that which records the transactions of the author's lifetime, and the value of this is very great. Chalcocondyles, beginning at 1298, brings his history down to the invasion of the Morea by the Turks in 1463. He also is an accomplished man, of much experience in public business; and although his digressions respecting the affairs and manners of other nations are irrelevant, and betray ignorance, they are interesting as an index to the knowledge possessed by his countrymen at his time.

II. Chroniclers and Chronologers.—The chronologers usually published in the Byzantine collection are frequently very valuable, but neither their lives nor their writings need detain us long. They are I. Georgius Syncellus, the attendant (*syncellus*) upon the patriarch Tarasius, about the beginning of the 9th century. His unfinished chronicle extends from Adam to Diocletian, and was continued to 813 A.D. by II. Theophanes Isaurus, a martyr in the cause of image worship. III. Leo Grammaticus and IV. Georgius Monachus continued Theophanes to 948 and 944 respectively. V. The chronicle of the Syrian Joannes Malalas extends from the beginning of the world to the year 566 Malalas is usually supposed to have lived in the 9th century, and to have left his work incomplete, but some regard him as contemporary of Justinian. VI. Nicephorus Patriarcha, Patriarch of Constantinople under Leo the Armenian, early in the 9th century, compiled a chronological history from the murder of the Emperor Mauricius to his own times, and an abridged chronological manual of events from the Creation. VII. Julius Pollux, a writer of the 10th century, compiled a chronology, chiefly of ecclesiastical occurrences, to the year 963, which has only been printed as far as the death of Valens (377). VIII. The contemporary chronicle of Hippolytus of Thebes is of little value. IX. The valuable *Chronicon Paschale*, which extends to 1042, is the work of three anonymous writers. There has been considerable difficulty in settling the respective claims to originality of X. Joannes Scylitza and XI. Georgius Cedrenus, but the latter was probably the copyist. The contrary opinion has prevented the publication of Scylitza's work, with the exception of the portions not transcribed by Cedrenus. These extend from 1057 to 1080. The chronicle of Cedrenus reaches from the Creation to the former of these dates. XII. The chronicle of Constantine Manasses is written in political verses, and extends from the beginning of the world to the accession of Alexius Comnenus in 1281. XIII. Michael Glycas, a writer of uncertain date, published a general chronology down to the year 1118. XIV. The abbreviated chronicle of Joel reaches the capture of Constantinople by the Latins in 1204 XV. The chronicle of Georgius Codinus, a writer of the 15th century, comes down to the capture of Constantinople, and is associated with a compilation respecting the antiquities of the city, which is of much greater value.

The contribution of the Byzantine historians to literature may be compared with the part enacted by the Byzantine empire in the history of the world. That empire added nothing to the treasures of civilization, but it preserved much. Like the earth in winter, it seemed barren and unlovely, but it kept the good seed hidden in its bosom for better days. Had it perished before the intellectual revival of Western Europe, the solution of continuity between ancient and modern culture would have been irreparable. In like manner the Byzantine historians preserved the traditions of historical composition, while their brethren of the West were merely chroniclers and annalists. They have safely embalmed in their generally unattractive pages a vast mass of most valuable information, for which we are in most cases solely dependent upon them, and they aid us to reconstruct the polity, and to some extent the social life, of what was for several centuries the only really civilized Christian state in the world. They are undoubtedly for the most part perfectly ignorant of the significance of their own times; they have postponed what was really interesting to barren details of battles and court intrigues, and have wasted opportunities which would have been invaluable to a philosophic historian. Cinnamus and Ducas are the only two with any claim to this character, and Anna Comnena is the only artist. When, however, all their disadvantages are taken into consideration, it will probably be deemed that they are much better than might have been expected. They were isolated from all the rest of the known world by prejudice, policy, and religious hatred. There was no scientific or other intellectual movement in their times, no aspiration for liberty, no conception of a more liberal culture; they were crushed by a rigid despotism, and enthralled by an abject superstition. Under these circumstances the good sense and sagacity of many among them are very remarkable, and are chiefly to be explained by the large proportion among them of men accustomed to practical life and public affairs. Their roll includes sovereigns, generals, prime ministers, secretaries of state, diplomatists, and other important public officers; even the ecclesiastics among them are not recluses but men versed in business. The Byzantine civil service was the strong point of the empire, and its solid if prosaic qualities are admirably reflected by its literary representatives.

The first collective edition of the Byzantine historians was published at Paris, 1648–1702, in 27 volumes, with a preface by Labbe, and notes and translations by Fabrotus, Combefisius, and others. It was reprinted, with additions, at Venice, 1729–33. These editions are superseded by the great edition of Bonn, 1828–55, in 48 volumes, undertaken at the recommendation and under the superintendence of Niebuhr, and continued after his death under the patronage of the Royal Prussian Academy. The separate volumes are edited by Bekker, Dindorf, Hase, and other distinguished scholars; nevertheless, according to Brunet, "de bons textes des historiens byzantins restent encore à donner." Like former collections it contains several works of value not strictly belonging to Byzantine history, but illustrative of it. No guide to Byzantine history is comparable to Gibbon, whose narrative of this period is an unparalleled literary feat of masterly and impartial condensation. See likewise Lebeau, *Histoire du Bas Empire*, Paris, 1824–36. Mr Finlay's volumes are also invaluable companions to the Byzantine historians. Of special works on the subject, the most important is Hankius, *De Byzantinarum rerum scriptoribus Græcis*, Leipsic, 1677, a book distinguished by extensive and accurate erudition, but necessarily deficient as respects the writers not published in the author's day. It contains notices of Byzantine ecclesiastical writers also. Special points of interest are discussed in Von Hammer's essay in the Göttingen *Annals*, (vol. 6) on the correction of the Byzantine historians from Ottoman sources; in Heyne's *Antiquatates Byzantinæ* (1808–11); and in Hullman's *Geschichte des Byzantinischen Handels* (1808). Sabatier's great work on Byzantine numismatics also affords much illustrative matter, and there is a lively sketch of the general social condition of the Eastern Empire in Augustin Marrast's *Esquisses Byzantines* (Paris, 1874.) (R. G.)

BYZANTIUM, an ancient Greek city on the shores of the Bosphorus, occupied the most easterly of the seven hills on which the modern Constantinople has been built. It is said to have been founded by a band of Megarians, 667 B.C., but the original settlement having been destroyed in the reign of Darius Hystaspes by the Satrap Otanes, it was recolonized by Pausanias, who wrested it from the hands of the Medes after the battle of Platæa (479 B.C.)—a circumstance which has led several ancient chroniclers to ascribe its foundation to him. Its situation, said to have been fixed by the oracle of Apollo, was remarkable for beauty and security. Its position on the Bosphorus gave it complete control over the extensive corn-trade carried on by the merchants of the West with the northern shores of the Euxine; the absence of tides and the depth of its harbour rendered its quays accessible to vessels of large burden; while the tunny and other fisheries at the mouth of the Lycus were so lucrative as to procure for the deeply-curved bay into which that river fell the appellation of the Golden Horn. The greatest hindrance to its continued prosperity consisted in the miscellaneous character of the population, partly Lacedæmonian and partly Athenian, who flocked to it under Pausanias. From this circumstance it was a subject of dispute between these states, and was alternately in the possession of each, till it achieved its independence of both only to fall into the hands of the Macedonians; and from the same cause arose the violent contests of its intestine factions, which ended in the establishment of a rude and turbulent democracy. About seven years after its second colonization, Cimon wrested it from the Lacedæmonians; but in 440 B.C., it revolted and returned to its former allegiance. Alcibiades, after a severe blockade (408 B.C.), gained possession of the city through the treachery of the Athenian party; and it continued an ally of Athens until 405 B.C., when it was retaken by Lysander after the battle of Ægos-potami, and placed under a Spartan harmost. It was under the Lacedæmonian power when the Ten Thousand, exasperated by the conduct of the governor, made themselves masters of the city, and would have pillaged it had they not been repressed by the firmness and promptitude of Xenophon. In 390 B.C. Thrasybulus, with the assistance of Heraclides and Archebius, succeeded in expelling the Lacedæmonian oligarchy, and in restoring democracy and the Athenian influence both in Byzantium and Chalcedon. After having withstood an attempt under Epaminondas to restore it to the Lacedæmonians, Byzantium joined with Rhodes, Chios, Cos, and Mausolus, king of Caria, in throwing off the yoke of Athens, but soon after sought Athenian assistance when Philip of Macedon, having overrun Thrace, advanced against it. The succours which were sent from Athens under Chares, on their arrival suffered a severe defeat from Amyntas, the Macedonian admiral, but in the following year gained a decisive victory under Phocion, and compelled Philip to raise the siege. The deliverance of the besieged from a surprise, by means of a flash of light which revealed the advancing masses of the Macedonian army, has rendered this siege peculiarly memorable. As a memorial of the miraculous interference the Byzantines erected an altar to Torch-bearing Hecate, and stamped a crescent on their coins as a symbol of the portent, a device which is retained by the Turks to this day. They also granted the Athenians extraordinary privileges, and erected a monument in honour of the event in a public part of the city. During the reign of Alexander, Byzantium was compelled to acknowledge the Macedonian supremacy; after the decay of the Macedonian power, it regained its independence, but suffered from the repeated incursions of the Scythians. The losses which they sustained by land roused the Byzantines to indemnify themselves on the vessels which still crowded the harbour, and the merchantmen which cleared the straits; but this had the effect of provoking a war with the neighbouring naval powers. The exchequer being drained by the payment of 10,000 pieces of gold to buy off the Gauls who had invaded their territories about 279 B.C., and by the imposition of an annual tribute which was ultimately raised to 80 talents, they were compelled to exact a toll on all the ships which passed the Bosphorus,—a measure which the Rhodians resented and avenged by a war, wherein the Byzantines were defeated. The retreat of the Gauls enabled Byzantium to render considerable services to Rome in the contests with Philip II., Antiochus, and Mithridates. During the first years of its alliance with Rome it held the rank of a free and confederate city; but having sought the arbitration of the capital on some of its domestic disputes, it was subjected to the imperial jurisdiction, and gradually stripped of its privileges, until reduced to the status of an ordinary Roman colony. In recollection of its former services, the Emperor Claudius remitted the heavy tribute which had been imposed on it; but the last remnant of its independence was taken away by Vespasian, who, in answer to a remonstrance from Apollonius of Tyana, taunted the inhabitants with having "forgotten to be free." During the civil wars, it espoused the party of Pescennius Niger; and though skilfully defended by the engineer Periscus, it was besieged and taken (196 A.D.) by Severus, who destroyed the city, demolished the famous wall, which was built of massive stones so closely rivetted together as to appear one block, put the principal inhabitants to the sword, and subjected the remainder to the Perinthians. This overthrow of Byzantium was a great loss to the empire, since it might have served as an effective protection against the Goths, who afterwards sailed past it into the Mediterranean. Severus, however, afterwards relented, and, rebuilding a large portion of the town, gave it the name of Augusta Antonina. He ornamented the city with baths, and surrounded the hippodrome with porticoes; but it was not till the time of Caracalla that it was restored to its former political privileges. It had scarcely begun to recover its former flourishing position when, from the capricious resentment of Gallienus, the inhabitants were once more put to the sword, and the town given up to be pillaged. From this disaster the inhabitants recovered so far as to be able to give an effectual check to an invasion of the Goths in the reign of Claudius II., and its fortifications were greatly strengthened during the civil wars which followed the abdication of Diocletian. Licinius, after his defeat before Adrianople, retired to Byzantium, where he was besieged by Constantine, and compelled to surrender. To check the inroads of the barbarians on the north of the Black Sea, Diocletian had resolved to transfer his capital to Nicomedia; but Constantine, struck with the advantages which the situation of Byzantium presented, resolved to build a new city there on the site of the old, and transfer the seat of government to it. The design was quickly put into execution, and the new capital was inaugurated with special ceremonies 330 A.D. See CONSTANTINOPLE.

The ancient historians invariably note the profligacy of the inhabitants of Byzantium. They are described as an idle and depraved people, spending their time for the most part in loitering about the harbour, or carousing over the fine wine of Maronea. In war they trembled at the sound of a trumpet, in peace they quaked before the shouting of their own demagogues; and during the assault of Philip II. they could only be prevailed on to man the walls by the savour of extempore cook-shops distributed along the ramparts. The modern Greeks attribute the introduction of Christianity into Byzantium to St Andrew; and it certainly had some hold there in the time of Severus.

C

C is the third letter of the English alphabet, and of the other alphabets derived from the Latin. Its history has been singular. It was the same in form as the Greek Γ, but inclined at a different angle, thus, ∠ (see under ALPHABET), and by degrees it was rounded into C. It occupied the same place in the alphabet, and had the same phonetic value,—that of the sonant guttural *g*, the corresponding surd being represented, as in Greek, by K. (See under B for the distinction between sonants and surds.) These two sounds became confused at Rome at an early time—before 450 B.C., and perhaps much earlier. The *k*-sound was lost and the symbol C represented both the *g*-sound, as in *macister*, *lecio*, and the original *k*-sound, as in *censor*, *consul*. The symbol K, however, was not entirely lost; it is found irregularly in inscriptions of all dates down to the times of the empire, and regularly as an initial abbreviation of *Kalendæ*, *Karthago*, *Kæso* (the proper name). In the 3d century B.C., the distinction between the two sounds was revived; but the symbol K was not replaced in ordinary use. C remained as the representative of the surd, losing its original sonant value; while a modification of it (G) was introduced to represent the sonant. The symbol retained its old value only when as the initial letter it represented the names *Gaius* and *Gnæus*,—which, in consequence, are often erroneously written and sounded *Caius* and *Cnæus*. With this changed value the symbol C passed into the languages which are represented by the Latin alphabet. In some of them it has undergone yet further change. Before *e* and *i* in Italian, though still written, it is sounded as *ch*. This change from the guttural to the palatal is the result of assimilation, due to the following vowels. There is no evidence to show that it was established before the 7th century A.D. In France (as commonly in England) *c* before *e* and *i* has the sound of *s*. This is only a further change in the same direction as the Italian; and before *a* in French an original *c* has the sound *sh*, and is spelt *ch*, as in *champ* (*campus*), *chambre* (*camera*). Exceptions to this rule are generally words incorporated into classical French (*i.e.*, the descendant of the old dialect of the Isle de France) from other dialects, as those of Normandy or Picardy, or are introduced from the Italian, as *cavalier*, &c. Our English *ch* (pronounced *tch*) for original *c* (as in *chin* for Old English *cin*, *child* for *cild*) is due probably to Norman influence, but here, as often, it is difficult to differentiate the results of the many disturbing causes which have operated upon our language.

As a numeral, C (for *centum*) denotes 100. In music, placed after the clef, it indicates that the measure is of the value of four crotchets.

CAABA. See KAABA and MECCA.

CABAGAN, a town of Luzon, one of the Philippine Islands, in the province of Cagayan, situated on the N.E. coast. It is the second largest city in the province, and has a population of 11,100.

CABANIS, PIERRE JEAN GEORGE (1757–1808), a distinguished French physiologist, was born at Cosnac in 1757. His father was a lawyer of eminence, and chief magistrate of a district in the Lower Limousin. His education was at first entrusted to the priests, but at the age of ten he was transferred to the College of Brives. He showed great aptitude for study, but his independence of spirit was so excessive that he was almost constantly in a state of rebellion against his teachers, and was finally dismissed from the school. After a year's residence at home he was taken to Paris by his father and left to carry on his studies at his own discretion. He attended classes at the university, and read with particular delight Locke's essay *On the Human Understanding*. Two years had been spent in close and assiduous study, when in 1773 he received the offer of the post of secretary to the prince-bishop of Wilna. He accepted it and passed two years at Warsaw, viewing with disgust and contempt the petty intrigues and jealousies that accompanied the first partition of Poland.

On his return to Paris he devoted himself mainly to poetry, for which he had always a strong inclination. He was intimate with the poet Roucher, and was introduced by Turgot to the society of Mme. Helvetius, where he met such men as Diderot, D'Alembert, D'Holbach, Condillac, Franklin, and Jefferson. About this time he ventured to send in to the Academy a translation of the passage from Homer proposed for their prize, and though his attempt passed without notice, he received so much encouragement from his friends that he contemplated translating the whole of the *Iliad*.

At the earnest desire of his father he relinquished these pleasant literary employments, and resolved to engage in some settled profession. After deliberation he fixed upon that of medicine, and began his studies under Dubreuil. In 1789 his *Observations sur les Hôpitaux* procured him an appointment as administrator of hospitals in Paris. From inclination and from weak health he never engaged much in practice as a physician. His interest lay entirely in the deeper problems of medical and physiological science, and these he investigated with unusual closeness and minuteness. Nor had he quite given up his fondness for literary society; his residence at Auteuil on the outskirts of the capital enabled him still to continue his intercourse with Diderot, Condillac, and others. He had even the pleasure of reading to Voltaire part of his translation of the *Iliad*, and of receiving warm commendation from the veteran critic. But he had long ceased to occupy himself with that work; and in his *Serment d'un Médecin*, which appeared in 1789, he bade a formal adieu to poetry.

In the great political struggle of the time Cabanis espoused with enthusiasm the cause of the Revolution, to which he was attached from principle, and of which the opening prospects were congenial to his active and ardent mind. During the two last years of Mirabeau's life he was intimately connected with that extraordinary man, who had the singular art of pressing into his service the pens of all his literary friends. Cabanis united himself with this disinterested association of labourers, and contributed the *Travail sur l'Education Publique*, a tract which was found among the papers of Mirabeau at his death, and was edited by the real author soon afterwards in 1791. During the illness which terminated his life, Mirabeau confided himself entirely to the professional skill of Cabanis. Of the progress of the malady, and the circumstances attending the death of Mirabeau, Cabanis drew up a very detailed narrative, which is not calculated, however, to impress us with any high idea of his skill in the treatment of an acute inflammatory disease. Condorcet was another distinguished character with whom Cabanis was intimate, and whom he endeavoured, though without success, to save from the destiny in which he afterwards became involved by the calamitous events of the Revolution. Shortly after this he married Charlotte Grouchy, sister to Madame Condorcet and to General Grouchy,—a union which was a great source of happiness to him during the remainder of his life.

After the subversion of the Government of the terrorists, Cabanis, on the establishment of central schools, was named professor of *Hygiène* in the medical schools of the metropolis. Next year he was chosen member of the National Institute, and was subsequently appointed clinical professor. He was afterwards member of the Council of Five Hundred, and then of the Conservative Senate. The dissolution of the Directory was the result of a motion which he made to that effect. But his political career was not of long continuance. A foe to tyranny in every shape, he was decidedly hostile to the policy of Bonaparte, and constantly rejected every solicitation to accept a place under his Government.

For some years before his death his health became gradually more impaired, and he retired from the laborious duties of his profession, spending the greatest part of his time at the chateau of his father-in-law at Meulan. Here he solaced himself with reading his favourite poets, and even had it in contemplation to resume that translation of the *Iliad* which had been the first effort of his youthful muse. The rest of his time was devoted to acts of kindness and beneficence, especially towards the poor, who flocked from all parts to consult him on their complaints. Cabanis died May 5 1808, leaving a widow and a daughter.

A complete edition of Cabanis's works was begun in 1825, and five volumes were published. One of his minor works, *Coup d'œil sur les révolutions et les réformes de la médecin*, has been translated into English. His principal work, *Rapports du physique et du moral de l'homme*, consists in part of memoirs, read in 1796 and 1797 to the Institute, and printed among their Transactions. It is an admirable sketch of physiological psychology, and is replete with information. Psychology is with Cabanis directly linked on to biology, for sensibility, the fundamental fact, is the highest grade of life and the lowest of intelligence. All the intellectual processes are evolved from sensibility, and sensibility itself is a property of the nervous system. The soul is not an entity, but a faculty; thought is the function of the brain. Just as the stomach and intestines receive food and digest it, so the brain receives impressions, digests them, and has as its organic secretion, thought. Alongside of this harsh materialism Cabanis held another principle, the application of which altogether changes his theory. He belonged in biology to the school of Stahl, the vitalist or animist, and in the posthumous work, *Lettre sur les causes premières*, the consequences of this opinion became clear. Life is something added to the organism; over and above the universally diffused sensibility there is some living and productive power to which we give the name of Nature. But it is impossible to avoid ascribing to this power both intelligence and will. In us this living power constitutes the ego, which is truly immaterial and immortal. These results Cabanis did not think out of harmony with his earlier theory, and it is possible that a point of view may be attained whence both appear justified. The *Lettre* was not published till 1824, when it appeared with notes by F. Bérard.

CABARRUS, François (1752-1810), conspicuous in Spanish history as a financier, was born at Bayonne, where his father was a merchant. Being sent into Spain on business he fell in love with a Spanish lady, and marrying her, settled in Madrid. Here his private business was the manufacture of soap; but he soon began to interest himself in the public questions which were ventilated even at the court of Spain. The enlightenment of the 18th century had penetrated as far as Madrid; the king, Charles III., was favourable to reform; and a circle of men animated by the new spirit were trying to infuse fresh vigour into an enfeebled state. Among these Cabarrus became conspicuous, especially in finance. He originated a bank, and a company to trade with the Philippine Islands; and as one of the council of finance he had planned many reforms in that department of the administration, when Charles III. died (1788), and the reactionary Government of Charles IV. arrested every kind of enlightened progress. The men who had taken an active part in reform were suspected and prosecuted. Cabarrus himself was accused of embezzlement, and thrown into prison. After a confinement of two years he was released, created a count, and employed in many honourable missions; he would even have been sent to Paris as Spanish ambassador, had not the Directory objected to him as being of French birth. Cabarrus took no part in the transactions by which Charles IV. was obliged to abdicate and make way for Joseph, brother of Napoleon, but his French birth, and intimate knowledge of Spanish affairs recommended him to the Emperor as the fittest person for the difficult post of minister of finance. In this capacity Cabarrus died (1810). His beautiful daughter Thérése, under the name of Madame Tallien (afterwards Princess of Chimay), played an interesting part in the later stages of the French Revolution.

CABATUAN, a town of the Philippine Islands, in the province of Iloilo, in Panay, situated on the banks of the River Tiguin, which changes from an almost empty channel to an impetuous torrent, so that navigation is frequently impossible. The town, which was founded in 1732, has about 23,000 inhabitants, who are principally engaged in the cultivation of rice and the manufacture of cocoa-nut oil. See Bowring's *Philippine Islands*.

CABAZERA, a town of the Philippine Islands, capital of the province of Cagayan in Luzon, with a population of about 15,000. Tobacco-growing is the most important occupation of the district.

CABBAGE. The parent form of the variety of useful culinary vegetables included under this head is generally supposed to be the wild or sea cabbage (*Brassica oleracea*), a plant found near the sea coast of various parts of England and continental Europe, although Alph. de Candolle considers it to be really descended from the two or three allied species which are yet found growing wild on the Mediterranean coast. In any case the cultivated varieties have departed very widely from the original type, and they present very marked and striking dissimilarities among themselves. The wild cabbage is a comparatively insignificant plant, growing from 1 to 2 feet high, in appearance very similar to the corn mustard or charlock (*Sinapis arvensis*), but differing from it in having smooth leaves. The wild plant has fleshy, shining, waved, and lobed leaves (the uppermost being undivided but toothed), large yellow flowers, elongated seed-pod, and seeds with conduplicate cotyledons. Notwithstanding the fact that the cultivated forms differ in habit so widely, it is remarkable that the flower, seed-pods, and seeds of the varieties present no appreciable difference.

The late Dr Lindley proposed the following classification for the various forms, which includes all yet cultivated:—1. All the leaf-buds active and open, as in wild cabbage and kale or greens; 2. All the leaf-buds active, but forming heads, as in Brussels sprouts; 3. Terminal leaf-buds alone active, forming a head, as in common cabbage, savoys, &c.; 4. Terminal leaf-bud alone active and open, with most of the flowers abortive and succulent, as in cauliflower and broccoli; 5. All the leaf-buds active and open, with most of the flowers abortive and succulent, as in sprouting broccoli. The least variety bears the same relation to common broccoli as Brussels sprouts do to the common cabbage. Of all these forms there are numerous gardeners' varieties, all of which reproduce faithfully enough their parent form by proper and separate cultivation. Under Dr Lindley's first class, common or Scotch kale is a variety which formerly was in extensive cultivation, and is still found in the cottage "kail-yards" or gardens of the Scottish peasantry. It sends up a stout central stem, growing upright to a height of about 2 feet, with close-set, large thick plain leaves of a light red or purplish hue. The lower leaves are stripped off for use as the plants grow up, and used for the preparation of broth or "Scotch kail," a dish at one time in great repute in the north-eastern

districts of Scotland. Tall or German greens, which grow to the height of 4 feet, with bright green very much curled leaves, have largely superseded kale in cultivation. A very remarkable variety of open-leaved cabbage is cultivated in the Channel Islands under the name of the Jersey or branching cabbage. It grows to a height of 8 feet, but has been known to attain double that altitude. It throws out branches from the central stem, which is sufficiently firm and woody to be fashioned into walking-sticks; and the stems are even used by the islanders as rafters for bearing the thatch on their cottage-roofs. Several varieties are cultivated as ornamental plants on account of their beautifully coloured, frizzled, and laciniated leaves. Brussels sprouts, which represent Dr Lindley's second class, are miniature cabbage-heads, about an inch in diameter, which form in the axils of the leaves. They form a tender and delicate table vegetable. The third class is chiefly represented by the common or drumhead cabbage, the varieties of which are distinguished by difference in size, form, and colour. In Germany it is converted into a popular article of diet under the name of *Sauerkraut* by placing in a tub alternate layers of salt and cabbage. An acid fermentation sets in, which after a few days is complete, when the vessel is tightly covered over and the product kept for use with animal food. Cabbages contain a large percentage of nitrogenous compounds as compared with most other articles of food. Their percentage composition is—water, 93·4; albumen, 1·8; starch and dextrin, 3·3; woody fibre, 0·5; and mineral ash, 0·8. Red cabbage is chiefly used for pickling, and the Savoy is a hardy green variety, characterized by its very wrinkled leaves. The Portugal cabbage, or *Couve Tronchuda*, is a variety, the tops of which form an excellent cabbage, while the midribs of the large leaves are cooked like sea-kale. Cauliflower, which is the chief representative of class four, consists of the inflorescence of the plant modified so as to form a compact succulent white mass or head; this is upon the whole the most highly prized cultivated form of the plant, and has been in use from very remote times. Broccoli is merely a variety of cauliflower differing from the other in the form and colour of its inflorescence and its hardiness. Broccoli sprouts, the representative of the fifth class, is a form of recent introduction, and consists of flowering sprouts springing from the axils of the leaves. Kohl-rabi is a peculiar and exceptional variety of cabbage in which the stem, just above ground, swells into a fleshy turnip-like mass. It is much cultivated in certain districts as a food for cattle. The varieties of cabbage, like many other Cruciferous plants, are possessed of anti-scorbutic properties; but unless eaten when very fresh and tender they are difficult of digestion, and have a very decided tendency to produce flatulence.

Several species of palm, from the fact of yielding large sapid central buds which are cooked as vegetables, are known as Cabbage Palms. The principal of these is *Areca oleracea*, but other species, such as the Coco Palm, the *Maximiliana regia*, *Arenga saccharifera*, &c., yield similar edible leaf-buds.

CABBALA AND CABBALISTS. See KABBALA.

CABENDA, or CABINDA, a seaport town of Western Africa, in Lower Guinea, 40 miles north of the mouth of the Zaire, on the right bank of the Bele, in 5° 33′ S. lat., 15° 40′ E. long. From the great beauty of its situation, and the fertility of the adjacent country, it has been called the paradise of the coast. The harbour is well sheltered and commodious, and the trade is considerable. Population about 16,000.

CABET, ÉTIENNE (1788–1856), an active French Communist, was born, the son of a cooper, at Dijon in 1788. He chose the profession of advocate without succeeding in it, but erelong became notable as the persevering apostle of republicanism and communism. He assisted in a secondary way in the Revolution of 1830, and obtained a legal appointment in Corsica under the Government of Louis Philippe; but, being dissatisfied with the moderation of the new rule, he began to attack it even in public, and was dismissed. Elected, notwithstanding, to the Chamber of Deputies, he was prosecuted for his bitter criticism of the Government, and obliged to go into exile in England. On the amnesty of 1839, he returned to France, and attracted some notice by the publication of a badly-written and fiercely democratic history of the Revolution of 1789 (4 vols., 1840), and of a social romance, *Voyage en Icarie*, in which he set forth his peculiar views. These works met with some success among the radical working-men of Paris. An opportunity at length occurred of realizing his schemes. Pressed by his friends, he made arrangements for an experiment in communism on American soil. In his journal, *Le Populaire*, he announced the purchase of a considerable tract of land on the Red River, Texas, and a treaty by which Cabet was made the dictator of an intending colony, and the depositary of all the funds, community of property being the distinctive principle of the society. Accordingly, in 1848, an expedition of 150 sailed to America; but unexpected difficulties arose and the complaints of the disenchanted settlers soon reached Europe. Cabet, who had remained in France, had more than one judicial investigation to undergo in consequence, but was honourably acquitted. In 1849 he went out in person to America, but on his arrival, finding that the Mormons had been expelled from their city Nauvoo, in Illinois, he transferred his settlement thither. There, with the exception of a journey to France, where he returned to defend himself successfully before the tribunals, he remained, the dictator of his little society. In 1856, however, he was expelled, and died the same year at St Louis. He had not the advantages of either birth or eloquence, or even of ability. The little success he obtained was due entirely to the singularity of his opinions, and the straightforward persistency with which he advocated them.

CABEZA DEL BUEY (*i.e.*, bullock's head), a town of Spain, in Estremadura, in the province of Badajoz, and 86 miles E.S.E. from the city of that name. It manufactures woollen cloth, and has a population of 6500.

CABINET, a conventional, but not a legal, term employed to describe those members of the Privy Council who fill the highest executive offices in the State, and who, by their concerted policy, direct the Government, and are responsible for all the acts of the Crown. The Cabinet now always includes the persons filling the following offices, who are therefore called Cabinet Ministers, viz:—The First Lord of the Treasury; the Lord Chancellor, the Lord President of the Council, the Lord Privy Seal, the five Secretaries of State, the Chancellor of the Exchequer, and the First Lord of the Admiralty. The Chancellor of the Duchy of Lancaster, the Postmaster General, the First Commissioner of Works, the President of the Board of Trade, the Chief Secretary for Ireland, the President of the Poor Law Board, and the Vice-President of the Education Committee are sometimes members of the Cabinet, but not necessarily so. Hence the Cabinet must consist of at least eleven members, and it has sometimes included as many as seventeen. But the better opinion appears to be that a large Cabinet is an evil. Mr Disraeli in 1874 acted wisely in restricting the numbers of his colleagues to eleven besides the Prime Minister. When Lord Grenville in 1806 brought Lord Chief Justice Ellenborough into the Cabinet by combining his judicial office with that of Lord President, the appointment was strongly reprobated, and the experiment has never been repeated. The Master-General of the

Ordnance used to have a seat in the Cabinet, and the duke of Wellington sat there for a short time as Commander-in-Chief. Of late years there has been no military officer in the Cabinet, a thing much to be regretted. In a few instances privy councillors of very high standing, as the duke of Wellington, Lord Sidmouth the marquis of Lansdowne, and Lord Russell, have been summoned to the Cabinet without office. There is no constitutional objection to summoning any privy councillor to the Cabinet by command of the sovereign.

The word "Cabinet," or "Cabinet Council," was originally employed as a term of reproach. Thus Lord Bacon says, in his essay *Of Counsel* (xx.), "The doctrine of Italy and practice of France, in some kings' times, hath introduced Cabinet Councils—a remedy worse than the disease;" and, again, "As for Cabinet Councils, it may be their motto *Plenus rimarum sum*." Lord Clarendon—after stating that, in 1640, when the great Council of Peers was convened by the king at York, the burden of affairs rested principally on Laud, Strafford, and Cottington, with five or six others added to them on account of their official position and ability—adds, "These persons made up the Committee of State, which was reproachfully after called the *Juncto*, and enviously then in Court the *Cabinet Council*." And in the Second Remonstrance in January 1642, Parliament complained "of the managing of the great affairs of the realm in *Cabinet Councils*, by men unknown and not publicly trusted." But this use of the term, though historically curious, has in truth nothing in common with the modern application of it. It meant, at that time, the employment of a select body of favourites by the king, who were supposed to possess a larger share of his confidence than the Privy Council at large.[1] Under the Tudors, at least from the later years of Henry VIII., and under the Stuarts, the Privy Council was the Council of State or Government. During the Common-wealth it assumed that name.

The Cabinet Council, properly so called, dates from the reign of William III. and from the year 1693, for it was not until some years after the Revolution that the king discovered and adopted the two fundamental principles of a constitutional Executive Government, namely, that a ministry should consist of statesmen holding the same political principles and identified with each other; and, secondly, that the ministry should stand upon a parliamentary basis, that is, that it must command and retain the majority of votes in the Legislature. It was long before these principles were thoroughly worked out and understood, and the perfection to which they have been brought in modern times is the result of time, experience, and, in part, of accident. But the result is that the Cabinet Council for the time being *is* the Government of Great Britain; that all the powers vested in the sovereign (with one or two exceptions) are practically exercised by the members of this body; that all the members of the Cabinet are jointly and severally responsible for all its measures, for if differences of opinion arise their existence is unknown as long as the Cabinet lasts,—when publicly manifested the Cabinet is at an end; and lastly, that the Cabinet, being responsible to the sovereign for the conduct of executive business, is also collectively responsible to Parliament both for its executive conduct and for its legislative measures, the same men being as members of the Cabinet the servants of the Crown, and as Members of Parliament and leaders of the majority responsible to those who support them by their votes and may challenge in debate every one of their actions. In this latter sense the Cabinet has sometimes been described as a Standing Committee of both Houses of Parliament.

This in reality is the form to which the active governing machinery of the British Constitution has now been brought. It has been ingeniously argued by Mr Bagehot, in his *Essays on the Constitution*, that "the Cabinet is a board of control, chosen by the Legislature, out of the persons whom it trusts and knows, to rule the nation," and that the choice of the Crown and of the Prime Minister, who frames the list of Cabinet Ministers to be laid before the sovereign, is in fact circumscribed and predetermined by the position which a small number of men in each party have acquired in Parliament. No man can long remain a Cabinet Minister who is not in Parliament; and of those who sit in either House of Parliament, but a small proportion have attained to the rank or influence that fits a man to be a Cabinet Minister. This is especially the case in the House of Commons, largely composed of men engaged in various professions; for it is easier to find men of high senatorial rank and experience in the House of Peers than in the other House, because in England members of the Peerage are frequently trained and educated from early life for high office and the public service. The Cabinet, therefore, really originates in the Legislature, though its functions are the functions of executive government, and although it disposes on behalf of the Crown of a vast amount of power, patronage, honours, &c., to which the authority of the Legislature does not extend. The Cabinet has, moreover, one most important power, which it derives entirely from the Crown, namely, that of dissolving the Legislature to which it owes its own existence—though this is in fact no more than an appeal to the nation at large, whose representative the Legislature is. The power of dissolving Parliament is one usually, though not always unreservedly, entrusted by the sovereign to the Prime Minister; but if withheld when solicited, the minister would resign.

Instances are not wanting in our history in which the direct action of the sovereign has overthrown a Cabinet, or prevented a Cabinet from being formed. In 1784 George III. dismissed the Coalition Ministry. In 1807 the king also dismissed Lord Grenville's Cabinet, in the teeth of Lord Erskine's declaration of the high Whig doctrine, that the king had handed over every power of government, and even his own conscience, to his responsible advisers. In these instances the Crown succeeded, and the new Parliament ratified the change. Not so in 1834 when William IV. dismissed Lord Melbourne's Cabinet, placed the duke of Wellington for some weeks in sole possession of all the Cabinet offices, and called Sir Robert Peel to power. In 1812 Lord Moira was defeated in the attempt to form a Cabinet by the refusal of the regent to consent to a change in the household; and in 1839 a similar reason was alleged by Queen Victoria to prevent the accession to office of Sir Robert Peel. But though this step was defended and sanctioned by a minute of the Whig Cabinet of the day, it is now generally regarded as unconstitutional, and the objection was never repeated.

One of the consequences of the close connection of the Cabinet with the Legislature is that it is desirable to divide the strength of the ministry between the two Houses of Parliament. Mr Pitt's Cabinet of 1783 consisted of himself in the House of Commons and seven peers. But so aristocratic a Government would now be impracticable. In Mr Gladstone's large Cabinet of 1868, eight, and afterwards nine, ministers were in the House of Commons and six in the House of Peers. Great efforts were made to strengthen

[1] Thus, under Charles II., in 1671, the king's confidential advisers were Clifford, Arlington, Buckingham, Ashley, and Lauderdale. The initial letters of their names spell the word "Cabal;" and Lord Macaulay affirms that the word cabal was popularly used as synonymous with cabinet. But the word cabal certainly never was applied to any other cabinet: and the cabal itself was not in truth a cabinet at all.

the ministerial bench in the Commons, and a new principle was introduced, that the representatives of what are called the spending departments—that is, the Secretary of State for War and the First Lord of the Admiralty—should, if possible, be members of the House which votes the supplies. Mr Disraeli followed this precedent.

Although the Government of this country is one of extreme publicity, it is to the credit of the good sense and good faith of Englishmen that the deliberations and proceedings of the Executive Government are veiled in impenetrable secrecy, until the moment when the result of them is made known. Beyond the meagre announcement in the *Court Circular* of the bare fact that a Cabinet has been held, and that certain ministers were present, nothing is communicated to the public. Cabinets are usually convoked by a summons addressed to "Her Majesty's Confidential Servants," by direction of the Prime Minister; and the ordinary place of meeting is the Foreign Office, but they may be held anywhere. No secretary or other officer is present at the deliberations of this council. No official record is kept of its proceedings, and it is even considered a breach of ministerial confidence to keep a private record of what passed in the Cabinet, inasmuch as such memoranda may fall into other hands. But on some important occasions, as is known from the *Memoirs of Lord Sidmouth*, the *Correspondence of Earl Grey with King William IV.*, and from Sir Robert Peel's *Memoirs*, published by permission of the Queen, Cabinet minutes are drawn up and submitted to the sovereign, as the most formal manner in which the advice of the ministry can be tendered to the Crown and placed upon record. More commonly, it is the duty of the Prime Minister to lay the collective opinion of his colleagues before the sovereign, and take his or her pleasure on public measures and appointments. The sovereign never presides at a Cabinet, and at the meetings of the Privy Council, where the sovereign does preside, the business is purely formal. It has been laid down by some writers as a principle of the British Constitution that the sovereign is never present at a discussion between the advisers of the Crown; and this is, no doubt, an established fact and practice. But like many other political usages of this country it originated in a happy accident. King William and Queen Anne always presided at weekly Cabinet Councils. But when the Hanoverian princes ascended the throne, they knew no English, and were barely able to converse at all with their ministers; for George I. or George II. to take part in, or even to listen to, a debate in council was impossible. When George III. mounted the throne the practice of the independent deliberations of the Cabinet was well established, and it has never been departed from. In no other country has this practice been introduced, and perhaps this is one reason why in many instances constitutional government has failed to take root.

Differences of opinion, of course, occur in all bodies of men, and arguments are frequently presented with greater ability and temper in private than in public debate. These differences are decided in the Cabinet, as in all committees of council, by the majority of votes, and the rule holds good in all of them that "no man shall make publication of how the minority voted." The vote once taken and the question decided, every member of the Cabinet becomes equally responsible for the decision, and is equally bound to support and defend it. A decided difference of opinion cannot be persisted in or publicly expressed without withdrawing from the Cabinet, as when Mr Gladstone quitted Sir Robert Peel's administration upon the proposal to endow Maynooth. Hence it arises that resignations, or threats of resignation, are much more common than the public imagine; and a good deal of tact and management is continually exercised in reconciling these differences. A serious "division in the Cabinet" is, as is well known, an infallible sign of its approaching dissolution. There are cases in which a minister has been dismissed for a departure from the concerted action of his colleagues. Thus, in 1851, Lord Palmerston having expressed to the French ambassador in London his unqualified approbation of the *coup d'état* of Louis Napoleon against the Assembly, when the Cabinet had resolved on observing a strict neutrality on the subject, Lord Russell advised Her Majesty to withdraw from Lord Palmerston the seals of the Foreign Department, and his lordship never again filled that office.

A clause was introduced into the Act of Settlement of 1705 requiring all Acts of State to be transacted in the Privy Council and signed by all the members present. This provision was found to be inconvenient, and was repealed two years afterwards. According to modern usage only one kind of public document is signed by all the members of the Cabinet, as privy councillors, and that is the order for general reprisals which constitutes a declaration of war. Such an order was issued against Russia in 1854, and was signed by all the members of Lord Aberdeen's Cabinet.

Upon the resignation or dissolution of a ministry, the sovereign exercises the undoubted prerogative of selecting the person who may be thought by the Court most fit to form a new Cabinet. In several instances the statesmen selected by the Crown have found themselves unable to accomplish the task confided to them. But in more favourable cases the minister chosen for this supreme office by the Crown has the power of distributing all the political offices of the Government as may seem best to himself, subject only to the ultimate approval of the sovereign. The First Minister is therefore in reality the author and constructor of the Cabinet; he holds it together; and in the event of his retirement, from whatever cause, the Cabinet is really dissolved, even though its members are again united under another head, as was the case when Lord Melbourne succeeded Lord Grey in 1834, and when Mr Disraeli succeeded Lord Derby in February 1868. Each member of the Cabinet, in fact, holds office under the First Lord of the Treasury, and in the event of resignation it is to him that the announcement of such an intention should be made.

The best account of the Cabinet council and of the other executive machinery of the constitution is to be found in Mr Alpheus Todd's *Essay on Parliamentary Government in England* (2 vols. 8vo, 1867-69), where all the authorities are collected—Hallam, May, John Austin, Lord Macaulay—and a vast quantity of political information, compiled from debates and bearing on this subject. Mr Bagehot's *Essay on the English Constitution* contains an ingenious comparison, or rather contrast, between the British Cabinet and the administrative mechanism of the United States of America. (H. R.)

CABIRI (Κάβειροι), in Mythology, usually identified with the Dioscuri (Castor and Pollux), in common with whom they were styled *μεγάλοι Θεοί* (*magni Dii*), and had the power of protecting life against storms at sea, the symbol of their presence being the St Elmo fire. The worship of the Cabiri was local and peculiar to the islands of *Lemnos*, Imbros, and Samothrace, extending also to the neighbouring coast of Troy, in which places it appears to have been inherited from a primitive Pelasgic population. It was, however, in Samothrace that this worship attained its chief importance, coming first into notice apparently after the Persian war, and from that time extending its influence down into the Roman period. The point of attraction was in the religious Mysteries, initiation into which was sought for, not only by large numbers of pilgrims, but also by such persons of distinction as Philip and Olympias—the parents of Alexander, his successor Lysimachus, Arsinoë, and those Roman commanders whose duties led them to that quarter.

What the rites were in which the Mysteries consisted is unknown, and it is therefore impossible to say how far they may have been organized on the model of the Mysteries of Eleusis, though it is clear that Athens took a considerable part in being the first to extend the influence of the Samothracian Mysteries. Initiation included also an asylum or refuge, if required, within the strong walls of Samothrace, for which purpose it was used among others by Arsinoë, who afterwards caused to be erected there (276–247 B.C.), to record her gratitude, a monument, the ruins of which were explored in 1874 by an Austrian archæological expedition (*Untersuchungen auf Samothrake*, by Conze, Hauser, and Niemann, Vienna, 1875).

In Lemnos an annual festival was held, lasting nine days, during which all the fires in the island were extinguished and fresh fire brought from Delos. From this and from the statement of Strabo (x. 437), that the father of the Cabiri was Camillus, a son of the god Hephæstus, it has been thought that the Cabiri must have been, like the Curetes, Corybantes, and Dactyls, dæmons of volcanic fire. But this is very uncertain. In Lemnos they fostered the growth of the vine and fruits of the field, and from their connection with Hermes in Samothrace, it would seem that they had also aided the fertility of cattle. Both the names and the number of the Cabiri are doubtful. On late authority they are given as *Axieros*, *Axiokersa*, and *Axiokersos*, with a fourth called *Kadmilos* or *Kasmilos*; but in the usual tradition they were *Dardanos*, *Jasion*, and *Harmonia*. Jasion, who was a favourite of the goddess Demeter, instituted the Mysteries. Harmonia married Cadmus of Thebes, whose name is to be recognized in Kadmilos, one of the Cabiri. On the other hand it has been argued that there were only two Cabiri, Dardanus and Jasion, corresponding as deities to the Greek Poseidon and Apollo, or Uranus and Gæa, *i.e.*, sky and earth. On these points, the statements of ancient writers are not only few but generally irreconcilable with each other. On Etruscan bronze mirrors representations of what are called the Cabiri frequently occur, consisting of two youthful figures, sometimes with the addition of a female figure, apparently their sister; sometimes there are three brothers. This subject is dealt with in detail by Gerhard in his *Etruskische Metall-Spiegel*.

CABLE, a rope or chain used for connecting a ship with her anchor. Chain cables are generally used, but on account of their weight they are unsuitable for mooring in very deep water, when several lengths of cable would be hanging at the "hawse pipe;" and they cannot be used, also on account of their weight, when it is required to lay an anchor out at some distance from the ship. Hempen cables are, therefore, supplied to all ships as well as chain cables. For sizes, number, and lengths of cables carried by ships of the Royal Navy and required by Lloyd's rules to be supplied to merchant ships, see article ANCHOR.

The length of a chain cable is 100 fathoms, and that of a hempen cable 101 fathoms. The term "a cable's length," by which the distance of vessels from each other is usually given in nautical parlance, is understood to mean 100 fathoms, or 200 yards. Cables are sometimes made of common chain, but the best and most approved are made of stud-link chain, as shown in fig. 1, which gives the relative proportions of the various parts. Cables are made in lengths of 12½ fathoms, connected together by "joining shackles," as shown at D. Each length is "marked" by a piece of iron-wire being twisted round the stud of one of the links, the wire being placed on the first stud inside the first shackle,—*i.e.*, the stud nearest to the shackle on the side remote from the anchor,—on the second stud inside the second shackle, and so on, so that the length of cable which is out may always be known. For instance, if the mark is on the sixth stud inside the first inboard shackle, it is known that six lengths, or 75 fathoms, of cable are out, measuring from that shackle. In joining the lengths together the round end of the shackle should be placed towards the anchor. The end links of each length C, C are made without studs in order to receive the shackles, and it is necessary to make them of iron of greater diameter than that used for the stud links, in order to keep them of equal strength. The stud keeps the link from collapsing, and increases its strength considerably.

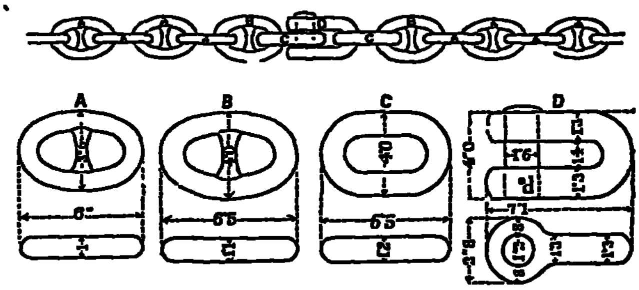


FIG. 1.—Stud-link Chain.[1]

The next links B, B in their turn have to be enlarged to enable them to take the increased size given to the links C, C. It will be observed from the sketch of the shackle D that the pin is made oval, its greater diameter being in the direction of the strain. The pin of the shackle which attaches the cable to the anchor, and is called the "anchor shackle" in distinction from the "joining shackles," may project and be secured by a forelock; but as any projection would be detrimental when the chain is running out (sometimes with great rapidity) through the hawse pipes, the pins of the joining shackles are made as shown, and are secured by a small pin *d*. This small pin is kept from coming out by being made a little short, so that a lead pellet may be driven in at either end to fill up the holes in the shackle, which are made with a groove, so that as the pellets are driven in they expand or dovetail, and thus keep the small pin secure in its place.

The cables are stowed in the chain lockers, the inner ends being firmly secured to the ship by a "slip." This is done to render it impossible for the cable to run out and be lost accidentally, the slip being provided so that the cable may be let go without difficulty if stress of weather or any other cause renders such a proceeding imperative. It is necessary to fit one or two swivels in each cable to avoid turns being taken in it as the ship swings. When a ship is moored with two anchors the cables are attached to a mooring swivel (fig. 2); if this is not done the cables get entwined around each other, forming what is termed a "foul hawse," which is a troublesome thing to clear.

The cable is hove up in large vessels by a capstan, and in small ones by a windlass. It is brought directly to the capstan, the inner end passing to the deck pipe, and thence to the chain lockers; or it is brought in by means of a messenger, which is an endless chain passing round the capstan and a roller on each side of the deck near the hawse pipes. The cable is stoppered to the messenger by rope or iron nippers, and as the messenger goes round with the capstan the cable is brought in, the nippers being shifted as required. Messengers are now almost entirely superseded by the improved make of capstans.

Various means for checking the cable as it is running out, and for holding it, have been devised. The old-

[1] The dimensions marked in the figure are those for one-inch chains and signify so many diameters of the iron of the common links,—these forming a scale for all sizes.

fashioned plan is to fit a strong iron lever called a "compresser" under the deck pipe, fixed at one end in such a position that when the other end is hove round by a tackle the cable will be jammed between the compresser and the lower edge of the pipe. In place of compressers, or to act in conjunction with them, several kinds of stoppers have been used, fitted either at the deck pipes, or just inside the hawse pipes; those patented by Harfield and Co. find the most favour in the Royal Navy, but the compressers are

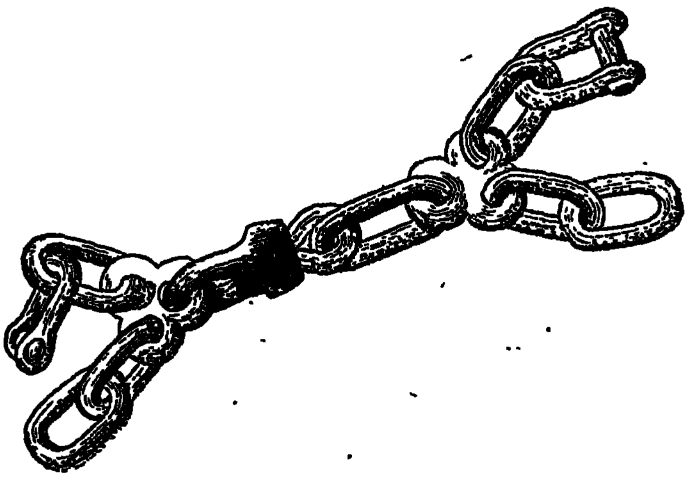

FIG. 2.—Mooring Swivel.

almost invariably fitted with them. Ships are generally held when "riding at anchor" by one or two turns of the cable being taken round the "riding bitts," which are strong structures of iron or wood, placed for this purpose near the hawse pipes. "Stopper bolts"—*i.e.*, ring-and-eye bolts, placed in the deck forward—are also fitted, to which the cable may be secured while the turns are being put on or taken off the riding bitt, while the mooring swivel is being attached, or at other times. (T. M.)

CABOT, SEBASTIAN,[1] the renowned navigator, and contemporary of Columbus, was the son of John Cabot, a Venetian merchant, and was born in Bristol, England, while his father was a resident of that city. On the disputed question of his birthplace, Richard Eden (*Decades of the New World*, fol. 255) says Sebastian told him that, when four years old, he was taken by his father to Venice, and returned to England while still very young, "whereby he was thought to have been born in Venice." Stow, in his *Annals*, under the year 1498, styles "Sebastian Gaboto a Genoas sonne, borne in Bristow." Galvano and Herrera also give to England the honour of his nativity. Neither the year of his birth nor that of his death can be stated with precision; conjecture fixes the former event in about 1476. No instructive details of his early life, until he had passed his twentieth year, can now be recovered.

The discoveries of Columbus infused into young Sebastian an ardent desire to emulate his brilliant achievements. Henry VII. resolved to enter the new field of maritime discovery, which had already rewarded Spain with the Antilles; and the Cabots having proposed to the king the project of shortening the voyage to India by sailing west, to them was confided its execution.

The first patent was granted March 5, 1496 (11th Henry VII.), to "John Gabote, citizen of Venice; to Lewes, Sebastian, and Santius, sonnes of the said John." It empowered them to seek out, subdue, and occupy, at their own charges, any regions which before had "been unknown to all Christians." They were authorized to set up the royal banner, and possess the territories discovered by them as the king's vassals. Bristol was the only port to which they were permitted to return; and a fifth part of the gains of the voyage was reserved to the Crown. The discoverers were vested with exclusive privilege of resort and traffic.

With respect to Lewes and Santius, the chronicles are silent. John and Sebastian sailed from Bristol in the "Matthew" in the following year (1497), and, as now seems probable, returned to England after the first discovery had been made (see BRISTOL, p. 350). There is in the account of the Privy Purse expenses of Henry VII. the following entry:—"10th August 1497. To him that found the New Isle, £10."

Although it is probable that the Island of Newfoundland was discovered in this voyage, a careful scrutiny of the various maps and chronicles sustains the belief that the Cabots saw the mainland of America before any other,—the term *Terra primum visa* having been used to distinguish the continent, or what was believed to form a part of it. The relation of Sebastian (see Hakluyt, 111, p. 7) does not warrant the inference that the first land seen was an island.

The most precise account of the discovery is from a map drawn by Sebastian Cabot, and engraved in 1549 by Clement Adams, which is known to have hung in Queen Elizabeth's gallery at Whitehall. The notice runs as follows:—"In the year of our Lord 1497, John Cabot, a Venetian, and his son Sebastian, discovered that country which no one before his time had ventured to approach, on the 24th of June, about five o'clock in the morning. He called the land *Terra primum visa*, because, as I conjecture, this was the place that first met his eye in looking from the sea. On the contrary, the island which lies opposite the land he called the island of St John,—as I suppose, because it was discovered on the festival of St John the Baptist."

On Sebastian Cabot's map of 1544, the original of which is in the Geographical Cabinet of the Imperial Library at Paris (see fac-simile in Jomard's *Monuments de la Géographie*), nothing is designated above the sixtieth parallel. *Prima tierra vista* is delineated between 45° and 50°, with the island St Juan (corresponding with Prince Edward), within the great gulf at the embouchure of what is plainly the St Lawrence. The authenticity of the map being accepted, the "land first seen" could be no other than the coast of Nova Scotia, or island of Cape Breton.

A second "patent" to John Cabot, dated 3d February 1498, authorized him to take six English ships, of not more than 200 tons, in any port in the realm, "and them convey and lede *to the lande and isles* of late found by the said John in oure name and by oure commandment." Before the expedition was ready, John Cabot died, and Sebastian, with a fleet of five vessels, sailed from Bristol in May 1498. It is believed that this is the voyage referred to by Peter Martyr, Gomara, Fabyan, and by Sebastian himself in his letter to Ramusio. Cabot, upon falling in with the coast, ascended it as high as latitude $67\frac{1}{2}°$, probably passing into Hudson's Bay. He persevered in the effort to find an open channel to India, *until* his sailors, appalled by the danger of navigating the ship among icebergs, broke out in open mutiny and compelled him to turn back. He then retraced his course, pausing at Baccalaos to refit; and, after examining the coast as far south as 38°, returned to England. Sebastian took with him in this voyage three hundred men, with the purpose, as Gomara states, of colonizing the newly-found regions. Thevet, French cosmographer, relates that Cabot landed these emigrants where the cold was so intense that nearly the whole company perished, although it was in July. Cabot brought to England three native inhabitants of the countries he had visited; his great achievement was the discovery of eighteen hundred miles of sea-coast of the North American continent.

[1] Gabote, Patent of 1496; Kabotto, Patent of 1498; Cabote, Eden; Gaboto, Gomara.—*Stow*.

Except the vague report of a voyage undertaken by him in 1499, nothing more appears relative to Sebastian until 1512, when he is found living at Seville, engaged in revising the Spanish king's maps and charts. The death of Ferdinand put an end to a design to renew the search for a north-west passage to Cathay, and Cabot, who was to have commanded, returned to England. In 1517 he undertook, with Sir Thomas Perte, another voyage,—whether of discovery or conquest in Spanish America is uncertain. In 1518 Sebastian revisited Spain, and was appointed pilot-major. After the conference of Badajos, a squadron was fitted out under Cabot to pursue Spanish discovery in the Pacific. It set sail in August 1526, but some of his chief officers having spread disaffection in the fleet, Cabot abandoned the original plan as impracticable, and put into the La Plata. He sailed up this river 350 leagues, built a fort at one of the mouths of the Parana, which stream he ascended in boats, and also penetrated some distance up the Paraguay. Failing to obtain the aid he solicited, and weakened by the assaults of the natives, Sebastian was forced to leave the coast for Spain.

He now, for the second time, returned to England, and notwithstanding a demand by the emperor that "he might be sent over to Spain," settled at Bristol. Edward VI., in 1549, granted the now aged seaman a pension of two hundred and fifty marks. Hakluyt states that the office of Grand Pilot of England was created for him. It was at this period that he explained to the king the phenomenon of the variation of the needle. He was active in promoting the expedition of 1553 to Russia, the success of which gave him the life appointment of Governor of the Muscovy Company.

Cabot is supposed to have died in London, in 1557, sixty-one years subsequent to the date of his first commission from Henry VII., and not far from eighty years old. The place of his burial is unknown, and we are indebted to Eden for the death-bed scene of this intrepid navigator, who saw the American continent before Columbus or Amerigo Vespucci. His character is extolled by contemporaries, and was distinguished for lofty courage and unflagging perseverance in the execution of his designs. Few lives exhibit such incessant activity in the pursuit of an idea. The maps and discourses drawn and written by himself would, if in existence, have shed much light on an illustrious career; but, with the exception of a map said to have been recovered in Germany, and another existing in France, no trace of them remains. The memoir by Richard Biddle, London and Philadelphia, 1831, though faulty in arrangement, is still the best.

CABRA, a town of Spain, in the province of Cordova, about 28 miles S.E. of that city, situated in a fertile valley near the source of the river of the same name. It contains a cathedral church (de la Asuncion) which was formerly a mosque, and has also a theatre, a hospital, a college, and several monasteries. There still remains a part of its old castle called the Tower of Homage; and the abyss into which Don Quixote's Knight del Bosque precipitated himself is pointed out. The fields of clay in the neighbourhood afford materials for a considerable trade in bricks and pottery; and there is an abundant supply of wine, vinegar, oil, and flour from the surrounding districts. The manufacture of coarse linen, woollen, and hempen stuffs is considerable. There are some interesting Moorish remains to be seen in the town and suburbs. Cabra is a town of great antiquity and is identified with the Bæbro or Ægabro of Pliny, which was probably of Punic origin. It was delivered from the Moors by Ferdinand III. in 1240, and entrusted to the order of Calatrava, but in 1331 it was recaptured by the king of Granada. In the reign of Henry IV. it was bestowed on the count of Baena. For several centuries it was the seat of a bishop. Population 11,076.

CABUL, or KÂBUL, in modern days the capital of AFGHANISTAN (*q. v.*) The city stands on the right bank of the river called after it, on the fork made by the junction of the Loghar River, where the productive plain, which extends north to the foot of Hindu Kush, narrows rapidly into the gorges from which the streams issue. The city stands in 34° 30½' N. lat., 69° 6' E. long., at an altitude of 6396 feet above the sea.

Cabul is about 3 miles in circuit; it was formerly walled, but now is not so. The mountains surround it pretty closely except where the plain opens to the N.E. It is triangular in form, the Bâlâ-Hissâr or Acropolis, in which the Amir resides, forming the S.E. angle, and rising about 150 feet above the plain. The old wall had seven gates, of which two alone remain, viz., the Lahori and the Sirdar.

The city is divided into six *mahalas* or quarters, and these again into *kuchas* or sections, which are enclosed and have gates. In tumult these enclosures form small separate fortresses. The streets hardly merit the name, and nowhere could admit wheel carriages; they are narrow passages, frightfully dirty after rain. The houses are of sun-dried brick and wood, seldom more than two stories in height. There are no public buildings of any moment; some mosques are spacious, but none have any magnificence. There are thirteen or fourteen sarais for foreign traders, but they bear no comparison with those of Persia. The public baths lack cleanliness, and the odour of the filth which is used as fuel is most offensive. The greatest ornament of the city was the arcaded and roofed bazaar called *Chihâr Châtâ*, ascribed to Ali Mardân Khân, a noble of the 17th century, who has left behind him many monuments of his munificent public spirit both in Cabul and in Hindustan. Its four arms had an aggregate length of about 600 feet, with a breadth of 30. The display of goods was remarkable, and in the evening it was illuminated. This edifice was destroyed by Sir G. Pollock on evacuating Cabul, as a memento of the treachery of the city. The several crafts, such as saddlers, drapers, braziers, armourers, congregate together, as is usual in the East and to some extent in the south of Europe. Itinerant traders also parade the bazaars, each with his peculiar cry. The old-clothesman of London is represented by the Moghul of Cabul, with his cry of "Old bullion, old clothes!"

Including the Bala Hissar, Cabul contains about 9000 houses, giving a probable population of 50,000 to 60,000. In summer the population is more dense. Without the limits of the old city to the westward is the fortified quarter of Chandol, once a detached village, now a large suburb occupied by the Kizilbashes (see AFGHANISTAN), and containing 1500 to 2000 houses. It has independent bazaars, baths, mosques, &c.

The river of Cabul is traditionally said to have several times flooded or swept away the city. There is but one bridge within the city limits, but there are others above and below in the vicinity. The city is well supplied with water, chiefly by canals drawn from the two rivers, and the streets are frequently intersected by covered aqueducts. There are also many wells, water being found at moderate depth throughout the valley.

Though there is some malarious influence in autumn from the marshy ground north of the city, Cabul is on the whole healthy. In addition to good water it has at most seasons a fine atmosphere, and an excellent supply of food. The children are chubby and ruddy. Vast supplies of fruit of fine quality are brought into the markets from the gardens of the Koh-daman and adjoining valleys. And the shops for the sale of fruit, fresh and dried, are a notable feature in the bazaars.

Cemeteries are numerous in the vicinity, including places of Jewish and common burial. One of the graveyards near

the shrine called Shâh Shahîd contains a tomb bearing in Roman characters the following inscription :—"*Here lyes the body of* Joseph Hicks, *the son* of Thomas Hicks *and* Edith, *who departed this lyfe the eleventh of October* 1666." An annual day in spring is appropriated to visiting the tombs, as in continental Europe. The graves are sprinkled, garlands placed, and small repairs executed.

Many sacred shrines are interspersed among the cemeteries and gardens. The gardens are often on acclivities, formed into terraces, supplied with springs, and abounding in song-birds. Both shrines and gardens are greatly resorted to by the Cabulis, who are passionately fond of this kind of recreation. Most of the roads are bordered by running waters, and shadowed by mulberry, willow, or poplar trees. The tomb of the illustrious Sultan Baber stands about a mile to the west of the city in a singularly charming spot, on a slope spreading before the sun. The grave is marked by two erect slabs of white marble. Near him lie several of his wives and children; the garden has been formerly enclosed by a marble wall; a clear stream waters the flower-beds. From the hill that rises behind the tomb there is a noble prospect of his beloved city, and of the all-fruitful plain stretching to the north of it.

The geographical position of Cabul, in a tolerably open country intervening between the passes which lead to India on the one side, and those which lead to Turkestan on the other, is highly favourable to trade. Baber exalts the importance of its traffic in his day, saying that the products of Khorasan, Rûm (Turkey), Babylonia, and China were all to be found there. People in easy circumstances are numerous. The presence of a court and a considerable military force contributes to the bustle of the place, and imparts animation to many trades. But the people do not excel in any handicraft or manufacture.

Cabul is believed to be the *Ortospanum* or *Ortospana* of the geographies of Alexander's march, a name conjectured to be a corruption of *Urddhasthâna*, "high place." But the actual name is perhaps also found as that of a people in this position (Ptolemy's *Kabolitæ*), if not in the name of a city apparently identical with Ortospana, *Carura*, in some copies read *Cabura*. It was invaded by the Arabs as early as the thirty-fifth year of the Hegira, but it was long before the Mahometans effected any lasting settlement. In the early Mahometan histories and geographies we find (according to a favourite Arabic love of jingle) *Kâbul* and *Zâbul* constantly associated. Zâbul appears to have been the country about Ghazni. Cabul first became a capital when Baber made himself master of it in 1504, and here he reigned for fifteen years before his invasion of Hindustan. In modern times it became a capital again, under Timur Shah (see AFGHANISTAN), and so has continued both to the end of the Durrani dynasty, and under the Barakzais, who now reign. (H. Y.)

CABUL (Kâbul), is also the name of the province including the city so called. It may be considered to embrace the whole of the plains called Koh-daman and Beghram, &c., to the Hindu Kush northward, with the Kohestan or hill country adjoining so far as it is in actual subjection to the Amir's authority. Eastward it extends to the border of Jalâlâbâd at Jagdalak; southward it includes the Loghar district, and extends to the border of Ghazni; north-westward it includes the Paghman hills, and the valley of the upper Kâbul River, and so to the Koh-i-Baba. Roughly it embraces a territory of about 100 miles square. Wheat and barley are the staple products of the arable tracts. Artificial grasses are also much cultivated, and fruits largely, especially in the Koh-daman. A considerable part of the population spends the summer in tents. The villages are not enclosed by fortifications, but contain small private castles or fortalices. The revenue of Cabul province has been stated at £180,000.

For the CABUL RIVER, see fully under AFGHANISTAN.

CACAO. See COCOA.

CACERES, the capital of the province of the same name in Estremadura, in Spain, 20 miles south of the Tagus, and 24 miles west of Truxillo, on a ridge of hills which stretch from east to west. It is the residence of the bishop of Corias, and contains a handsome episcopal palace, as well as a public school, a college, and several charitable institutions. The monastery and college of the Jesuits was one of the finest in the kingdom, but has been secularized and converted into a hospital. In the neighbourhood are large gardens, well-cultivated fields, and extensive pasture grounds; while in the town are oil and fulling mills, soap-works, tanneries, and lime-kilns. There is also some trade in wool. Caceres occupies the site of the ancient *Castra Cæcilia*, and was a place of some importance both under the Romans and under the Moors. There are several fine specimens of the domestic architecture of the Middle Ages, such as the houses of the duke of Abrantes, the count de la Torre, and the count de los Carbajales. The bull-ring, a modern structure of granite, is one of the most remarkable buildings of its kind in Spain. Population, 13,466.

CACHAO, or, as it is variously spelled, KACHO, KECHO, HECHO, or KESHO, formerly known as Donk-king and now officially as Bacthian or Bac-king, is the largest city of Anam, and the capital of the province of Tonquin. It is situated on the west side of the Tonquin River, about eighty miles from the sea, in 105° 35′ E. long., 21° N. lat. It is of great extent. The principal streets are wide and airy, and for the most part are paved with bricks and small stones, but the others are narrow and ill paved. Most of the houses are constructed of mud or sun-burned bricks and timber, and thatched with leaves, straw, or reeds, and are generally one story in height. The public edifices are spacious, particularly the royal palace, which is several miles in circuit, and is surrounded by high walls. Besides this palace there are to be seen the ruins of one still more magnificent, said to have been six miles in circumference. Cachao is a place of some commercial resort; its imports are long cloths, chintz, arms, pepper, and other articles, which are exchanged for gold and manufactured goods, namely, beautiful silks and lackered ware, which last is generally reckoned superior to any in the East. The English factory, which stood on the banks of the river north of the city, and that of the Dutch, south of it, have long been withdrawn. Cachao is peculiarly liable to fires; and to prevent or extinguish these, the city is governed by a rigid police, and divided into wards. Fires for domestic use are only permitted during certain hours of the day. About the middle of the 18th century the city was nearly burnt to the ground by a conflagration, which was the work of incendiaries. In 1873 François Garnier, the famous French explorer, with an expedition of two hundred men and two ships, having come into collision with the authorities, took possession of the city after capturing the fort of Hanoi, which was constructed on European principles and defended by a large garrison. Not long after he was assassinated by the natives; but his victory led to a treaty between the French Government and the Anamese, by which the port is declared open to the flags of all nations.

CACHEO, or CACHAO, a town of Western Africa in Senegambia, in the land of the Papels, a few miles inland from the mouth of the River Cachao or San Domingo. It is a fortified post of the Portuguese, and carries on a trade in gold dust and ivory. Population 15,000.

CACHOEIRA, a town of Brazil, in the province of Bahia, and 62 miles N.W. from the city of that name, is situated on the River Paraguassu, which is subject to

heavy floods. It contains a town-house, a prison, a convent of Carmelites, and some five or six churches, and carries on an active trade in tobacco, coffee, and sugar. Population 15,000.

CACONGO, a small kingdom of Western Africa, separated from Congo by the river Zaire. The surface is mountainous but fruitful, the climate healthy though unsuited for Europeans. A strong tendency to adopt European customs and conveniences is displayed by the inhabitants, who carry on a considerable trade at the seaport towns of Mallemba and Cabinda. The capital is Kinguela.

CACTUS. This word, applied in the form of κάκτος by the ancient Greeks to some prickly plant, was adopted by Linnæus as the family title of a group of curious succulent or fleshy-stemmed plants, most of them prickly and leafless, some of which produce beautiful flowers, and are now so popular in our gardens that the name has become familiar. As applied by Linnæus, the name *Cactus* is almost conterminous with what is now regarded as the natural order *Cactaceæ*, which embraces several modern genera. It is one of the few Linnæan generic terms which have been entirely set aside by the names adopted for the modern divisions of the group.

The *Cacti* may be described in general terms as plants having a woody axis, overlaid with thick masses of cellular tissue forming the fleshy stems. These are extremely various in character and form, being globose, cylindrical, columnar, or flattened into leafy expansions or thick joint-like divisions, the surface being either ribbed like a melon, or developed into nipple-like protuberances, or variously angular, but in the greater number of the species furnished copiously with tufts of horny spines, some of which are exceedingly keen and powerful. These tufts show the position of buds, of which, however, comparatively few are developed. The stems are in most cases leafless, using the term in a popular sense; the leaves, if present at all, being generally reduced to minute scales. In one genus, however, that of *Pereskia*, the stems are less succulent, and the leaves, though rather fleshy, are developed in the usual form. The flowers are frequently large and showy, and are generally attractive from their high colouring. In one group, represented by *Cereus*, they consist of a tube, more or less elongated, on the outer surface of which, towards the base, are developed small and at first inconspicuous scales, which gradually increase in size upwards, and at length become crowded, numerous, and petaloid, forming a funnel-shaped blossom, the beauty of which is much enhanced by the multitude of conspicuous stamens which with the pistil occupy the centre. In another group, represented by *Opuntia*, the flowers are rotate, that is to say, the long tube is replaced by a very short one. At the base of the tube, in both groups, the ovary becomes developed into a fleshy (often edible) fruit, that produced by the *Opuntia* being known as the prickly pear or Indian fig.

The principal modern genera are ranged under two subdivisions, which are separated by the differences in the flower-tube just explained. Those with long-tubed flowers, the *Cacteæ tubulosæ*, form the genera *Melocactus*, *Mammillaria*, *Echinocactus*, *Cereus*, *Pilocereus*, *Echinopsis*, *Phyllocactus*, *Epiphyllum*, &c.; while those with short-tubed flowers, the *Cacteæ rotatæ*, are referred to *Rhipsalis*, *Opuntia*, *Pereskia*, and one or two of minor importance. These plants, whether viewed as the *Cactus* family or the natural order *Cacteæ* or *Cactaceæ*, belong almost entirely, if not exclusively, to the New World; but some of the Opuntias have been so long distributed over certain parts of Europe, especially on the shores of the Mediterranean and the volcanic soil of Italy, that they appear in some places to have taken possession of the soil, and to be distinguished with difficulty from the aboriginal vegetation. The habitats which they affect are the hot dry regions of tropical America, the aridity of which they are enabled to withstand in consequence of the thickness of their skin, and the paucity of evaporating pores or stomates with which they are furnished,—these conditions not permitting the moisture they contain to be carried off too rapidly. Occurring thus as they do in situations where ordinary vegetation could not exist, they may be considered as one of the means which nature has provided for the support of man and animals where other means of subsistence fail. The stems are filled with wholesome though insipid fluid, and the succulent fruit are not only edible but agreeable. In fevers the fruits are freely administered as a cooling drink, and when bruised are regarded as a valuable remedy for the cure of ulcers. The Spanish Americans plant the Opuntias around their houses, where they serve as impenetrable fences.

MELOCACTUS, the family of Melon-thistle or Turk's-cap Cactuses, contains, according to Labouret, a monographer of the order, about thirty species, which inhabit chiefly the West Indies, Mexico, and Brazil, a few extending into New Granada. The typical species, *M. communis*, forms a succulent mass of roundish or ovate form, from 1 foot to 2 feet high, the surface divided into numerous furrows like the ribs of a melon, with projecting angles, which are set with a regular series of stellated spines,—each bundle consisting of about five larger spines, accompanied by smaller but sharp aculei or bristles,—and the tip of the plant being surmounted by a cylindrical crown called a cephalium, 3 to 5 inches high, composed of reddish-brown acicular bristles, closely packed with cottony tomentum. At the summit of this crown the small rosy-pink flowers are produced, half protruding from the mass of wool, and these are succeeded by small red berries. These strange plants usually grow in rocky places with little or no earth to support them; and it is said that in times of drought the cattle resort to them to allay their thirst, first ripping them up with their horns and tearing off the outer skin, and then devouring the moist succulent parts. The fruit, which has an agreeably acid flavour, is frequently eaten in the West Indies. The *Melocacti* are distinguished by the distinct cephalium or crown which bears the flowers.

MAMMILLARIA.—This group, which comprises nearly 300 species, mostly Mexican, with a few Brazilian and West Indian, is called Nipple Cactus, and consists of globular or cylindrical succulent plants, whose surface instead of being cut up into ridges with alternate furrows, as in *Melocactus*, is broken up into teat-like cylindrical or angular tubercles, spirally arranged, and terminating in a radiating tuft of spines which spring from a little woolly cushion. The flowers issue from between the mammillæ, towards the upper part of the stem, often disposed in a zone just below the apex, and are either purple, rose-pink, white, or yellow, and of moderate size. The spines are variously coloured, white and yellow tints predominating, and from the symmetrical arrangement of the areolæ or tufts of spines they are very pretty objects, and are hence frequently kept in drawing-room plant cases.

ECHINOCACTUS is the name given to the group bearing the popular name of Hedgehog Cactus. It comprises some 200 species, of which more than half are natives of Mexico, and the rest are scattered through South America, extending as far south as Buenos Ayres. They have the fleshy stems characteristic of the order, these being either globose, oblong, or cylindrical, and either ribbed as in *Melocactus*, or broken up into distinct tubercles, and most of them armed with stiff sharp spines, set in little woolly cushions occupying the place of the buds. The flowers, produced near the apex of the plant, are generally large and showy, yellow and rose being the prevailing colours. They are succeeded by succulent fruits, which are exserted, and frequently scaly or spiny, in which respects this genus differs both from *Melocactus* and *Mammillaria*, which have the fruits immersed and smooth. One of the most interesting species is the *E. Visnaga*, of which some very large plants have been from time to time imported. A specimen weighing one ton, and measuring 9 feet high, and 3 feet in diameter, was received at Kew some years since, but owing to injuries received during transit, it did not long survive. These large plants have from forty to fifty ridges, on which the buds and clusters of spines are sunk at intervals, the aggregate number of the spines having been in some cases computed at upwards of 50,000 on a single plant. These spines are used by the Mexicans as toothpicks, whence the name Visnaga.

CEREUS.—This group bears the trivial name of Torch Thistle. It comprises about 150 species, scattered through South America and the West Indies. In one series, numbering between twenty and thirty species, sometimes separated under the name of *Echinocereus*, the stems are short, branched or simple, divided into few or many

ridges, all armed with sharp formidable spines; but in the greater number of species the stems are columnar or elongated, some of the latter creeping on the ground or climbing up the trunks of trees, rooting as they grow. One of the former group, *C. pectinatus*, produces a purplish fruit resembling a gooseberry, which is very good eating; and the fleshy part of the stem itself, which is called Cabeza del Viego by the Mexicans, is eaten by them as a vegetable after removing the spines. To the latter group belongs *C. giganteus*, the largest and most striking species of the genus, a native of hot arid desert regions of New Mexico, growing there in rocky valleys and on mountain sides, where the tall stems with their erect branches have the appearance of telegraph poles. The stems grow to a height of from 50 feet to 60 feet, and have a diameter of from 1 foot to 2 feet, often unbranched, but sometimes furnished with branches which grow out at right angles from the main stem, and then curve upwards and continue their growth parallel to it; these stems have from twelve to twenty ribs, on which at intervals of about an inch are the buds with their thick yellow cushions, from which issue five or six large and numerous smaller spines. The fruits of this plant, which are green oval bodies from 2 to 3 inches long, contain a crimson pulp from which the Pimos and Papagos Indians prepare an excellent preserve; and they also use the ripe fruit as an article of food, gathering it by means of a forked stick attached to a long pole. The Cereuses include some of our most interesting and beautiful hothouse plants.

PILOCEREUS, the Old Man Cactus, forms a small group with tallish erect fleshy angulate stems, on which, with the tufts of spines, are developed hair-like bodies, which, though rather coarse, bear some resemblance to the hoary locks of an aged man. The plants are nearly allied to *Cereus*, differing chiefly in the floriferous portion developing these longer and more attenuated hair-like spines, which surround the base of the flowers, and form a dense woolly head or cephalium. The most familiar species is *P. senilis*, a Mexican plant, which though seldom seen more than a foot or two in height in greenhouses, reaches from 20 feet to 30 feet in its native country.

ECHINOPSIS is another small group of species, separated by some authors from *Cereus*. They are dwarf, ribbed, globose, or cylindrical plants; and the flowers, which are produced from the side instead of the apex of the stem, are large, and in some cases very beautiful, being remarkable for the length of the tube, which is more or less covered with bristly hairs. There are about thirty species known, their geographical range extending from Mexico and Texas to Brazil, Bolivia, and Chili.

PHYLLOCACTUS, the Leaf Cactus family, consists of about a dozen species, found in Mexico and Brazil. They differ from all the forms already noticed in being shrubby and epiphytal in habit, and in having the branches compressed and dilated so as to resemble thick fleshy leaves, with a strong median axis, and terete woody base. The margins of these leaf-like branches are more or less crenately notched, the notches representing buds, as do the spine-clusters in the spiny genera; and from these crenatures the large showy flowers are produced. As garden plants the *Phyllocacti* are amongst the most ornamental of the whole family, being of easy culture, free blooming, and remarkably showy, the colour of the flowers ranging from rich crimson, through rose-pink, to creamy white. They are often called *Epiphyllum*, which name is, however, properly restricted to the group next to be mentioned.

EPIPHYLLUM.—This name is now restricted to two or three dwarf branching Brazilian epiphytal plants of extreme beauty, which agree with *Phyllocactus* in having the branches dilated into the form of fleshy leaves, but differ in having them divided into short truncate leaf-like portions, which are articulated, that is to say, provided with a joint by which they separate spontaneously; the margins are crenate or dentate, and the flowers, which are large and showy, magenta or crimson, appear at the apex of the terminal joints. In *E. truncatum* the flowers have a very different aspect from that of other *Cacteæ*, from the mouth of the tube being oblique and the segments all reflexed at the tip. The short separate pieces of which these plants are made up grow out of each other, so that the branches may be said to resemble leaves joined together endwise.

RHIPSALIS, a genus of about thirty tropical American species, contains some of the plants once referred to *Cactus*. It is a very heterogeneous group, being fleshy-stemmed with a woody axis, the branches being angular, winged, flattened, or cylindrical, and the flowers small, short-tubed, succeeded by small, round, pea-shaped berries. *Rhipsalis Cassytha*, when seen laden with its white berries, bears no inconsiderable resemblance to a branch of mistleto. All the species are epiphytal in habit.

OPUNTIA, the Prickly Pear, or Indian Fig Cactus, is a large typical group, comprising some 150 species, found in North America, the West Indies, and warmer parts of South America, extending as far as Chili. In aspect they are very distinct from any of the other groups. They are fleshy shrubs, with terete woody stems, and numerous succulent branches, composed in most of the species of separate joints or parts, which are much compressed, often elliptic or suborbicular, dotted over in spiral lines with small fleshy caducous leaves, in the axils of which are placed the areoles or tufts of glochidiate or hooked spines of two forms. The flowers are mostly yellow or reddish-yellow, and they are succeeded by pear-shaped or egg-shaped fruits, having a broad scar at the top, furnished on their soft fleshy rind with tufts of small spines. The sweet juicy fruits of *O. vulgaris* and *O. Tuna* are much eaten under the name of prickly pears, and are greatly esteemed for their cooling properties. Both these species are extensively cultivated for their fruit in Southern Europe, the Canaries, and Northern Africa; and the fruits are not unfrequently to be seen in Covent Garden Market and in the shops of the leading fruiterers of the metropolis.

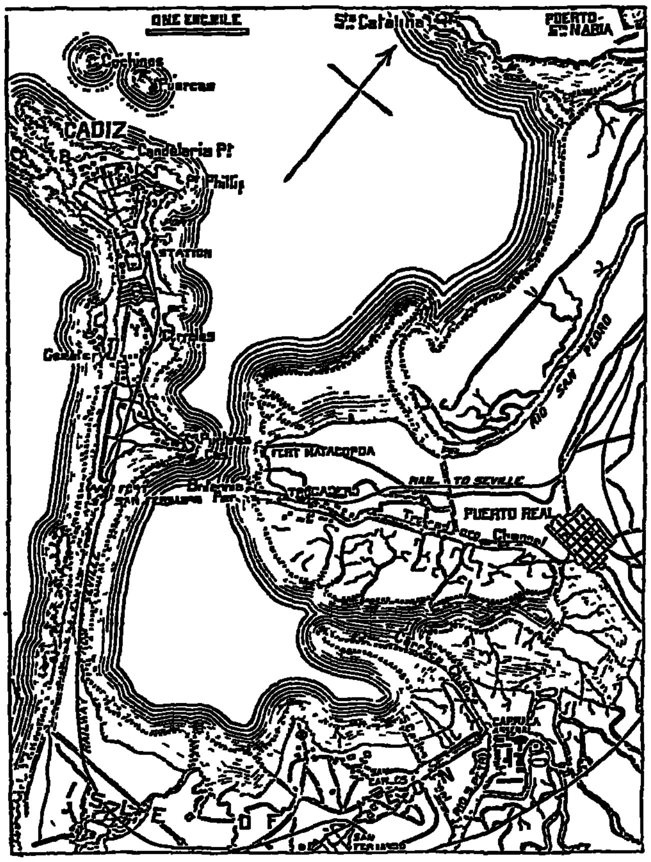
The cochineal insect is nurtured on a species of *Opuntia* (*O. coccinellifera*), separated by some authors under the name of *Nopalea*, and sometimes also on *O. Tuna*. Plantations of the nopal and the tuna, which are called nopaleries, are established for the purpose of rearing this insect, the *Coccus Cacti*, and these often contain as many as 50,000 plants. The females are placed on the plants about August, and in four months the first crop of cochineal is gathered, two more being produced in the course of the year. The native country of the insect is Mexico, and it is there more or less cultivated; but the greater part of our supply comes from New Granada and the Canary Islands.

PERESKIA ACULEATA, or Barbados Gooseberry, the *Cactus Pereskia* of Linnæus, is the only remaining generic type; and this differs from the rest in having woody stems and leaf-bearing branches, the leaves being somewhat fleshy, but otherwise of the ordinary laminate character. The flowers are subpaniculate, white or yellowish. This species is frequently used as a stock on which to graft other *Cacti*. There are about a dozen species known. (T. MO.)

CADAHALSO, JOSE DE (1741–1782), a Spanish poet and writer, was born at Cadiz in 1741. He was educated at Paris, and before completing his twentieth year had travelled through Italy, Germany, England, and Portugal, and had studied with care the languages and literatures of these countries. On his return to Spain he entered the army, and rose to the rank of colonel. He was killed at the siege of Gibraltar, 27th February 1782. His first published work was a tragedy after the French model, *Don Sancho Garcia*, printed in 1771. In the following year he published his *Eruditos á la Violeta* (Fashionable Learning), a satire on superficial knowledge, which was very successful. In 1773 appeared a volume of miscellaneous poems, and after his death there was found among his MSS. a series of fictitious letters, somewhat after the style of the *Lettres Persanes*, or the *Citizen of the World*, which were published as *Moorish Letters*, and have been frequently reprinted. The complete edition of his works, with life by Navarrete, appeared at Madrid, in 3 vols., 1818.

CADIZ (in Latin *Gades*, and formerly called *Cales* by the English), the capital of a province of the same name in Spain, is built on the extremity of a tongue of land projecting about five miles into the sea, in a direction N.W. from the Isla de Leon, in 36° 31′ N. lat., 6° 18′ W. long., 94 miles by rail south of Seville, and 13 from Xeres. The city, which is six or seven miles in circumference, is surrounded by a wall with five gates, one of which communicates with the isthmus. Seen from a distance off the coast, it presents a magnificent display of snow-white turrets rising majestically from the sea; and for the uniformity and elegance of its buildings, it must certainly be ranked as one of the finest cities of Spain, although, being hemmed in on all sides, its streets and squares are necessarily contracted. Every house in the city annually receives a coating of whitewash, which, when it is new, produces a disagreeable glare in the streets. The most characteristic feature of Cadiz is the marine promenades, fringing the city all round between the ramparts and the sea, especially that called the *Alameda* on the eastern side, commanding a view of the shipping in the bay and the ports on the opposite shore. The principal square is the Plaza de San Antonio, surrounded by handsome houses with elegant façades, the centre pleasantly shaded with trees, and furnished with numerous seats of marble. Communicating with it is the principal street (Calle Ancha), in which are the exchange and houses of the nobility. The houses are generally lofty

and well-built, with open central courts, surmounted by turrets and flat roofs in the Moorish style. The principal public buildings are the two cathedrals (one built in the 13th century, the other begun in 1720, but not completed till 1840); the Hospicio or Casa de Misericordia, adorned with a marble portico, and having an interior court with Doric colonnades; the bull-ring, with room for 12,000 spectators; the two theatres, the prison, the custom-house, and the lighthouse of San Sebastian on the western side, rising 172 feet from the rock on which it stands. Besides the Hospicio already mentioned, which sometimes contains 1000 inmates, there are numerous other charitable institutions, such as the women's hospital, the foundling institution, the admirable Hospicio de San Juan de Dios for men, and the lunatic asylum. Gratuitous instruction is



Plan of Cadiz and its environs.

given to a large number of children, and there are several mathematical and commercial academies, maintained by different commercial corporations, a nautical school, a school of design, a theological seminary, a flourishing medical school, an *Academia de Nobles Artes* (founded in 1789, principally by the exertions of Governor O'Reilly), an excellent observatory, and a hydrographic depôt. There are several public libraries attached to the various educational establishments, but none of any note. The museum is filled for the most part with wretched copies of ancient masterpieces, but in the church of the Capuchinos, which was formerly a monastery, is an unfinished picture of the marriage of St. Catherine by Murillo, the last effort of his pencil, as he met his death by falling from the scaffold on which he was painting.

Cadiz is the see of a bishop, who is suffragan to the archbishop of Seville, but its chief conventual and monastic institutions have been suppressed. Its noble bay, more than 30 miles in circuit and almost entirely land-locked by the isthmus and the headlands which lie to the N.E., has principally contributed to its commercial importance. The outer bay stretches from the promontory and town of Rota to the mouth of the Guadalete; and the inner bay, protected by the forts of Matagorda and Puntales, affords generally good anchorage, and contains a harbour formed by a projecting mole, where vessels of small burden may discharge. The entrance to the bays is rendered somewhat dangerous by the low shelving rocks (Cochinos and Las Puercas), which encumber the passage, and by the shifting banks of mud deposited by the Guadalete and the Rio Santi Petri. On the mainland, at the mouth of the latter river, is the village of Caracca, which contains about 6000 inhabitants, and possesses a naval arsenal and dockyard; and on the isthmus are situated the well-frequented sea-bathing establishments.

The commercial greatness of Cadiz is no longer what it was in the 17th and 18th centuries. At one time it was the great focus of intercourse between Spain and the Spanish colonies; and from 1720 to 1765 it enjoyed a monopoly of the traffic with Spanish America, which had previously been in the hands of Seville. Its prosperity began to decline when the trade of San Domingo, Cuba, Porto Rico, and the other islands was opened up to the greater ports of Spain, and decayed almost entirely in the beginning of the present century, when the colonies achieved their independence. An attempt was made by the Spanish Government in 1828 to restore its former greatness, by making it a free warehousing port, but this valuable privilege was withdrawn in 1832. Since the opening of the railway to Seville and the improvements effected in the harbour, the commercial activity has greatly increased; and in spite of the disturbing influences of political revolutions, Cadiz is still one of the most important ports in Spain. It is the European terminus of many of the principal mail-lines from the colonies both in the east and west. Besides the Xeres wine, for which it received in 1872 no less than £2,458,487 from Britain alone, it exports quicksilver, brandy, oil, provisions, flour, and wool. The salt trade, which was formerly of considerable extent, is almost extinct. The imports consist chiefly of sugar and coffee from Havana and Porto Rico, English coal from Cardiff, cocoa, hemp, flax, linens, dried fish, hides, cotton and woollen manufactures, rice, spices, indigo, staves, and timber. The total number of vessels that entered in 1872 was 1140, of which 494 were steamships; and the total tonnage was 287,850. Of the sailing vessels 179 were British and 136 Italian, of the steamships 127 British and 281 Spanish. The manufactures of Cadiz are unimportant, though a considerable stimulus to industry is given by the *Sociedad economica de Amigos del Pais*, which introduced the cochineal plant, and grants medals for improvements in manufactures.

Cadiz is strongly fortified with ramparts and bastions and defended by the forts of San Sebastian, Santa Catalina, Matagorda, and Puntales Castle. On the neighbouring coast the isthmus is protected by an intrenchment called the Córtadura, or Fort San Fernando.

From its almost insular position it enjoys a mild and serene climate, the mean annual temperature being about 64° Fahr., while the mean summer and winter temperatures vary only about 10° above and below this point. From the same cause it labours under a great deficiency of water, which must either be collected in cisterns from the tops of the houses or brought at great expense from Santa Maria on the opposite coast. Population in 1845, 53,922, and in 1860, 71,521.

Cadiz is identical with the ancient Agadir, Gadir, or Gaddir (in Greek *Gadeira*), which was a flourishing Phœnician colony long before the beginning of classical history, and continued in the hands of the Carthaginians, though somewhat disaffected to them,

till after the Punic wars, when Spain became a Roman province. C. Julius Cæsar conferred the *civitas* of Rome on all its citizens in 49 B.C.; and not long after L. Cornelius Balbus Minor built what was called the "New City," constructed the harbour which is now known as Puerto Real, and erected the bridge across the strait of Santi Petri, which unites the Isla de Leon with the mainland, and is now known as the Puente de Zuazo, after Juan Sanchez de Zuazo, who restored it in the 15th century. Under Augustus, when it was the residence of no fewer than 500 *equites*, it was made a municipium with the name of Augusta Urbs Gaditana, and its citizens ranked next to those of Rome. Some remains of the ancient city, and particularly of the temple of Hercules, are said to be visible below the sea. After the fall of Rome it was destroyed by the Goths, and remained in obscurity under the Moors, from whom it was retaken by Alphonso the Wise in 1262, but it emerged again when the discovery of America made it valuable as a market for colonial produce. In more recent contests Cadiz has been subjected to several disasters. It was taken and pillaged in 1596 by the British fleet, under Essex and Howard, in revenge for the Spanish Armada. It was attacked, but without success, by Lord Wimbledon in 1626, and by the duke of Ormond and Sir George Rooke in 1702. It was bombarded by Nelson in 1800. In 1808 the Spanish patriots in Cadiz brought the French fleet, which lay in the bay blockaded by Admiral Collingwood, to a surrender; and they were in turn subjected to a protracted siege of two years by Marshal Victor, from which they were relieved by the successes of Wellington in the Peninsula. It was once more reduced by the Duke d'Angoulême in 1823, and remained in the hands of the French till 1828. In 1868 the city was the centre of the revolution which effected the dethronement of Queen Isabella.

CADMIUM, a metal closely allied to zinc. It was discovered in 1817 by Stromeyer and Hermann, independently, but in a similar manner. The former chemist, in the execution of his duties as inspector of pharmaceutical products in Hanover, found a substance, sold as oxide, to be really carbonate of zinc, and, applying to the manufacturer for explanation of the reason of the substitution of the latter product for the former was informed that, although the best zinc, in which no iron could be detected, was employed, the oxide could not be produced without a slight discoloration from oxide of iron. On investigation by Stromeyer, it was found that the discoloration was due not to iron but to the oxide of a new metal, which he succeeded in isolating, and named cadmium, from the old chemical name for zinc oxide (*Cadmia fossilis*). About the same time, the sale of an oxide of zinc supplied by Hermann, a chemical manufacturer, who produced it from the waste of the Silesian zinc furnaces, was stopped in Prussia as being contaminated with arsenic,—the reason obviously being that the acid solution of the substance in question gave a bright yellow precipitate when heated with sulphuretted hydrogen. The erroneous character of this inference was, however, soon demonstrated by Hermann, who made a careful investigation of the subject, and discovered the nature of the new metal, but not before Stromeyer had published the results of his observations.

Cadmium does not occur in the metallic state in nature, and there is only one definite mineral known which contains it in quantity, namely, the sulphide, or greenockite, which occurs at Bishopstown, in Renfrewshire, in small isolated crystals of a bright orange-yellow colour, belonging to the hexagonal system, in a doleritic rock associated with prehnite. This contains 77·7 per cent. of cadmium and 22·3 per cent. of sulphur, corresponding to the formula CdS, and is isomorphous with voltzite, the rhombohedral form of sulphide of zinc. Although an extremely rare mineral in the pure state, being confined to the single locality mentioned above, sulphide of cadmium is often present in zinc blende, the richest varieties containing 3 per cent. of cadmium. Among these are the yellow radiated blende of Przibram in Bohemia, Eaton in New Hampshire, and Engis and Corfali in Belgium. It is also found in the carbonates and silicates of zinc from most of the localities producing these ores, but in what state of combination is doubtful, as it is not generally found in quantity sufficient to be appreciated by the analysis of samples,—being only discoverable when the ore is treated for zinc on the large scale, in the first products of the reducing processes.

Cadmium is a white metal with a slight bluish tinge by reflected light; it is whiter than lead or zinc, but less so than silver, has a high lustre when polished, and breaks, under a gradually increasing strain, with the fibrous or scaly fracture characteristic of a soft tough metal. It may be readily crystallized in octohedra, differing in this respect from the allied metal zinc which is rhombohedral. It is somewhat harder than tin, but less so than zinc, and like the former metal it emits a peculiar crackling sound when bent. It is malleable, and may be rolled into thin sheets. The specific gravity after fusion is 8·604, which is increased by hammering to 8·694. The specific heat is 0·05669 (Regnault), or 0·0576 (Dulong and Petit). The electric conductivity is 22·10, or somewhat lower than that of zinc; the thermal conductivity does not appear to have been determined. It melts at a temperature below redness (315° to 320° C.), and boils at the temperature of 860° C., giving off a vapour of an orange-yellow tint. The principal coloured lines with their relative intensity observed in the spectrum of cadmium vapour are, according to Huggins's notation, 502^{4}, 639^{1}, 656^{8}, $889^{6\cdot5}$, 918^{1}, 953^{1}, 986^{1}, 1473^{10}, 1517^{10}, 1536^{1}, 1747^{1}, 1843^{10}, 2315^{8}, 2562^{6}, 3239^{4}. The most brilliant of these are chiefly in the green and blue field.

Chemically cadmium belongs to the diatomic group of elements; its symbol is Cd, and its equivalent 58. It unites readily with most of the heavy metals, forming alloys, which with gold, copper, and platinum, are brittle, while those with lead and tin are malleable and ductile. The alloy of $\frac{2}{3}$ silver and $\frac{1}{3}$ cadmium is very tenacious; but that, in the reverse proportion, of $\frac{1}{3}$ silver and $\frac{2}{3}$ cadmium is brittle. An alloy of two parts of cadmium, two of lead, and four of tin, known as Wood's fusible metal, melts at a somewhat lower point than the similar alloy where bismuth takes the place of cadmium, or Darcet's fusible metal (see BISMUTH). It forms several amalgams, among which those containing equal parts of mercury and cadmium and two of mercury to one of cadmium are remarkable for their cohesive power and malleability; whereas that containing 22 per cent. of cadmium is hard and brittle. The amalgams of the former class have been proposed at different times for use in stopping teeth, but are not now so employed. When exposed to damp air cadmium becomes rapidly covered with a dull film of suboxide, but as with zinc the oxidation is only superficial, the crust formed protecting the metal below from further change. When heated to a redness in air it burns, forming a yellowish brown oxide. It also, when in a state of vapour, decomposes water at a red heat, with the formation of oxide of cadmium, hydrogen being evolved. It is soluble with evolution of hydrogen, in sulphuric, hydrochloric, nitric, and even acetic acid, forming colourless salts. When treated with an aqueous solution of sulphurous acid, it dissolves without evolution of hydrogen, sulphite and sulphide of cadmium being found in the liquid.

Oxide of cadmium, CdO, is a yellowish brown powder of the specific gravity 6·95, varying in depth of tint according to the temperature at which it is prepared. It may be produced by burning the metal in air or by calcining the nitrate or carbonate. It is readily reducible by hydrogen or carbon, at a high temperature, but below that necessary for the reduction of zinc oxide. If a mixture of the oxides of the two metals be heated in a current of hydrogen in a glass tube, the oxide of cadmium is reduced, volatilizes, and condenses in the cooler part of the tube, while the oxide of zinc remains unchanged. Oxide of cadmium is a strong base, forming salts similar in constitution to those formed by oxide of zinc, and those of the earthy and alkaline metals. The most important of these is the sulphate,

$CdSO_4$, which is produced when the metal or its oxide is dissolved in sulphuric acid, forming crystals containing either one or four atoms of water, the former being deposited from a boiling solution, and the latter at the ordinary temperature of the air. The uses of cadmium salts are very limited; the sulphate is employed to a small extent as a lotion in inflammation of the eyes, similarly to the sulphate of zinc, and the iodide in photography and in medicine for the same purposes as iodide of potassium. The only compound of any real importance is the sulphide, CdS, which produces several brilliant yellow and orange colours. These are quite permanent, unlike the yellow produced by lead, chromium, or other metals, which are all more or less subject to discoloration when exposed to the action of sulphuretted hydrogen in the atmosphere. It is produced when sulphuretted hydrogen, or an alkaline sulphide, is added to the solution of any cadmium salt, as an orange-red powder, which becomes carmine-red when heated. At a white heat it melts, and solidifies on cooling in lemon-yellow scales of a micaceous structure. When the precipitated sulphide is heated in hydrogen it is decomposed, forming cadmium vapour and sulphuretted hydrogen, which reunite in the cooler part of the tube, producing crystals exactly similar to the native mineral greenockite.

The best test for cadmium is afforded by the colour of the deposit formed on charcoal when it is volatilized and oxidized before the blowpipe flame. This is of a reddish brown colour, and usually shows the colours of thin plates from the tenuity of the film; whereas zinc under the same conditions gives a deposit which is bright yellow while hot, but becomes white on cooling. The precipitation as a yellow sulphide from an acid solution is another distinguishing character, as sulphide of zinc does not separate except from neutral or alkaline solutions. In quantitative analysis it is always estimated as oxide, being separated from solution as carbonate by precipitation with carbonate of sodium, which is converted into oxide by calcination. Cadmium, like lead, may also be separated from its solution in acids by means of zinc, which precipitates it in a dendritic form, like the well-known lead tree.

The production of cadmium is restricted to a very few localities. At Engis in Belgium it occurs in zinc blende to the extent of about 0·2 per cent. The oxide formed, together with oxide of zinc in the calcination of the blende, is in the subsequent reducing process in the ordinary Belgian zinc furnace (see ZINC), reduced and volatilized in the first period of the operation, before the heat is raised sufficiently to produce much zinc vapour, and the vapour, on coming in contact with the air, burns with a characteristic brown flame as distinguished from that of zinc, which is bluish green. The deposit formed in the condensing tubes, and in the nozzles (*allonges*) in front of the retorts, during this part of the process is comparatively rich in cadmium oxide, averaging about 1½ per cent. It is put aside until a sufficiency is collected, when it is enriched by a second distillation up to about 6 per cent., this second product being finally reduced by a third distillation with carbon at a dull red heat. The furnace contains fifteen retorts, four of which are reserved for the reduction of the enriched oxide. Cast-iron tubes are used, as the vapour of the metal readily penetrates clay retorts. The loss on the process is very considerable, only 30·12 per cent. of the whole amount of cadmium contained in the material treated being recovered; 21·17 per cent. is left in the residues, and 48·71 per cent. escapes condensation. The total produce of cadmium is very small; about one-half of the amount is produced at Engis, and the remainder in Silesia. In 1874 the production of cadmium in Lower Silesia amounted to 25 cwt., valued at £990 or about £800 per ton; but owing to the small demand many works had given up the manufacture. (H. B.)

CADMUS, in Greek Legend, was the founder of the town of Thebes originally called Cadmeia, and according to the tradition was a son of Agenor, king of Phœnicia, whence he had proceeded to Greece in search of his sister Europa, but failing to find her had, in obedience to an oracle, settled at Thebes. He there founded a town over which he in time became king, received from the gods Harmonia, a daughter of Ares and Aphrodite, as his wife, by her had a family on whom fell heavy misfortunes, and finally retired with her to Illyria, where they both died in peace, and were transformed into snakes which watched the tomb while their spirits were translated to Elysium. At the marriage all the gods were present, and the muses sang. Harmonia received a dress (*peplos*) worked by Athena, and a necklace made by Hephæstus. Their offspring were Semele, Ino, Autonoë, Agave, and a son Polydorus. On his first settlement at Thebes, Cadmus had slain a dragon, which guarded a spring, and at the orders of Athena had sown its teeth in the ground, from which there sprang a race of fierce armed men (Spartoi). By throwing a stone among them Cadmus caused them to fall upon each other till only five survived, and they became the founders of the noblest families of Thebes. Cadmus, however, because of this bloodshed, had to do penance for a long year (*i.e.*, eight years). Such is the legend. When Greek writers came to explain it they identified Cadmus as a Phœnician hero who had introduced into Greece the Phœnician writing, mining, and other arts or institutions of civilization. But his name is Greek rather than Phœnician, and like Cadmilus in Samothrace appears to mean "order," and to indicate a person who has instituted order in a state. He may have adopted much from the early Phœnician traders; but from the fact of Thebes having been one of the seats of the primitive Pelasgi, and from the occurrence of Cadmilus in Samothrace, also a seat of the Pelasgi, it is very probable that Cadmus was originally a purely Greek hero.

CADUCEUS (*κηρυκεῖον*), the symbol of office carried by public heralds, by Mercury (Hermes), as herald or messenger of the gods, and by Iris, Victory, and Eirene. It consisted of a staff round which two serpents were twined in a knot, their heads meeting at the top of the staff. Mercury, it was said, had seen two serpents fighting and knit together so, and had chosen this as a symbol of the quarrels which it was his duty to assist in settling. Sometimes a pair of wings are attached to the staff to indicate the speed of Mercury as a divine messenger. In the British Museum there is a bronze caduceus, found in a tomb in Sicily, which appears, from the inscription engraved on it in early Greek letters, to have belonged to a public herald of the town of Longena.

CÆDMON, or CEDMON (the former way of spelling is that of Bede, the latter that of Florence of Worcester), is the name of the earliest Anglo-Saxon or Old English poet of whom we have any knowledge. The meaning of the name has been much disputed. Sir Francis Palgrave, despairing of finding a native derivation, suggested (*Archæologia*, vol. xxiv.) that the poet might have been so called from the Chaldaic name for the book of Genesis, which is "b' Cadmin," in the beginning, or "Cadmon," beginning, from the opening words of the first chapter of Genesis. He thought that he might even have been an "Eastern visitor," who had arrived in Britain from the East, mastered the language, and come out as a vernacular poet. A hypothesis so fanciful as this last may be at once rejected. Another suggestion of the same lively writer connects the name with the Adam Cadmon (the primitive and ideal man) of the Cabalists. It is true that Cabalistic speculations cannot be traced back with certainty beyond the 9th century, but it is quite possible that the word may have

been recognized as an important word in the East, and as bearing a distinct philosophic or theosophic meaning at a far earlier date. On the other hand, in favour of the view which gives to the name a native origin, it may be urged that Bede, though he only employs the word once, says in that passage that the poet's nocturnal visitant "called him by his name," and said, "Cædmon, &c." Does not this look as if the name had a homely and north-country sound in Bede's ears? If so, What did it mean? Sir Francis Palgrave maintains that no Anglo-Saxon derivation can be found for the first part of the name. Dr Bouterwek, however (in a work on Cædmon, published at Elberfeld in 1845), together with Professor Sandras, explains *ced* as meaning a boat in Anglo-Saxon, whence the former translates the name "pirate," the latter "boat-man." This would be satisfactory if it rested on any ground of fact; but unfortunately this word "ced" is a pure invention of Professor Bouterwek's; neither the Anglo-Saxon language, as known to us, nor the Old English of the first three centuries after the Conquest, nor any local dialect contains any such word. On the whole, Sir Francis Palgrave's first suggestion seems to involve the least difficulty. "Cadmon" means "beginning" in the Targum of Onkelos, the Chaldee version of the Scriptures, which was in popular use among the Jews from the 1st century B.C. downwards, and some learned ecclesiastic at Whitby who had visited the Holy Land may have given to the poet the name Cadmon (which in Anglo-Saxon mouths became Cædmon), because he was to sing of the "beginning" of things.

The few particulars that are known of the life of Cædmon are all to be found in Bede's *Ecclesiastical History*, a book so well known that an abridgement of them is all that will be necessary here. Cædmon was probably a ceorl, employed under the "villicus" or bailiff of the lands belonging to the monastery of St Hilda at Whitby. He had arrived at mature age, and had embraced Christianity at the call of the devoted Irishmen who from Iona and from Lindisfarne, through two-thirds of the 7th century, spread the light of faith through the regions of northern England. He used to attend festive meetings; but when the song went round, and the harp was passed into his hands, Cædmon, ignorant of the rough old battle-songs of the heathen time, could sing nothing. On one such occasion he is said to have left the feast and gone to the stables, where it was his turn that night to attend to the horses and plough-oxen. He fell asleep, and dreamed that a person appeared to him, who, calling him by his name, said, "Cædmon, sing me something." On his replying that he could not sing, and that on this account he had left the revellers, the other replied, "Nevertheless thou shalt sing for me." "What," said Cædmon, "must I sing?" "Sing," he answered, "of the beginning of created beings" (*principium creaturarum*). Thereupon Cædmon began to sing verses which he had never heard or learned, praising and magnifying the Creator who had made heaven and earth for the children of men. Awaking from his sleep he remembered the verses which had come to him in his dream, and added others to them.

In the morning he went to the bailiff who was over him and told him what had happened; the bailiff took him to the abbess. St Hilda assembled a company of pious and learned persons, and before them trial was made of Cædmon's gift. He told his story, and repeated the verses, and they all judged that he had received an inspiration from above. They explained to him then and there a passage from holy writ, and desired him to versify it. He went away and returned the next morning with his task most excellently performed. The abbess then received him "*cum omnibus suis*" (it is not easy to determine whether this phrase applies to his kith and kin or merely to his worldly goods) into the monastery; and there he lived as a monk for the remainder of his life, employing diligently his leisure hours in the cultivation of the gift which he had received. The English poets who, up to the time when Bede wrote, had attempted to write religious poems in imitation of Cædmon, had, in the historian's opinion, fallen far short of him. How long he lived in the monastery we are not informed. The narrative of his death, beautiful in its piety and simplicity, relates how, after an illness of fourteen days, he desired to be removed to the infirmary, where, on the same night, after receiving the Eucharist by way of viaticum, and "signing himself with the sign of the holy cross," he sank into a peaceful slumber from which he never woke.

Florence of Worcester speaks of him, under the year 680, as that celebrated monk of St Hilda's Abbey who had received from heaven the free gift of poetic inspiration. William of Malmesbury, in the *Gesta Pontificum* (lib. iii. § 116), says that his relics had been discovered at Whitby shortly before he wrote (early in the 12th century), and had been, according to popular report, the occasion of miracles.

An important question remains— whether Cædmon was really the author of the metrical paraphrase of Genesis, Exodus, part of the book of Daniel, &c., which usually goes by his name. The unique MS. containing this paraphrase came into the hands of Archbishop Usher in the 17th century, and was by him given to the French scholar, Francis Dujon, better known as "Junius," who bequeathed it to the Bodleian Library It is in a hand of the latter part of the 10th century, and contains no indication of authorship. The poem opens as follows:—

Us is riht micel thæt we rodera weard,
Wereda wuldor-cining, wordum herigen,—

(For us it is very right that we should praise with our words the Guardian of the heavens, the glorious King of hosts.) A number of very curious illustrations, etchings heightened with green and red colour, are in the earlier portion of the MS.; engravings of them may be seen in the 24th volume of the *Archæologia*. Obviously the only means of identifying this anonymous poem as the work of Cædmon is to compare it, as to its opening and contents, with the poem described by Bede. The substance of Cædmon's opening, according to Bede, was this: "Now we ought to praise the author of the heavenly kingdom, the power of the Creator and His counsel, the deeds of the Father of glory. How He, since He is eternal God, is the author of all wonders, who, the Almighty Guardian of the human race, first created for the sons of men the heaven to be the roof of their abode, and afterwards the earth." The opening of the paraphrase, though more diffuse, agrees with that here described pretty well as to its general meaning, except that the heavens are represented in it as created for the angels rather than for the children of men, who do not come upon the scene till later. Were there no other evidence, it might seem not unreasonable to identify the paraphase with the poem of Cædmon. But here a new difficulty meets us. King Alfred translated Bede's *Ecclesiastical History*, and when he comes to this passage he gives us a metrical version of Bede's Latin description of the opening, which he seems to intend his hearers to take for the *ipsissima verba* of Cædmon. Of this there are two indications:—first, he renders Bede's words, "quorum [sc. versuum] iste est *sensus*," into "thara endebyrdnes this is," "their *order* is this;" secondly, he *omits* a long sentence immediately following the description of the opening, in which Bede explains that from the difficulty of translating verses literally from one language into another he has merely given the *sense* and not the "ordo ipse verborum." Now Alfred tells us that he *does* give the order (endebyrdnes) of the words and he leaves untranslated the passage which

affirms that only the general sense is given The verses which he inserts begin thus:—

> Nu we sceolon herian heofon-rices weard,
> Metodes mihte and his mod-gethonc,—

(Now must we praise the Warder of the heavenly kingdom, the might of the Creator, and the thought of His mind.) In short, Bede's description is turned with great literalness into Anglo-Saxon verses. But are these Cædmon's? If they are, then the paraphrase is not the work of Cædmon; for not one line in the opening as given by Alfred agrees with the paraphrast's opening However, in spite of the circumstances mentioned above, the judgment of criticism will not identify Alfred's verses with the true work of Cædmon. They are so bald, so literal, that the conviction forces itself upon us that Alfred is here merely translating from Bede's Latin, and amusing himself with making his version metrical On the other hand the paraphrast is a genuine poet; variety, force, and colour are the ever-present attributes of his poetic diction; his imagination is bold and fertile; his moral purpose clear and pervading—in fact he is just such a man as we should conceive the real Cædmon to have been.

The other point of comparison between the paraphrase and Bede's description relates to the *contents* of Cædmon's poem. "He sang," says the historian, "the creation of the world, the origin of man, and all the history of Genesis; and made many verses on the departure of the children of Israel out of Egypt, and their entering into the land of promise, with many other histories from holy writ; the incarnation, passion, resurrection of our Lord, and His ascension into heaven; the coming of the Holy Ghost, and the preaching of the apostles; also the terror of future judgment, the horror of the pains of hell. and the delights of heaven." With this account the contents of the paraphrase which we have agree, up to a certain point, remarkably well. It may be said, generally. to embrace the whole history of Genesis, except that portion which relates to events posterior to the time of Isaac. It then passes to the history of Moses and his statutes, "Moyses dómas," briefly giving the thread of events till it arrives at the passage through the Red Sea, on which the writer enlarges with evident enjoyment. An abrupt transition is then made to the book of Daniel; the story of the three children saved out of the fiery furnace is told; Daniel's dream-wisdom is set forth, and the doom denounced against Belshazzar. Then what is called the second book of the paraphrase, the beginning of which coincides with a change of handwriting in the MS., commences, and now the resemblance to Bede's description ceases. This book opens with the complaints of the fallen angels in hell and the lamentations of the souls detained in the *Limbus Patrum;* the descent of Christ after his passion to liberate these souls is described; the resurrection is barely mentioned, but the intercourse of Christ with his apostles previous to his ascension, and the ascension itself, are told at some length. The book concludes with a description of the terrors of the Day of Judgment. Such a poem cannot be said to correspond with Bede's description; but then it must be remembered that, partly on account of the change of hand and of subject, partly on account of the presence in it of later linguistic forms, the ascription of this second book of the paraphrase to the author of the first has always been held problematical. On the whole, although the grounds of a confident judgment do not exist, the analysis of the evidence here attempted points to the conclusion that the first book of the paraphrase, though not the second, may with considerable probability be assigned to Cædmon.

Some writers have assigned other extant poems to Cædmon, *e.g.*, the *Halga Rôd* (Holy Rood) of the Vercelli codex, a passage in which has been found to tally with the Runic inscription on the Ruthwell Cross, and also the fragment called *Judith*, in the MS. volume containing *Beowulf*. But the evidence in favour of either supposition may be set down as *nil;* nor does the style in *Judith*, still less in the *Halga Rod*, agree with that of the Paraphrast. (T. A.)

CAEN, or, as it is called in the old chronicles, CADON, CATHIM, CAHEM, or CAAM, the capital of an arrondissement in the department of Calvados in France. It stands about 80 or 90 feet above the level of the sea, in an extensive valley, on the left bank of the Orne, at the influx of the Odon, 9 miles from the English Channel, and 122 west of Paris, in 49° 11′ 14″ N. lat., 0° 21′ 15″ W. long. The town is handsome and well built; the streets, of which the most important is the Rue St Jean, are generally wide, straight, and clean; and the houses, being of freestone, have a very good appearance. Hardly any remains of its once extensive ramparts and towers are now to be seen; but the castle, founded by William the Conqueror and completed by Henry I., is still employed as barracks, though in a greatly altered condition. The city contains several ancient churches and other buildings, affording fine specimens of the Norman style of architecture. Among these are the church of St Pierre, dating from the 14th century and surmounted by a handsome stone spire, the finest in Normandy, 242 feet in height; the magnificent churches of the Abbaye Aux Hommes, or St Etienne, and the Abbaye Aux Dames, or Trinity, both founded in 1066,—the former by William the Conqueror, where a plain grey marble slab in the pavement now marks his long since desecrated tomb, and the latter by his queen Matilda, who was interred there. The old convent of the Capuchins is now occupied by the society of Le Bon Sauveur, which, founded by two poor girls about 1730, has grown into a most important institution, and maintains an asylum for the insane of both sexes, a charitable dispensary, a school for the education and industrial training of deaf and dumb children, and various minor establishments. Caen is the seat of a high court of appeal for the departments of Calvados, Manche, and Orne, and has tribunals of primary instance and commerce, a chamber of commerce, a *conseil de prud'hommes*, a university (founded in 1431 by Henry VI. of England), a royal college, a school of hydrography, a public library of 45,000 volumes. an extensive botanic garden, a museum belonging to the society of Norman antiquaries, and a theatre. There is a local *Académie des sciences, arts, et belles-lettres*, which has published a series of *Mémoires* since 1754. The commerce of Caen is considerable. It exports barley, flour, potatoes, wine, brandy, fruit, cattle, hardware; and imports timber from Norway, coal, pig-iron, oats, wheat, and oil-seeds. Its manufactures are of comparatively small importance with the exception of rape and colza oil, though there is a certain turn-out of caps, table-linen, cotton fabrics, leather, earthenware, and cutlery; breweries, dye-works, and ship-building yards are also in operation. The manufacture of lace, formerly of great extent, has very much declined. A fine kind of oolitic stone, in great favour as a building material, is quarried in the neighbourhood. Several large fairs are held annually. At high water, vessels of 150 or 160 tons can come up to the harbour, which consists of a part of the river bed and a basin 1896 feet in length by 164 in breadth, and has communication with the sea not only by the river, but also by a canal debouching at Ouistreham. A canal to connect it with the sea is in course of construction, which will render it accessible to large vessels. The town is situated on the main line of railway from Paris to Cherbourg, and is connected by branch lines with Courseulles on the coast, and with Laval inland.

Though Caen is not a town of great antiquity, the date of its foundation is unknown. It existed as early as

the 9th century, and when, in 912, Neustria was ceded to the Normans by Charles the Simple, it was a large and important city. Under the dukes of Normandy, and particularly under William the Conqueror, it rapidly increased. It became the capital of Lower Normandy, and in 1346 was besieged and taken by Edward III. of England. It was again taken by the English in 1417, and was retained by them till 1459, when it capitulated to the French, in whose possession it has since continued. In 1793 the city was the focus of the Girondist movement against the Convention. Among the numerous celebrities to whom Caen has given birth may be mentioned Malherbe, Boisrobert, Huet bishop of Avranches, and Tannegui Lefebvre. Population in 1872, 39,415 in the city, and 41,210 in the commune.

See L'Abbé de la Rue, *Essais historiques sur la ville de Caen*, 1820–42; Mancel, *Histoire de la ville de Caen*, 1844; Vauthier, ditto, 1843; L'Abbé Daniel, *Embellissements de la ville de Caen*, 1842; Freeman's *Norman Conquest*, vol. iii.; Macquoid's *Normandy*, 1874.

CÆRE (Καῖρε), called by the Greeks *Agylla* (Ἄγυλλα), which is probably an Etruscan name, a city of Southern Etruria, near the coast of the Tyrrhenian Sea. Its site is occupied by the modern Cervetri (*Cære vetus*), situated in the district of Civita Vecchia, about 32 miles from Rome. In the Virgilian legend of Æneas, Cære appears as the seat of the Etruscan king Mezentius; but the earliest fact in its genuine annals is its participation in an attack on the city of Alalia in Corsica. It afforded a refuge to the Tarquins on their expulsion from Rome, and it was afterwards chosen by the Romans as the securest hiding-place of their treasures during the Gallic occupation of their city. In the time of Strabo the city had become of little importance, and was even outgrown by the neighbouring village of *Aquæ Cæretanæ* It continued, however, to rank as a municipium, and in the 4th century of the Christian era had a "bishop" of its own; but in 1250 it was deserted by a large part of its inhabitants, who removed to what is now the village of *Ceri*. The chief building of modern date in Cervetri is the castle of the Ruspoli family, who are in possession of the seigniory From the inhabitants being admitted to the privilege of Roman citizenship, but without the right of suffrage, the "Cærite franchise" came to be a proverbial expression denoting disfranchisement. A large number of interesting Etruscan remains have been found in the tombs of Cære, among which may be specially mentioned paintings of high antiquity and inscriptions showing one of the sepulchres to have belonged to the Tarquin or Tarchnas family.

J. Hare, *Days near Rome*, 1875, vol. iii.; *Journal des Savants*, 43, &c.; and various articles in the *Annali* and *Bulletino dell' Inst. di Corrisp. Archeol. di Roma*, especially 1869, 1873, and 1874.

CAERLEON, the *Isca Silurum* of the Romans, is situated upon the right bank of the river Usk, about $3\frac{1}{2}$ miles N. of Newport in Monmouthshire. Its name appears to be a corruption of the Latin *Castrum Legionis*,[1] and there can be no doubt that the place was the station of the second Augustan legion and ranked as a colony and capital of Britannia Secunda in the period of Roman dominion. The existing remains of ancient Caerleon still *in situ* are unimportant, consisting only of fragments of the city walls and a grass-grown amphitheatre (comprising an area of 222 feet by 192 feet), in which the tiers of seats are indistinctly visible. The hamlet on the opposite bank of the river preserves its Roman name of *Ultra Pontem*, and it is probable that the connecting bridge was a pontoon similar in character to that which survived to the close of the last century. The local museum is rich in objects of interest, collected (chiefly through the zeal of Mr J. E. Lee, the author of *Isca Silurum*), either in Caerleon or its immediate neighbourhood. It includes a tesselated pavement of much beauty brought from Caerwent, four Tuscan pillars which are thought to have supported a temple of Diana, a large number of inscribed and sepulchral stones, a series of coins from the time of Otho to that of Honorius, stone coffins, *amphoræ*, *antefixa*, amulets, enamels, and Samian ware of home and foreign manufacture. It is remarkable that on two inscriptions the name of Geta (the younger son of Severus) has been mutilated and partially effaced—evidence of the hatred in which the civil governor was held by his brother Caracalla. In the recent restoration of the Parish church (in style Early English, with traces of rude Norman) a good deal of Roman masonry was brought to light, and upon the hill side, which formed the burial place of the ancient city, fragments of urns and memorial slabs are even now often exhumed. Enough has been discovered to prove that Caerleon was a place of great importance in Roman times, but not enough to support the hyperbolical language of Giraldus Cambrensis (borrowed from Geoffrey of Monmouth) that its "splendid palaces, with their gilded roofs, once emulated the grandeur of Rome" (bk. ix. c. 12).

Although the chief historic interest attaching to Caerleon is derived from the impress left upon it by Roman occupation, it has also a less substantial claim to notice in connection with the romance of Arthur and the Round Table. It was hither the "blameless king" came at Pentecost to be crowned, and made high festival with the chieftains from Lothian and Orkney, from Gower and Carados. Here, too, if we follow the laureate's version, Arthur took counsel with "Dubric, the high saint" and Guinevere climbed—

> "The giant tower, from whose high crest, they say,
> Men saw the goodly hills of Somerset,
> And white sails flying on the yellow sea.
> (*Idylls of the King, Enid.*)

The lofty mound upon which this tower is said to have stood is close to the Roman amphitheatre, to which the name of Arthur's Round Table has been given. The tumulus is evidently artificial, and may perhaps have supported the keep of the castle mentioned in *Domesday*, the ruins of which, now limited to a solitary bastion on the river side, were very extensive even in Leland's time.

The grantee of Caerleon at the Norman Conquest was William de Scohies, and the lordship was subsequently enjoyed by the Crown and the great families of Clare and Mortimer. From the latter it devolved to King Edward IV., and in later times has been held by the Morgans of Llantarnam and the Howes, Lords Chedworth. The chief proprietor at the present time is Sir Digby Mackworth, Bart.

The ecclesiastical history of Caerleon reaches back to the first introduction of Christianity into Britain, when it was constituted the seat of an archbishopric. It sent a representative to the councils of Sardis (347 A.D.) and Rimini (359); and in the persecution of Diocletian during the previous century two of its citizens, Aaron and Julius, are said to have suffered martyrdom. The see was transferred to St David's in the 11th century, and at the present time Caerleon is included within the diocese of Llandaff. Some remains of a Cistercian priory may still be traced, but even the memory of Dubricius, the stout opponent of the Pelagian heresy, has perished with his dwelling-place. (C. J. R.)

CAERNARVON. See CARNARVON.

[1] Nennius, writing about two centuries before Geoffrey of Monmouth, says (c. 56), "Bellum gestum ... Leogis, quæ Britannice Cair Lion dicitur."

CÆSALPINUS, Andreas (1519–1603), one of the most distinguished of the Italian natural philosophers of the Renaissance, was born at Arezzo in Tuscany in 1519. Of his family nothing is recorded, nor does he appear to have left any progeny, or to have been married.

We have no account of his life till we find him seated in the botanical chair of the university of Pisa, where also he studied, if he did not teach, anatomy and medicine. His first publication was entitled *Speculum Artis Medicæ Hippocraticum*, in which it were too much to expect he should have released himself from the shackles of his venerable guide; but he has left evident proofs, in a passage often quoted, of his having a clear idea of the circulation of the blood, at least through the lungs. In botany his inquiries were conducted on a more original plan, and their result was one of the most philosophical works in that science, issued from the press at Florence in 1583, in one volume quarto. The title-page is sufficiently arrogant in tone.—*De Plantis libri XVI. Andreæ Cæsalpini Aretini, Medici clarissimi doctissimique, atque Philosophi celeberrimi ac subtilissimi;* yet Cæsalpinus appears to have been the editor, and prefixed, in his own name, an elegant and learned epistle dedicatory to Francis de' Medici, grand duke of Tuscany. This book, now rarely to be met with, is not only the unacknowledged source from which various subsequent writers, and especially Morison, derived their ideas of botanical arrangement, but it was a mine of science to which Linnæus himself gratefully avowed his obligations. Linnæus's copy of the book evinces the great assiduity with which he studied it; he has laboured throughout to remedy the defect of which Haller complains of the want of synonyms, has subjoined his own generic names to nearly every species, and has particularly indicated those remarkable passages, at pages 13 and 15, where the germination of plants and their sexual distinctions are explained. In the former we trace the first rudiments of a natural classification of plants by the differences in their cotyledons, or, in other words, we find the origin of the natural systems of Linnæus and Jussieu; in the latter passage we detect the fundamental principle of the Linnean artificial system. Nor were these merely incidental suggestions of the author. He pursued his inquiries to a conclusion on which the existence of botany as a science depends, and which the no less eminent Conrad Gesner detected about the same time, though his ideas respecting it were not then made public. The principle to which we allude is the classification of plants by their parts of fructification alone. This was afterwards extended, by the greatest writers on the subject, as Ray and Tournefort, and more completely by Linnæus, to the discrimination of their genera by the same parts, more particularly considered and contrasted. To this more extensive conclusion, indeed, the principle directly and inevitably leads. Cæsalpinus used it himself with such success as to develop some of the most important characters for generic distinctions, such as the flower being superior or inferior with respect to the fruit; the heart of the seed situated at its summit or base; the seeds, or the cells of the seed-vessels, solitary or otherwise; the partitions of certain pericarps parallel or contrary to their valves. Linnæus remarks that Cæsalpinus, though the first systematical botanist, found out as many natural classes, or orders, as his followers. He did not indeed define well the philosophical limits of genera in the vegetable kingdom, and therefore his work cannot be regularly quoted throughout for generic synonyms. The want of plates of his own, and of references to other authors, renders, as we have already hinted, some of his names and descriptions unintelligible. Yet Linnæus has in manuscript filled up many blanks which he had been obliged to leave in his own *Classes Plantarum*, where the system of Cæsalpinus first assumed a synoptical form. The latter might probably have adopted a more clear and methodical mode of arranging and explaining the botanical part of his subject, had he not had in view the vague and desultory manner of Pliny, whom he closely imitates in the materials of his numerous chapters, as well as in his style of description. A small and unimportant *Appendix* to this work, of nineteen pages, appeared at Rome in 1603, which is of very rare occurrence, but may be found reprinted in Boccone's *Museo di Piante Rare*, p. 125. The *herbarium* of over 760 plants which he left is said to be still preserved at Florence.

Cæsalpinus having been settled at Pisa when the great Galileo first presumed to doubt the infallibility of the Aristotelian philosophy, and, most likely, at the time when that rising philosopher became professor of mathematics in the same university, we can hardly imagine him to have been free from the party-spirit which so disgracefully manifested itself there. He seems to have retained his professorship till 1592, when he removed to Rome in attendance on Pope Clement VIII. He died in 1603 at the age of eighty-four.

Cæsalpinus printed at Rome, in 1596, a quarto volume of above two hundred pages, entitled *De Metallicis*, dedicated to Pope Clement VIII. which, like his botanical publications, is now extremely rare. In the philosophy of this work Aristotle is his guide; in its method and composition, Pliny. A prefatory address to the pope declares it to have been undertaken in opposition to a certain treatise on the same subject, which, though written with diligence and elegance, contained many things inconsistent with the principles of philosophy, and subversive of the Peripatetic doctrines, and with the author of which, as being excommunicated by the holy church of Rome, no measures were to be kept.

The *Quæstionum Peripateticarum libri quinque*, published at Rome in 1603, diverge considerably from the pure doctrine of Aristotle, and by the emphasis laid on the universal and common intelligence inherent in matter, approximate rather to the pantheism of the Stoics.

CÆSAR, Caius Julius, was born July 12, 100 B.C., according to others in 102 B.C., of a family who for many years had held high offices in the state. He was the greatest man of the Roman or perhaps of all the ancient world. It is not without reason that his name has remained among us as the title of sovereignty, or that his memory survives as the standard of commanding greatness; yet the very completeness of his character makes it difficult to obtain a clear grasp of his individuality. In every relation of life he attained apparently without effort to the highest excellence, as a citizen, a politician, an orator, a general, a companion, a man of letters, and a far-seeing organizing statesman. Yet study will make it clear to us that his greatness has not been overrated, and the more we contemplate his position and his work, the less opportunity we shall find for blame or criticism. He entered into active life at a great crisis of his country's history. A strong national individuality, firmness and unity of character and purpose had gradually won for Rome the supremacy of Latium, of Italy, and of the world. But the qualities which were able to acquire an empire were not able to govern it. The time was now passed when the senate presented an example of dignity and magnanimity, when a sense of law and justice and persistency of aim and object sufficed to extenuate a cruelty which knew no limit but the realization of its will. It was truer now than in the time of Horace that Rome was falling by the weight of its own greatness. The long struggle between the patricians and plebeians for political equality served rather to strengthen than loosen the cohesion of the state. But the nations which lay outside the city could not be assimilated without severe struggles. The equality of Latins and Italians with the citizens of Rome might be

won by the efforts of a demagogue, but could only be assured by an entire change of government. Failure to effect the purposes of government had diminished the sense of responsibility in the ruling class. Jugurtha had been able to discover that Roman virtue was accessible to bribes. The direction of provinces at once gratified and stimulated the avarice of statesmen. The riches of the world which were beginning to flow into the imperial city excited the desire for more. There existed at the same time the demoralization which accompanies the breaking up and abandonment of old principles of conduct, and an unsettled yearning for the adjustment of pressing difficulties. We may credit the Gracchi with a far-seeing grasp of the wants of their country, but they could not but appear to their contemporaries as mischievous revolutionists. Sulla attempted to give new strength and power to a system which had sunk into hopeless decay. Marius was inspired rather with a rough contempt for expedients which could never be successful, than with a patriotic desire to elevate the people from whom he sprung. The impotence of statesmen to understand or to regulate the age led to the employment of violence and bloodshed. A domestic enemy had forced the gates of Rome, and each political victory was sealed with the blood of the vanquished. The senate which had conquered the world was unable to defend itself; it could neither recover its former power nor bring into being a new constitution. It could not exercise the ordinary functions of government without entrusting to a citizen powers which might be turned against its own existence. It is difficult to imagine what would have been the destiny of a world from which the cohesive force which bound it together might at any time be removed. If Rome had perished in this crisis she would have left but a faint impress upon the nations who owned her sovereignty. The long reign of law and order, from which we derive the chief legacies which Rome has left to the modern world, was yet to come. That the newly-founded empire did not fall before the onslaught of an eastern despot, or break up into separate provinces governed by rebellious citizens, is due, as far as we can see, to Julius Cæsar alone. It is difficult to see how such a man could have been produced by the wants of any age, but there is no doubt that the course of future history was marked out in no slight degree by the genius and foresight of this single individual.

Cæsar displayed at the very outset of his career the same versatility, energy, and courage which distinguished him till its close. When ordered by Sulla to put away his wife, who was connected with the Marian party, he refused to obey, although he lost by the refusal his wife's dower, his priesthood, and his fortune. Although compelled to quit Rome to avoid the dictator's anger, he did not deprive his country of his services. His diplomacy served to obtain from Nicomedes, king of Bithynia, a fleet, which was used in the reduction of Mitylene, and by his personal bravery in the siege he won from Marcus Thermus the reward of a civic crown. He served in Cilicia against the pirates, whose extinction was to be the great glory of his rival, and either at this or at a later time (for authorities differ on this point) had an adventure with them, which displays his subtlety and resource. Taken prisoner by them at the island of Pharmacussa he sent the main body of his companions and attendants to seek his ransom. During his stay of forty days, he ingratiated himself with his captors, and promised them in jest that when once set free he would return and crucify them, and he kept his word. When he was released he armed some vessels of Miletus, found the pirates in the anchorage where he had left them, took them into Pergamus, and handed them over to the civil arm. When a student under Apollonius Molo at Rhodes, on the outbreak of the Mithridatic war, he passed, of his own accord, to the continent, drove the king's general from the province, and restored the shaken allegiance of the subject towns. A Roman citizen of birth was expected not only to be a general and a statesman but an orator. He must be practised in every branch of the art of government. Cæsar attained distinction in the forum with the same ease as he had won it in the field. He accused Dolabella of extortion in the provinces in 77 B.C., and Antonius of a similar offence in 76 B.C. In neither prosecution was he successful, but he gained in both a reputation for eloquence and public spirit. To perfect himself in oratory he sought the instruction of Apollonius before mentioned, under whom Cicero had also studied, and who had striven with little success to curb the extravagance of his redundant diction. Perhaps it is to him that we owe the massive and monumental eloquence, the pure and chastened taste of the *Commentaries*. The chronology of these events is uncertain, but in 74 B.C. Cæsar returned to Rome, and was elected pontiff and military tribune. Not untried in war and in affairs, tinged with Greek culture but not weakened by it, in the prime of youth and the fulness of fascination, he was fitted in every way to gain the favour of his countrymen, and to play his part in the game of politics, which required then, if ever, an open brow and secret thoughts.

For the next twelve years Cæsar, with the exception of a short absence in Spain as quæstor, remained at Rome. During the whole of this time he lent his assistance to the task of strengthening and reviving the democratic party, which had sunk very low after the death of Marius. He was thus brought constantly into connection with Pompeius, and it is difficult for us to determine whether Cæsar supported Pompeius because he perceived that his ends were those which he himself wished to gain, or whether Pompeius courted the democratic party for the purpose of his own aggrandizement. In 70 B.C. Pompeius, in conjunction with Crassus, repealed the Sullan constitution, and in the measures which were necessary for this purpose he had the full approval and support of Cæsar. The power of the tribunes was restored, that of the senate diminished. The control of the law courts, which Sulla had given back to the senate, and which had been abused to shield from punishment high-born plunderers of the provinces, was now divided among the senate, the equites, who were the great capitalists, and the tribuni ærarii, who represented a still more popular element. Cæsar in this conduct was true to the principles which animated his whole career, a desire to give equality to the citizens, and recognition to the subjects of Rome, and to obliterate as far as possible the scars of civil dissension. In 68 B.C. he lost his aunt and his wife, one the widow of Marius, the other the daughter of Cinna. In the orations which he pronounced over them in the forum, he was able to rehabilitate the reputation of the leaders of his party. At his aunt's funeral he caused busts of Marius to be carried in the procession, and the people were roused to recall at once the greatness of their general, whose memory had been so long proscribed, and the generous courage of his kinsman in restoring it. As the power of the senate became weakened, respect for the old safeguards of the constitution became less strong. It was therefore not unnatural, when Rome was suffering from the attacks of enemies whom she could not quell, that she should invest her former general with an extraordinary command, and seek in new expedients a remedy which the constitution had failed to supply. Such was the origin of the Gabinian and Manilian laws, the first of which conferred on Pompeius a command against the pirates of the Mediterranean, while the second gave him control of the Mithridatic war. Never had such power been concentrated in the hands of a single citizen. He was invested with absolute control for three years over the whole

of the Mediterranean Sea, from the Straits of Gibraltar to the innermost bays of the Levant, and over the coasts for fifty miles inland. Under him were twenty-five prætors of senatorial rank chosen by himself. He had ample authority for levying troops and raising money. By the Manilian law he obtained in addition command over the whole of the East, "so that there remained scarcely a spot of land within the wide Roman dominions that had not obeyed him." These laws were opposed by the friends of the senate and by those who still cherished respect for the old constitution of the city. They were supported by Cæsar and by Cicero, and were carried by the public voice. We need not see in this action of Cæsar's a desire either to get rid of Pompeius as a rival, or to earn future favour by present support; we may rather conclude that he saw more clearly than the statesmen of his time the growth of a new order and the decay of the old, and the necessity of fresh and even perilous expedients to meet wants which had not before arisen.

After the departure of Pompeius, Cæsar held the ædileship with Bibulus. His business in this office was to take charge of the public buildings, to repair the old, to furnish such new ones as were required, and to keep the multitude in good temper by a due magnificence in their national games. This office was to Cæsar the occasion of fresh triumphs. Bibulus supplied the money, but Cæsar showed how it might best be spent, and gained the whole credit of the generosity displayed. He decorated the forum,—that small space under the Capitoline hill, on which every successive master of Rome has for good or for evil left his mark. He built, either at this or at a later time, the basilica Julia, which has again come to light in our generation, the first of those imperial erections which were imitated by his successors, and which extended the long line of colonnades and halls of justice far beyond the narrow limits of the Septimontium. He built porticoes under the Capitol for the reception of works of art, the plunder of Grecian cities; and he struck a deeper chord in the hearts of his countrymen when by his order the trophies won by Marius from barbaric kings and peoples glittered one morning freshly adorned and gilded in the place from which they had been removed by Sulla. The defenceless city was terrified at the number of gladiators which he proposed to exhibit in the Great Games, and restricted him to three hundred and twenty pairs, but he made amends by arming them with accoutrements of silver, an act of magnificence remembered even in times when the city was sated with profusion.

In the following year, 64 B.C., he was concerned in measures which show the consistency of his political character. He supported the agrarian law of Rullus (which, as far as we know its provisions, proposed to settle the poorer citizens in the waste lands of Campania and elsewhere), because, although its provisions might be defective, its principles were good, and calculated to lessen the inequality between the different members of the state. Cicero may, with the responsibility which attached to him as consul, have been right in procuring its rejection as ill-digested and premature. Cæsar's support of the impeachment of Rabirius for the murder of Saturninus thirty-seven years before, was perhaps intended to show that party feeling should never be suffered to cover the commission of a crime, to assert again the principles of democracy which had been long unpopular, and also to deter young aristocrats from imitating the excesses of Sulla. These principles once asserted, there was no need to carry the prosecution to extremities. In the year following, 63 B.C., he was elected Pontifex Maximus, a signal mark of his popularity. This office placed him at the head of the state religion. Although he did not obtain it without bribery, yet we cannot believe that he would have been elected unless the people had felt confidence in the dignity and integrity of his character, and if he had been the frivolous and abandoned libertine which some historians represent him to have been at this time. De Quincey has remarked that we are presented with a touching picture of his home life on the morning of his candidature. His mother Aurelia accompanied him to the portico of the house, with a mingled feeling of hope for his success and fear for his safety, and he answered to her expressed anxieties that he would return a conqueror or a corpse. We may believe that to his mother he owed many of his most commanding qualities. Throughout her life he treated her with deep affection and respect, and we have abundant proof that Cæsar possessed to the full that strong family affection which always accompanies a noble nature, and which the Romans of that day have by some writers been so strangely supposed to have been without.

An event was at hand of sufficient seriousness to try the mettle of the strongest. The conspiracy of Catiline has perhaps been exaggerated by the vanity of Cicero; but allowing for this exaggeration, it threatened serious danger to the state, and it affords a conclusive proof of the impotence of the Roman government at this time. We shall find the closest parallel in the military pronunciamientos of modern Spain. Catiline had probably little design beyond obtaining the best places of government for himself and his friends at any cost. If Cæsar had joined this movement he might have mastered it and directed it to his own purposes; had he been an unprincipled adventurer he might have framed for himself combinations more likely to succeed. There is no proof that Cæsar was an accomplice in this villany. Probability is against it. What we do know is that on December 5th he spoke against the execution of the conspirators. In this we have evidence of his strong common sense and political foresight. He saw that it was bad policy to break the laws in order to punish their violation. He knew also that the dead alone come back to haunt the living. "If an adequate punishment," he said, "can be devised for these men's offences let it be inflicted; if their offence transcends all punishment, let us punish them by the laws of our country." It would have been well for Cicero if he had followed this advice. Such language was thoroughly consistent in the mouth of a man who had done his best to remedy the excesses of Sulla, from which he himself had suffered, and who had lost no opportunity of inculcating political moderation. The next year, 62 B.C., Cæsar was prætor. At the close of it Pompeius returned from the conquest of Mithridates, and quietly disbanded his army. The time had not arrived for Cæsar to lay aside the toga. In 61 B.C., at the age of forty, he assumed as proprætor his first important military command, and laid the foundation of a reputation as the greatest of generals, which should never be allowed to overshadow his higher merit as a statesman and the regenerator of his country.

Before Cæsar could leave Rome for his province it was necessary that he should clear himself from the load of debt which oppressed him, and this he was enabled to do by the assistance of Crassus. A charge of insolvency has been allowed to weigh too heavily upon the character of Cæsar, and has received too much importance as a motive for his actions. It can be accounted for by supposing an over-recklessness of means to gain important public ends, and a culpable carelessness in his private interests, which are not without a parallel in statesmen of modern times, whose character is above suspicion. We have little positive information about his campaign in the Peninsula, the main operations of which were carried on in Galicia and Portugal. Cæsar appears to have exhibited on a small field the same qualities which distinguished him in a large sphere. He was proclaimed imperator by his soldiers, was voted a

triumph by the senate, and while he added to the riches of the state, was careful to render his own fortune more secure. He was a candidate for the consulship in the following year, and would gladly have conducted his canvass by proxy, while he kept his army outside the gates in readiness for his promised triumph. But Cato and the senate would not permit this violation of the law. Cæsar at once obeyed, surrendered his triumph, and obtained the consulship. He formed at this time an alliance with Pompeius and Crassus, which is generally known as the first triumvirate. It was merely a political union for common purposes, and was not, like the second triumvirate, an organized form of government. Pompeius and Crassus had been enemies, and were now reconciled by Cæsar. Cato, the champion of the senate, could not be included in this alliance, and Cicero was too vacillating in his policy and too weak in character to command the confidence of either of his former friends. The objects of the coalition were not so much to secure the personal aggrandizement of its members, as to form a strong and united front against those who wished to maintain a form of government which had become impossible, and was therefore hurtful to the state. It is possible that both Pompeius and Cæsar foresaw that under a new constitution Rome would be subject to a single head, while Crassus was not reluctant to join himself to two men, one of whom must be the ruler of the future. The democracy which raised Cæsar to power wished to obtain for its favourite the command of an army which would ensure the preponderance of his counsel in coming changes. Cæsar himself, conscious of the pressing need of important measures, and the inability of the senate to provide them, was ready with the frankest generosity to work with any one whose ideas were on this point coincident with his own. The alliance was cemented by the marriage of Pompeius to Julia, Cæsar's daughter, while Cæsar married Calpurnia, the daughter of Piso.

Cæsar's colleague in the consulship was M. Bibulus, the devoted servant of the senate, who both as ædile and prætor had submitted as a foil to set off the greatness of his companion. He offered a vain opposition to Cæsar's measures, and when he found that he could not prevent their being carried by the use of the political machinery in his power, he retired to his house and announced his intention of "observing the heavens" during the rest of his consulship, a process which ought technically to have rendered invalid all acts passed during that time. We do not possess a full account of the laws carried by Cæsar while he stood at the head of the state, but we know enough to show us that he used his opportunities to enforce the same political principles which he had always consistently professed. He ordered the proceedings of the senate to be published, and so rendered its deliberations amenable to public opinion. He passed an agrarian law similar to that of Rullus, but without the defects which had procured its rejection. He carried a measure of just relief for the *equites* or capitalists, not so much with a view of gaining their support as to make a fair concession to an important class of the community. He declared Ptolemy, king of Egypt, and Ariovistus, the German, friends of the Roman people. He made regulations for the better government of the provinces, and remedied the worst abuses under which the provinces groaned. He was the author of a great measure for the suppression of bribery and corruption amongst public functionaries, which were at that time a stigma on the state. Other resources of a similar tendency were carried by his subordinates. The senate had intended that Cæsar, on laying down his office, should be rendered as harmless as possible, and for that reason had assigned to the consuls the charge of woods and forests in Italy. The people, however, were able to protest successfully against the injustice. The tribune Vatinius obtained the passing of a law which gave to Cæsar the province of Cisalpine Gaul or Northern Italy for five years, with three legions; and the senate of its own accord added the charge of Gaul and the Alps with an additional legion. Cæsar thus obtained a field of action worthy of his genius. He stayed near the city just long enough to secure the election of his friends as consuls, and to provide against the repeal of the measures which he had passed, and then set out for the country which has ever since been identified with his name.

It is not our object to describe in detail the marvellous work which occupied Cæsar for the next eight years. No part of his life has been written with greater fulness, nor is there any for which we possess more abundant material. It must suffice to give a short sketch of the masterly campaigns by which a free and chivalrous people were reduced to absolute obedience, new countries were opened up to the knowledge and enterprize of Rome, and a form was given to the development of the civilization of France, of which she has preserved the main features to the present day. In his first campaign (58 B.C.) Cæsar gained two important victories. He defeated at Autun the Helvetii who were leaving Switzerland with the intention of settling themselves on the fertile seaboard of the Atlantic, and forced the greater number of them to return to the homes which they had left. He attacked a nobler foe in the Germans under Ariovistus, the friend of the Roman people, and in the neighbourhood of Mühlhausen cut them to pieces, and drove the few survivors across the Rhine. This mighty stream now became the boundary of the Roman empire. All central Gaul was quelled by his bold attack, and the Germans were cowed into quietude, but the Belgæ, a mixed race of warlike qualities, remained unsubdued. In the next year (57 B.C.) Cæsar marched against them, and scattered their confederacy to the winds. The Nervii made a better stand, and Cæsar was forced to expose his life, and to fight like a common soldier. But they, too, sustained a crushing defeat, and the submission of the Veneti and the coast cantons to Publius Crassus left only the northern tribes, such as the Morini and Menapii, independent of the Roman rule. The work of Crassus had been imperfectly performed, and in the following year (56 B.C.) the Veneti threw off the yoke. The whole coast from the Loire to the Rhine joined the insurrection. Cæsar hurried from Italy, and taking measures for the security of the north and south, prepared to attack the Veneti by sea. Victorious by sea as by land by new and skilful devices, he disabled their powerful fleet, and sold the defeated captives into slavery to a man. The Morini and Menapii alone remained unconquered, protected more than any thing else by the natural strength of their country. Cæsar marched against them, but was forced to desist from the attack. With this exception, the whole of Gaul had been reduced to obedience in three campaigns. Cæsar now turned his arms against the Germans. He cut to pieces the Usipetes and Tenchteri, who had crossed the lower Rhine, after treacherously depriving them of their leaders, who had come of their own free will into his camp. There is no excuse for this violation of international law, which was very properly rebuked by Cato in the senate; but Cæsar might have replied that the precedents of Roman history had not inculcated a spirit of fairness or forbearance towards alien enemies. He built a bridge across the Rhine, and remained eighteen days on the other bank. The same year (55 B.C.) witnessed his first expedition to Britain, whither he was led partly from curiosity, and partly by a desire to detach from the Celtic confederacy a land which was the sure asylum of political refugees. The islanders made a brave resistance, and Cæsar was compelled to retreat. He

was so much dissatisfied with the result of the campaign, that he made great preparations for renewing the attack in 54 B.C. On this occasion he penetrated further into the interior and crossed the Thames, but Cassivellaunus, to whom the defence of his country had been entrusted, followed the Roman army with his war chariots, and successfully impeded their operations. Cæsar, before he left, imposed a tribute and demanded hostages, but it was difficult to conceal that he retired discomfited from a land which he had to all appearance seriously intended to subdue. The next two years witnessed the final struggle of the Gauls to regain their freedom. Inspirited by the resistance of the Germans and the Britons, and inflamed by the death of Dumnorix, they determined to make a simultaneous attack on the Roman garrisons, which this winter were scattered more widely than usual. Q. Titurius Sabinus and L. Aurelius Cotta were the first assailed. Deceived by Ambiorix, king of the Eburones, their whole division was annihilated. A similar attack was made upon Q. Cicero in the territory of the Nervii, but Cæsar was near enough to bring assistance. The insurrection was checked and a terrible vengeance exacted from the Eburones. Acco, prince of the Carnutes, was executed by the victors. His death spurred his tribesmen to greater exertions. In the winter of 53–52 B.C. they roused the spirit of their countrymen. The post of honour was held by the Arverni, under their prince Vercingetorix, an heroic leader, whose name casts lustre on this last vigorous but hopeless struggle. A new plan of defence was adopted. Instead of defending every town against the Romans, it was determined to burn those places which could not be held, and to concentrate their forces in those strong positions which gave a good hope of success. Thus the campaign clusters round the names of Avaricum, Gergovia, and Alesia. The first of these towns (Bourges) was taken in the spring of 52 B.C. The second, the capital of the Arverni, was attacked by Cæsar in vain, and an attempt to remedy the disaster led to a more decisive defeat. The star of Cæsar began to pale. The Hædui, who had before hesitated to join the insurrection, now avowed their hostility, and the whole nation rose like one man to cast off the yoke of the invader. The final struggle was concentrated round the hill-town of Alesia. Vercingetorix, faithful to his tactics, took refuge here with 80,000 infantry and 25,000 horse. Cæsar had been able to join his forces with Labienus, and invested the hill on every side. The mighty masses of the Gallic landsturm crowded from all quarters to release their champion. Cæsar was at once besieger and besieged. In this supreme crisis his genius triumphed. The provisions of Alesia were exhausted. Cæsar repulsed the double attack on both his lines, and Vercingetorix, disdaining to fly, delivered himself into the power of his conqueror. Had the result been otherwise, it is possible that Cæsar might have been driven from Gaul, and the floods of barbarians pouring down over Italy would have anticipated history by five hundred years. The following year (51 B.C.) saw the final pacification of the country. In eight years Cæsar had done his work most thoroughly. Gaul never afterwards attempted to revolt, but remained a rich and contented member of the Roman empire. On no subject-country was impressed more completely the language, laws, and civilization of its masters. If it had been possible so gradually to extend the bounds of Roman dominion as to convert dangerous hordes of undisciplined tribes into contented allies, Cæsar shows us how it might have been done. Even the patriotism of an emperor of the French cannot but admit that it was better for his country that Cæsar should conquer than Vercingetorix.

Whilst Cæsar had been engaged in the conquest of Gaul, the bands which held the triumvirate together had gradually become loosened. The three members of the coalition had met at Lucca in 56 B.C., and had arranged that Cæsar's command in Gaul should be continued for another five years; that Pompeius and Crassus should be elected consuls for 55 B.C.; and that on the expiration of their office Crassus should have Syria for his province and Pompeius the two Spains. These arrangements were carried out, but in September 54 B.C. Julia, the daughter of Cæsar and the wife of Pompeius, died. A project for a double alliance of a similar kind was rejected by Pompeius. In 53 B.C. Crassus was slain in Parthia. In 52 B.C. it became clear that Pompeius was asserting his independence, was drawing nearer to Cato as an ally, and was becoming more disposed to act as the champion of the senate. From this time till the outbreak of the civil war, it was more and more evident that a collision between the two great rivals was inevitable, although Cæsar did his best to avert the catastrophe. The details of the final quarrel are complicated and difficult to understand. By the law of Vatinius Cæsar's command expired in 54 B.C., by that of Trebonius it was continued till 49 B.C. It is comparatively unimportant whether his *imperium* would determine at the end of February or the end of December in that year. It had been arranged among the triumvirs that Cæsar should be consul in 48 B.C. According to strict Roman law he must announce himself personally as a candidate, which he could not do whilst he was still in command of an army. Pompeius had, in 52 B.C., secured to Cæsar exemption from the restriction by a tribunician law, but there was some doubt whether this had not been rendered invalid by a subsequent enactment. In the same year it had been decreed that no one should hold a governorship until five years had elapsed from his laying down the office of consul or senator. In 51 B.C. the question of appointing a successor to Cæsar came before the senate, and it was finally determined that his command should come to an end on the Ides of November, 49 B.C. The object of the senate was that some interval should elapse between Cæsar's consulship and proconsulship. Cæsar knew that he could not trust himself to the power of his enemies, but he displayed his usual moderation. He gave up the two legions which were demanded from him for the Parthian war, and by means of Curio, whom he had won over to his side, he proposed to the senate that Pompeius and himself should simultaneously disarm. To the surprise of the aristocratic party the motion was carried. Marcellus refused to accept the decision on the plea that Cæsar was bringing his army into Northern Italy. He called on Pompeius to put himself at the head of the legion in Campania, and declare war against the invader. Cæsar made one more ineffectual attempt at compromise. The propositions brought by Curio to the new consuls on January 1, 49 B.C., were contemptuously rejected, and Cæsar was peremptorily ordered to resign his command. Although he had only one legion with him at Ravenna he could not hesitate. He crossed the frontier of Italy, and arrived at Ariminum.

Cæsar crossed the Rubicon in the middle of January, 49 B.C., and he was murdered on the Ides of March, 44 B.C. During this space of a little over five years he crushed in every part of Europe the armies of his enemies, and laid deep and strong the foundations of the imperial power of his successors. He spent barely fifteen months of this time in Rome. He did not now, as his enemies had expected, march at once upon the capital. He observed that a surer way lay open to him of securing the possession of Italy by seizing the central heart of the peninsula, which in ancient as in modern times has held out delusive hopes to patriot people and rebellious kings of taming the proud tyranny of the Tiber city. Here the solitary church of St Pelino marks the site of Corfinium, once the destined home

of Latin independence, and the city of Aquila languishes under the snows of the Gran Sasso d'Italia, a monument of the vain but chivalrous struggle of the emperors against the popes. Into these upland valleys, lying midway between the two seas, Cæsar dashed with irresistible force, and town after town fell before him and his lieutenants. Pompeius moved slowly towards Brundusium, whither he was followed by the conqueror. Cæsar was unable to prevent the embarkation of his troops for Greece, but when by the end of March he reached Rome he was already the undisputed master of Italy.

In his next operations Cæsar displayed to a marvellous degree his ability and resources, and showed how the success of his projects depended entirely upon his personal exertions. His lieutenants were seldom fortunate; but, like Napoleon, his presence was worth an army, and, like Frederick the Great, he knew how to spring at once from the deepest embarrassments to the triumph of victory. At Ilerda his army was cooped up between two rivers, and all communication with Rome cut off. By a clever stratagem he surrounded Afranius and Petreius, and compelled them to surrender. At Dyrrachium he was in a worse position, encamped on a barren ridge, encompassed by a far superior army on the land side, and cut off from the sea, which was in the power of his enemies. Even when he had received his reinforcements he could not hold his own against greater numbers. Yet he was able to take advantage of the first mistake of Pompeius, and the victory of Pharsalus was crushing and complete. At Alexandria, where his stay is difficult to account for even by the attractions of Cleopatra, he nearly fell a victim to a popular tumult, yet he was no sooner extricated from his difficulties than he marched into Asia, saw and conquered the son of the great Mithridates, and placed the affairs of the East on a basis of security. In Africa he had allowed the Pompeians to attain a dangerous efficiency of organization by his delay at Alexandria, and it was only through the extremest caution that he was enabled to assemble his tardy forces. But the battle of Thapsus deprived the senate of their last and noblest champion, and left Cæsar the master of the Roman world. The capitulation of Ilerda took place in August 49 B.C., the winter of 49–48 B.C. was passed on the coast of Illyria, the battle of Pharsalus was fought on August 9, 48 B.C., and Pharnaces was defeated at Zela on August 2, 47 B.C. Cæsar's stay at Rome was chequered by the mutiny of the legions in Campania, and the difficulty of assembling his troops; yet he was able to land in Africa before the end of 47 B.C., and he won the victory of Thapsus on April 6, 46 B.C. In July of that year he entered Rome as conqueror, and could now find leisure to govern the world which he had subdued.

During four separate days he celebrated four triumphs over Gaul, Egypt, Pontus, and Africa. Vercingetorix, who struggled in vain to save his country, Arsinoe the sister of Cleopatra, and the son of Juba, king of Mauretania, followed his triumphal car. The citizens were publicly feasted at the dictator's expense, a distribution of money was made to the poor and the strange magnificence of the games celebrated in memory of his daughter Julia fulfilled the promise of the splendour of his ædileship. One more struggle was necessary before peace was finally secured. The sons of Pompeius, Cnæus and Sextus, had collected a large army in Spain, which had always been the stronghold of their cause. The battle of Munda, fought on March 17, 45 B.C., resulted in their entire defeat, but Cæsar was compelled to be absent from the capital from the end of 46 B.C. till September 45 B.C.

It may be questioned whether Cæsar was himself anxious to receive the title of king, which his admirers were without doubt desirous to force upon him. Such a title would have added but little to his real power over every department of the state. After the expulsion of the kings the Roman constitution came eventually into such a form that, while every interest was represented, the whole power could never come into the hands of one individual. The two consuls were a check upon each other, and they were themselves subordinate to the senate. The tribunes occupied an entirely different position to the other magistrates, and defended the interests of the mass of the citizens. The senate itself was controlled by the censor, and the working of the political machine was so ordered that a single magistrate could, either by his personal objection, or by a skilful use of divine sanctions, obstruct any measure of a rash or unusual character. The chief officers of the state were occasionally suspended by the appointment of a dictator for extraordinary emergencies, but it had probably never occurred to any statesman that the whole of these well-balanced and often conflicting authorities might come to be concentrated in the person of one man. Yet it was by these means that the republic became a monarchy, and that Cæsar became emperor. He was five times consul and four times dictator, and at his death was dictator elect for life. He had the tribunician power conferred upon him, which, among other advantages, rendered his person inviolable. Instead of the censorship he was invested with the new office of *præfectus morum*, which he used to curb the luxury and extravagance induced by the influx of conquered wealth. His opinion was, as *princeps senatus*, asked first in the senate; his effigy was struck upon the coins. The exaggerated and half-divine honours which the servility of the senate invested added but little to his power, but the title of *imperator*, with which many a successful general had been saluted on the field of battle, was now *prefixed* to his name as a permanent addition, and has remained, together with the family name of him who first bore it, as the title of highest sovereignty throughout the civilized world.

The complex of authorities thus placed in his hands he used in a manner to justify the confidence of those who entrusted them to him. It is difficult to give an accurate account of his administration. Mommsen, in the brilliant chapter which at present closes his history of Rome, has scarcely distinguished with sufficient care between Cæsar's intentions and his acts, and between his measures and those of his successors. Yet we have ample evidence that much was done and much more conceived. If we follow the authority of Suetonius we find that he reformed the calendar by intercalating three months in the year 46, and making arrangements for the future, which lasted unchanged till the 16th century. He increased the number of the senate to nine hundred, and made it more thoroughly representative of all classes and all parts of the empire. He increased the number of the magistrates, did his best to heal the wounds left by the civil war, and reformed the courts of justice. He confined donations of corn to the poorer citizens, and while by the rebuilding of Carthage and Corinth he found a refuge for many who would have starved at home, he did his best to prohibit absenteeism, and to discourage the tillage of the soil of Italy by slaves. He gave the rights of citizenship to men of science and to professors of liberal arts, enforced the laws without favour, and attempted with little success to restrain the luxury of the age. He prepared the way for the work of his successor, who found Rome of brick and left it of marble. He intended to codify the law, and to provide public libraries of Greek and Latin works, the care of which he entrusted to Varro, the most learned of the Romans. He is credited with the design of draining the Pontine marshes, a work yet to be performed; of converting the Fucine lake into a fertile plain, an enterprise begun by Claudius and completed by Prince Torlonia; of

piercing the isthmus of Corinth; of making a road from the Adriatic to the Tiber; and further, of subduing the Parthians, and returning through Scythia and Germany into Italy, after extending the limits of the empire to the stream of the ocean.

However this may be, it is certain that at the time of his death he was preparing an expedition against the Parthians. It is useless to speculate whether his absence from the city would have been short or long. There is evidence that he did not feel at his ease in the capital, that he considered his personal work to be accomplished, and that his plans could be better carried out by his successor. Yet nothing can excuse the shortsighted wickedness and folly of those who murdered him. We need not repeat the well-known story, how in the Ides of March, 44 B.C., Cæsar was murdered in a meeting of the senate, and fell at the feet of the statue of Pompeius, pierced with wounds from head to foot, only one of which was fatal. There is no reason to believe that the conspiracy had been long in preparation, or that it was motived on the one hand by a desire for personal aggrandizement, or still less, on the other, by a devoted patriotism. It began in spite, and continued in folly. A very slight degree of political foresight might have convinced those who assented to the plot that the people would not be on their side, and that they would precipitate the very conclusion which they desired to avert. Those who deified Brutus in the French Revolution knew but little of Roman history, or confounded him with the expeller of the Tarquins. Dante is a better judge, whose ardent love of liberty did not blind him to the necessity of a strong and united government for his native land. The divine poet relates to us with an appalling realism, that in the centre of the earth, in the bottom of the pit of hell, Lucifer holds in his three mouths the three greatest malefactors the world has ever seen,—Brutus and Cassius, who betrayed their sovereign and their country, and Judas Iscariot, who betrayed his Master with a kiss.

Under different circumstances Cæsar might have won as great a reputation as a man of letters as he has acquired as a general and a statesman. He was fully aware that a change in the literary language of his countrymen was as necessary as in their government and constitution. The rude though vigorous dialect of Plautus, or even of Varro, was not suited to be the organ of civilization throughout a subject world. A widespread knowledge of Greek had made the Romans aware of their own deficiencies, and the united efforts of all men of culture to give form and refinement to the Latin tongue culminated in the glories of the Augustan age. Cicero and Livy, Virgil and Horace, have remained as examples of Latin style during the whole of the Christian era. The language in which they wrote must have differed widely from anything which was spoken by their most cultivated contemporaries. It is not unreasonable to feel some regret that the cultivated language did not follow a course of development more suited to its inherent character, and that Lucretius and Cæsar were not adopted by the rhetoricians of the empire as models for precept and imitation. The excellence of the Latin language lies in its solidity and precision; its defects lie in a want of lightness and flexibility. Lucretius found it sufficient to express with admirable clearness very complex philosophical reasoning, and Cæsar exhibited its excellencies in their purest and chastest form. It is a misfortune that the *Commentaries* are not more often studied as a masterpiece of literature, but are relegated by the irony of fortune to the lower forms of schools. Their style is faultless, not a word is thrown away or used with a doubtful meaning, every expression is in its place, and each touch serves to enhance the effect of the whole. Had Cæsar been writing history instead of military memoirs, he might have allowed himself greater freedom of ornament. We know, from his treatise on grammar (*De Analogia*), often quoted by grammarians, that his success in literature was the result of careful study and meditation. As an orator he was acknowledged to be second to Cicero alone, and he is one of the few men in history who have quelled a rebellion by a speech.

In this sketch of Cæsar's life we have found but little to blame, and have been able to add few shadows to the picture. The stories which the jealousy of contemporaries have preserved against him are too frivolous to be recorded, while the dignity, sweetness, and nobleness of his character cannot be concealed. We have preferred rather to attempt to construct from very imperfect materials some faint resemblance of the marvellous personality of him whom the genius of Shakespeare rightly recognized as "the foremost man of all this world."

The principal ancient authorities for the life of Cæsar are the biographies of Plutarch and Suetonius, the letters and orations of Cicero, and the Commentaries on the Gallic and Civil Wars written by or ascribed to Cæsar himself. To these may be added Appian's *Civil War*, Dion Cassius, Velleius Paterculus, Sallust's *Catiline*, the *Epitomes* of Livy, and Lucan's *Pharsalia*. His life has been perpetually narrated in ancient and modern times, and has been the battle-field of imperialists and republicans. For English readers, the account given by Merivale, both in his *History of the Romans under the Empire*, and in the *Fall of the Roman Republic*, is readable and adequate; the fullest and fairest examination of the original authorities is in Long's *Decline of the Roman Republic*, vols. iii.–v. The article in Smith's *Biographical Dictionary* is excellent, but by far the most brilliant picture of Cæsar's character and work is to be found in Mommsen's *History of Rome* (published 1856, translated into English 1866). Mommsen is extremely favourable to Cæsar, but unfair to his opponents. The *Histoire de César* of Napoleon III., which extends only to the outbreak of the civil war, is especially valuable from the maps and plans which accompany it. The German student will find a full and satisfactory repertory of all that is known about the subject in Drumann, *Geschichte Roms*. (O. B.)

CÆSAR, Sir Julius (1557–1636), a learned civilian, descended by the female line from the Dukes de' Cesarini in Italy, was born near Tottenham in Middlesex. He was educated at Oxford, and afterwards studied at the university of Paris, where in the year 1581 he was created doctor of the civil law. Two years later he was admitted to the same degree at Oxford, and also became doctor of the canon law. He held many high offices during the reigns of Elizabeth and James I., and for the last twenty years of his life was master of the rolls. He was so remarkable for his bounty and charity to all persons of worth, that it was said of him that he seemed to be the almoner-general of the nation. His manuscripts, many of which are now in the British Museum, were sold by auction in 1757 for upwards of £500. See E. Lodge, *Life of Sir Julius Cæsar*, 1810.

CÆSAREA, the name of two towns in Palestine:—

I. Cæsarea Palestina, now Kaisaryah, the Roman metropolis of Palestine, 30 miles north of Joppa, and about the same distance north-west of Jerusalem. It was built about 22 B.C. by Herod, on the site of an earlier town called Turris Stratonis. Vast sums of money were spent in the erection of its more important buildings, among which were a temple dedicated to Cæsar, a theatre, and an amphitheatre. The most stupendous work, however, was the semicircular mole, constructed of immense blocks of stone brought from a great distance, and sunk to the depth of twenty fathoms in the sea. It protected the port on the south and west, leaving only a sufficient opening for vessels to enter from the north, so that within the enclosed space (which, according to Lieutenant Conder, measures 300 yards across) a fleet might ride in all weathers in perfect security. The site of the city is now marked by an extensive mass of ruins, among which may still be traced the substructions of all the above-mentioned buildings, as well as those of

the cathedral built by the Crusaders, an old fortress on the site, it is supposed, of Herod's "Drusus tower," two aqueducts, and a variety of minor structures. The line of the walls of the mediæval town can still be made out, and in some parts that of the more extensive Roman works. The southern part of the mole is also intact. Cæsarea was made the seat of a colony by Vespasian, and took for a time the title of Flavia, but its earlier name was maintained to the time of its complete decay. In the 4th century it was the see of Eusebius, the church historian, and during the crusading period was one of the chief posts of the invaders.

II. Cæsarea Philippi, 95 miles north of Jerusalem, and about 35 south-west of Damascus, situated at the southern base of Mount Hermon, near one of the sources of the Jordan. It has been identified with Baalgad or Beth-Rehob, and was certainly known for a long time as Panium or Panias, the cave at the foot of the mountain being dedicated to Pan. Herod erected a temple to Augustus in the neighbourhood; and the town was much enlarged and beautified by Philip the Tetrarch, who named it Cæsarea in honour of Tiberius the emperor, adding the cognomen of Philippi to distinguish it from the town last noticed. It continued to be a place of some importance till after the time of the Crusades, and was successively the seat of a Greek and a Latin bishopric. Its site is occupied by the modern Bâniâs or Panias, a paltry and insignificant village, with numerous ruins in the vicinity. On the top of a conical hill above the village stands the castle of Subeibeh, which possibly dates from the time of the Phœnicians, and has been one of the most remarkable fortresses in Palestine from that day to this.

CÆSAREA, or Kaisarieh, a city in Asiatic Turkey, formerly one of the most important places in Cappadocia, and at present the chief town of a sanjak in the province of Karaman, situated on the Kara-su, between two spurs of the Mons Argæus, in 38° 42′ N. lat. and 35° 20′ E. long. It is the seat of an Armenian bishop, and the commercial centre of an extensive and highly populous district; its markets are well supplied with European goods, and its inhabitants noted for their enterprise. Its principal manufactures are cotton and morocco leather. Recently it has become the scene of a considerable Protestant movement, and a girls' school, the first in the city, has been established. The ruins of an earlier Mahometan town are immediately contiguous, and a little to the south are the ruins of the ancient city. The latter was known originally as Mazaca, and afterwards as Eusebia; and only received its present name from the Emperor Tiberius. It was for a time the seat of the Cappadocian kings; but it suffered greatly at the hands of Tigranes, who carried off its inhabitants to his new city of Tigranocerta. Under the later Roman empire it recovered to such an extent that it was supposed to contain 400,000 inhabitants when it was captured by Sapor in the reign of Valerian. The present population, of which about two-thirds are Turks and the rest mainly Armenians and Greeks, is estimated at about 10,000.

CAFFRARIA See Africa (vol. i. p. 263) and Kaffraria.

CAGLI (the ancient *Calles*), a walled town of Italy, in the province of Pesaro e Urbino, at the confluence of the Cantiano and Busso, the former of which is crossed there by an ancient Roman bridge. It is the seat of a bishop, and has a cathedral and several churches and monasteries, in one of which, Santo Domenico, is preserved a famous fresco by Giovanni Santi, the father of Raffaelle. The principal occupation of the town is the manufacture of leather. Population 10,213.

CAGLIARI, the capital of the island of Sardinia, and chief town of its southern province, is situated in the recess of the bay to which it gives its name, not far from the mouth of the River Mulargia, in 39° 33′ 14″ N. lat. and 9° 7′ 48″ E. long. It has a splendid appearance from the sea, occupying as it does the slope and summit of a hill, which is crowned by a noble castle. This building gives the name of Castello, or, in Sardinian, Casteddu, to the district containing the vice-regal palace, the cathedral, the university, the theatre, the chief mansions of the nobility, and the public seminaries. To the west of the Castello lies the district of Stampace, with the Corso, and to the east that of Villanuova with its pleasant promenades,—both consisting for the most part of narrow, irregular, and ill-paved streets, but the former inhabited by the wealthier citizens. The slope between the castle and the bay is occupied by the Marina, a well-built quarter, containing the residences of the merchants and consuls, the bonded warehouses, and the lazaretto; while to the west of the town is the spacious suburb of St Avandrace, nearly a mile in length. The university, which possesses the four faculties of theology, law, medicine, and arts, was founded in 1596 by Philip of Spain, was restored in 1720, and was remodelled in 1764. It has a library of upwards of 22,000 volumes, and numbers from 100 to 200 students. Besides the cathedral, which was built by the Pisans during the 14th century (though the present front only dates from 1703), Cagliari contains about thirty churches and twenty convents, of which the Capuchin monastery is interesting for remains of Roman reservoirs. There is a considerable museum both of antiquities and natural history, as well as a recently erected observatory; and the benevolent institutions comprise an orphanage, and a large civil hospital, under the superintendence of a medical board and the sisters of mercy, with a separate wing set apart for the accommodation of lunatic patients. There are also in the town a mint, an extensive custom-house, and barracks. Cagliari is the see of an archbishop, and the seat of the Sardinian Cortes, and of the judicial court for the southern division of the island. The bay, formed by the projection of Cape Carbonara and Cape Pula, and stretching inland for a distance of 12 miles, with an extreme width of 24 miles, contributes greatly to the commercial importance of the city; and the harbour, situated at the south angle of the wall of the Marina quarter, is one of the safest in the Mediterranean, being well sheltered from every wind except the south. Frequent proposals have been made to extend the area by the construction of a breakwater, but this has not as yet been effected. Cagliari is the chief port of Sardinia, and possesses by far the greatest part of the export trade, which principally consists of corn, fruits, oil, wine, cork, lead, and a few native manufactures. Most important of the last class is salt, procured, at the rate of 683,000 quintals per annum, from the salt-pans to the west of the town. In 1873 the total value of exports from the province, most of which pass through the port, was £519,234; while the imports of the same year were of the value of £368,028. There is regular steam communication with Naples, Leghorn, and Genoa, as well as less frequently with other ports. The railway from Cagliari to Iglesias, a distance of 33½ miles, opens up the most important lead mines at present in operation, and a line of 58½ miles leads to Oristano. There is a submarine telegraph to Malta and another to Bône in Algeria. The climate of the town, in spite of the proximity of the salt swamp already mentioned, is excellent; and water, the want of which was formerly severely felt, is now supplied by an English company. Population in 1871, 33,039.

The modern city occupies the site of the ancient *Carales* or *Caralis*, which was founded by the Carthaginians, and passed into the hands of the Romans after the first Punic war. Of the buildings erected by the latter people there are several extensive remains,—those of an amphitheatre cut out in great part from the rock, a large aqueduct, a circular temple, &c.; while in the suburb of St Avandrace are

numerous Roman sepulchres, of which the most interesting is that of Atilia Pomptilla. In the civil war between Cæsar and Pompey, and during the empire, Cagliari was an important naval station; and, though it never obtained the status of a Roman colony, its inhabitants received the right of citizenship. Under Tiberius its population was augmented by the introduction of 4000 Jews, whose descendants were only expelled by the Spaniards in 1492. After the fall of the Western empire the city continued under the Vandals to be the capital of the island, and retained its importance during the Middle Ages. In 1353 the Genoese were disastrously beaten in the neighbouring sea by the Aragonese and the Venetians. In 1708 the town was bombarded by the English under Admiral Lake; in 1717 it was captured by the Spaniards; in 1779 it suffered from a great famine; and in 1793 it was bombarded by the French. From 1799 to 1815, while Savoy was in the hands of the French, Cagliari afforded a residence to the king of Sardinia.

CAGLIARI, PAOLO. See VERONESE.

CAGLIOSTRO, ALESSANDRO, COUNT (1743-1795), the arch-impostor of modern times, was born at Palermo in 1743. Joseph Balsamo—for such was the count's real name—gave early indications of those talents which afterwards gained for him so wide a notoriety. He received the rudiments of his education at the convent of Cartagirone; where, being employed to read to the monks during dinner, he scandalized the good fathers by repeating the names and detailing the adventures of the most notoriously profligate females of his native town. For these and similar misdeeds he was expelled from the convent and disowned by his relations. He now signalized himself by the ingenuity with which he contrived to perpetrate crimes without exposing himself to the risk of detection. He began by forging tickets for the theatres; then he forged a will; he next robbed his own uncle, and ultimately committed a murder. For the last offence he was imprisoned and brought to trial; but through a defect in the evidence, he escaped with his life. On his release he engaged a goldsmith, by name Marano, to assist him in searching for a hidden treasure,—Marano paying 60 oz. of gold in advance to defray expenses. On arriving at the cave where Joseph declared the treasure to be, six devils, prepared beforehand, rushed out upon the goldsmith, beat him soundly, and left him insensible. Dreading the vengeance of Marano, Balsamo quitted Sicily, and visited in succession Greece, Egypt, Arabia, Persia, Rhodes (where he took lessons in alchemy and the cognate sciences from the Greek Althotas), Malta, Naples, Rome, and Venice. At Rome he married a beautiful but unprincipled woman, with whom he travelled, under a variety of names, through the various countries of Europe. It is unnecessary to recount the various infamous means which he employed to support himself during his travels. At Strasburg he reaped an abundant harvest by professing the art of making old people young; in which pretension he was seconded by his wife Lorenza Feliciani, who, though only twenty years of age, declared that she was sixty, and that she had a son a veteran in the Dutch service. In Paris he was implicated in the affair of the diamond necklace; and though he escaped conviction by the matchless impudence of his defence, he was imprisoned for other reasons in the Bastille. On his liberation he visited England, where he succeeded well at first; but he was ultimately outwitted by some English lawyers, and was confined for a while in the Fleet. Leaving England, he travelled through Europe till he arrived at Rome, where he was arrested in 1789. He was tried and condemned to death for being a Freemason, but the sentence was afterwards commuted to perpetual imprisonment. He died in the fortress prison of San Leo in 1795. The best account of the life, adventures, and character of Joseph Balsamo is contained in Carlyle's *Miscellanies*. Dumas's novel, *Memoirs of a Physician*, is founded on his adventures. See also a series of papers in the *Dublin University Magazine*, vols. lxxviii. and lxxix.

CAGNOLA, LUIGI, MARQUIS (1762-1833), a celebrated architect, a native of Milan. He was sent at the age of fourteen to the Clementine College at Rome, and afterwards studied at the university of Pavia. He was intended for the legal profession, but his passion for architecture was too strong, and after holding some Government posts at Milan, he entered as a competitor for the construction of the Porta Orientale. His designs were commended, but were not selected on account of the expense their adoption would have involved. From that time Cagnola devoted himself entirely to architecture. After the death of his father he spent two years in Verona and Venice, studying the architectural structures of these cities. In 1806 he was called upon to erect a triumphal arch on the occasion of Eugène Beauharnais's marriage with the princess of Bavaria. The arch was of wood, but was of such beauty that it was resolved to carry it out in marble. The result was the magnificent Arco della Pace in Milan, one of the grandest erections of modern architecture, surpassed in dimensions only by the Arc de l'Étoile at Paris. Among other works executed by Cagnola are the Porta di Marengo at Milan, the Campanile at Urgnano, and the chapel of Santa Marcellina in Milan. He died on the 14th of August 1833.

CAGOTS, a people found in the Basque provinces, Béarn, and Gascony. During the Middle Ages they were popularly looked upon as crétins, lepers, heretics, and even as cannibals. Entirely excluded from all political and social rights, they were not even allowed to enter a church but by a special door, or to remain except in a part where they were carefully secluded from the rest of the worshippers. To partake of the mass was never permitted them. They were compelled to wear a distinctive dress, to which, in some places, was attached the foot of a goose or duck (whence they were sometimes called *Canards*). And so pestilential was their touch considered that it was a crime for them to walk the common road barefooted. The only trades allowed them were those of butcher and carpenter, and their ordinary occupation was wood-cutting. Their language is merely a corrupt form of that spoken around them; but a Teutonic origin seems to be indicated by their fair complexions and blue eyes. Their crania have a normal development; their cheek-bones are high; their noses prominent, with large nostrils; their lips straight; and they are marked by the absence of the auricular lobules. Upon the last peculiarity great stress is laid by anthropologists, and it is held to point to a Gothic origin. The common opinion of authorities is that this people are descendants of the Visigoths, and M. Michel derives the name from *caas* (dog) and *Goth*. But opposed to this etymology is the fact that the word *cagot* is first found in the *for* of Béarn not earlier than 1551, while the older MSS. call these peoples *Chrétiens*, or *Chrestiaas*, a term which, on this hypothesis, would have its origin from the fact that these Visigoths, left behind in Aquitaine, were Christians, while the Gascons were still Pagans. On the contrary, M. Marca, in his *Histoire de Béarn*, holds that the word signifies "hunters of the Goths," and that the Cagots are descendants of the Saracens. Again, some would make them descendants of the Albigenses; others of crétins (they are sometimes called Crétins); and others of lepers, declaring their name to be connected with the Celtic *caccod* and the Spanish *gafo*. In the laws of Navarre (1704) they are indeed styled *gaffos*, and treated as lepers; but in those of Béarn, they are clearly distinguished from them.

Small communities, believed to be of the same race, and existing in a similar social condition, being classed with them as "*les races maudites*," are to be found in Maine, Anjou, Poitou, and Aunis, under the name of *Colliberts* (a word said by Ducange to be derived from *cum* and *libertus*, and signifying "neither free nor slave"); in Brittany, under the names *Cahets* *Caqueux*, *Cacous*,

Caquins, or *Cacvas*; in Auvergne, under that of *Marrons*. Considerable numbers of the Colliberts still live in the *Marais mouillés de la Sèvre*; and the Cagots may be found round Jaca, in Guipuzcoa, in Navarre, at Cherbitua d'Anhauze in the valley of Azun, near Saint-Jean-Pied-de-Port and Saint-Jean-le-Vieux, and in the villages of Agotetchiac, Tailhapé, and Ainchicharburu, but in largest numbers in Labour, in the Basque arrondissement of Bayonne.

See Michel, *Histoire des races maudites*; L'Abbé Venuti, *Recherches sur les Cahets de Bordeaux*, 1754; *Bulletins de la Société Anthropologique*, 1861, 1867, 1868, 1871; *Annales medico-psychologiques*, Jan. 1867; M. Lagneau, *Questionnaire sur l'ethnologie de la France*.

CAHORS, a town in the south of France, formerly the capital of Cahourcin or Upper Quercy, and now of the department of Lot, on the high road between Paris and Toulouse, 358 miles S.W. from Paris, and 60 miles north of Toulouse, in 44° 27′ N. lat., 1° 24′ E. long. It stands on the right bank of the River Lot, on a rocky peninsula formed by a bend in the stream, and communicates with the opposite shore by three bridges,—one, the Pont Valendré, built in the 13th century, and surmounted by three massive towers. In the more ancient part of the town the streets are narrow and the houses antique; but in the modern and more elevated quarter there are many handsome buildings, with terraces which command an extensive view. The most remarkable building is the cathedral, built in the 11th or 12th century, and occupying the site, if not actually consisting of the remains, of an ancient Roman temple. Besides it, there is the theological seminary, the prefecture (formerly an episcopal palace), an academy, a theatre, a public library, and a monument erected to Fénelon in front of the cathedral. Cahors is the see of a bishop, and the seat of judicial and commercial tribunals of the first class. Its university, founded by Pope John XXII. in 1332, was incorporated with that of Toulouse in 1751. The principal articles of manufacture are stoneware, cotton-yarn, woollen stuffs, and paper; and it has a considerable traffic in oil, hemp, flax, hides, truffles, and a strong deeply-coloured wine, which is made in the neighbouring districts. Population of the town in 1872, 13,061, and of the commune 14,593.

Cahors is the ancient *Divona*, afterwards called *Civitas Cadurcorum*, from the Celtic tribe of which it was the capital, and still exhibits traces of its greatness during the Roman sway. The most conspicuous remains are those of an immense aqueduct, which conveyed the water to the city from a distance of about 19 miles by a precipitous route along the mountain sides, and crossed the valley of Larroque-des-arcs on a bridge 180 feet high. There are also remains of baths and a theatre, a marble altar in front of the prefecture (erected, according to the inscription, in honour of Lucterius Leo); and a celebrated fountain, supposed to be the fountain Divona, and now called Des Chartreux, from the Carthusian convent to which it has been attached.

After the decline of the Roman empire Cahors passed in succession into the hands of the Goths the Franks, the Saracens, and the Normans; and in the 12th century it was the subject of severe fighting between the English and French. In 1572 the Protestant party in the town were strong enough to prevent their fellow-citizens following the example of Paris; and yet a few years later, in 1580, we find the opposition to Henry of Navarre so violent that he only made himself master of the place after several days of conflict. The bishops of Cahors, who date from the 4th century, had formerly also the title of count, and used to lay their sword and gauntlets on the altar when about to officiate. During the Middle Ages the town is said to have been a great seat of the Caorsini (Cawertschen or Cauder-Wälsche), who preceded the Lombards as usurers and money-changers.

See Chaudruc de Crazannes, *Coup d'œil sur les monuments historiques du département du Lot*; Dufour, *La commune de Cahors au moyen âge*, 1846.

CAILLE, Nicolas Louis de la. See La Caille.

CAILLIÉ, or Caillé, René (1799–1838), a French traveller in Africa, was born in 1799 at Mauzé, and died in 1838. His school education extended no farther than reading and writing; and at the age of sixteen he commenced his career by a voyage to Senegal. But already *Robinson Crusoe* had kindled within him an enthusiastic admiration for the life of the discoverer; and in 1827, having collected 2000 francs by toiling on an indigo plantation, he set out on his most important mission. From Kakundy he travelled east by Cambaya, Kankan, Time, and Tangrera, and north-east by Donasso as far as Galia, through a hitherto unvisited district; and from Galia he passed through the country explored by Mungo Park to Timbuctoo, which he reached on April 20, 1828. He thus won the prize of 10,000 francs offered by the Geographical Society of Paris to the first traveller who should gain exact information of Timbuctoo, to be compared with that given by Mungo Park. He also received the order of the Legion of Honour, a pension, and other distinctions, and it was at the public expense that his *Journal d'un Voyage à Temboctou et Jenné dans l'Afrique Centrale, &c.*, was published in 1830.

CAIN, the eldest son of Adam and Eve according to the narrative of the Jehovist (Gen. iv.) Various derivations of the name have been suggested, the most probable being from קָנָה, "to obtain," the word used in Gen. iv. 1: "Eve bare Cain, and said, I have gotten a man from the Lord." According to the Biblical narrative (Gen. iv.) Cain was a tiller of the ground, while his younger brother, Abel, was a keeper of sheep. Enraged at the acceptance of Abel's offering by the Lord, and the rejection of his own, he slew his brother in the field. For this a curse was pronounced upon him, and he was condemned to be a "fugitive and a vagabond" on the earth, a mark being set upon him "lest any finding him should kill him." He took up his abode in the land of Nod, on the east of Eden, where he built a city, which he named after his son Enoch. The narrative presents a number of difficulties, which commentators have sought to solve with more ingenuity than success. On the reason for the preference of Abel's offering to Cain's some light is thrown by the references in the New Testament (Heb. xi. 4; 1 John iii. 12). The phrase "the Lord set a mark upon Cain" is perhaps more accurately rendered "the Lord gave a sign to Cain," and has been variously explained as referring to some pledge of safety given to Cain personally, or to some sign of warning and prohibition to mankind in general. There is an apparent contradiction between the condemnation of Cain to lead a nomadic life (ver. 12) and his subsequent settlement in a city, which it has been sought to reconcile by making the doom refer to the natural restlessness of the criminal and estrangement from the Adamic home. The endeavours that have been made to fix the precise locality of the land of Nod are based upon mere conjecture. The implied existence of a considerable population on the earth (ver. 14) furnishes another difficulty, of which no explanation that has been offered seems completely satisfactory. The parallelism between the list of Cain's descendants (Gen. iv. 18) and the list of the descendants of Seth (Gen. v.) has led several critics to identify the two, though it is denied by others that the mere similarity of the names gives any reasonable ground for doing so.

A Gnostic sect of the 2d century were known by the name of Cainites. They are first mentioned by Irenæus, who connects them with the Valentinians. They believed that Cain derived his existence from the superior power, and Abel from the inferior power, and that in this respect he was the first of a line which included Esau, Korah, the Sodomites, and Judas Iscariot.

CAIRN (in Welsh, *Carne*), a heap of stones piled up in a conical form. In modern times cairns are often erected as landmarks. In ancient times they were erected as sepulchral monuments or tribal and family cemeteries;

The *Duan Eireanach*, an ancient Irish poem, describes the erection of a family cairn; and the *Senchus Mor*, a collection of Irish laws ascribed to the 5th century, prescribes a fine of three three-year-old heifers "for not erecting the tomb of thy chief." Meetings of the tribes were held at them, and the inauguration of a new chief took place on the cairn of one of his predecessors. It is mentioned in the *Annals of the Four Masters* that, in 1225, the O'Connor was inaugurated on the cairn of Fraech, the son of Fiodhach, of the red hair. In mediæval times cairns are often referred to as boundary marks, though probably not originally raised for that purpose. In a charter by King Alexander II. (1221), granting the lands of Burgyn to the monks of Kinloss, the boundary is described as passing "from the great oak in Malevin as far as the *Rune Pictorum*," which is explained as "the Carne of the Pecht's fieldis." In Highland districts small cairns used to be erected, even in recent times, at places where the coffin of a distinguished person was "rested" on its way to the churchyard. Memorial cairns are still occasionally erected, as, for instance, the cairn raised in memory of the Prince Consort at Balmoral, and "Maule's Cairn," in Glenesk, erected by the earl of Dalhousie in 1866, in memory of himself and certain friends specified by name in the inscription placed upon it. See BARROWS.

CAIRNES, JOHN ELLIOTT, a distinguished political economist, was born at Drogheda in 1824, and died on the 8th July 1875. After leaving school he spent some years in the counting-house of his father, who was an extensive brewer. His tastes, however, lay altogether in the direction of study, and he was permitted to enter Trinity College, Dublin. He took the degree of B.A. in 1848, and six years later commenced as M.A. After passing through the curriculum of arts he engaged in the study of law and was called to the Irish bar. But he does not appear to have felt any very strong inclination for the legal profession, and during some years he occupied himself to a large extent with contributions to the daily press, treating of the social and economical questions that affected Ireland. The subject to which at this time he devoted most attention was political economy, which he studied with great thoroughness and care. While residing in Dublin he made the acquaintance of Archbishop Whately, who conceived a very high respect for his character and abilities. In 1856 a vacancy occurred in the chair of Political Economy at Dublin founded by Whately, and Cairnes received the appointment. In accordance with the regulations of the foundation, the lectures of his first year's course were published. The book appeared in 1857, with the title *Character and Logical Method of Political Economy*, and did not, perhaps, receive so much attention as it deserved. It follows up and expands J. S. Mill's treatment in the *Essays on some Unsettled Questions in Political Economy*, and forms a most admirable introduction to the study of economics as a science. In it the author's peculiar powers of thought and expression are displayed to the best advantage. Logical exactness, precision of language, and firm grasp of the true nature of economic facts, are the qualities characteristic of this as of all his other works. If the book had done nothing more, it would still have conferred inestimable benefit on political economists by its clear exposition of the true nature and meaning of the ambiguous term law. To the view of the province and method of political economy expounded in this early work the author always remained true, and several of his later essays, such as those on *Political Economy and Land*, *Political Economy and Laissez-Faire*, are but reiterations of the same doctrine.

His next contribution to economical science was a series of articles on the gold question, published partly in *Fraser's Magazine*, in which the probable consequences of the increased supply of gold attendant on the Australian and Californian gold discoveries are analyzed with great skill and ability. The general conclusions arrived at in these papers with regard to the effects of the depreciation of gold—that finished manufactures would be on the average least altered in price; that raw produce, particularly the portion derived from the animal kingdom, would be most seriously affected; and that, on the whole, the section of the population most nearly concerned in the movement would be the class of labourers or artisans—are highly interesting, and have been confirmed to a remarkable extent by recent statistical researches. The further inferences drawn as to the international results likely to follow on the introduction into the several currencies of so large a mass of gold have not been borne out to the same extent. The facts were too complex to admit of accurate prediction. The articles attracted much attention at the time, and were highly commended by the most competent judges. A critical article on M. Chevalier's work *On the Probable Fall in the Value of Gold*, which appeared in the *Edinburgh Review* for July 1860, may be regarded as the sequel to these papers.

In 1861 Cairnes was appointed to the professorship of political economy and jurisprudence in Queen's College, Galway, and in the following year he published his admirable work *The Slave Power*, one of the finest specimens of applied economical philosophy. The inherent disadvantages of the employment of slave labour are exposed with great fulness and ability, and the conclusions arrived at have taken their place among the recognized doctrines of political economy. To a very large extent the opinions expressed by Cairnes as to the probable issue of the war in America were verified by the actual course of events.

During the remainder of his residence at Galway Professor Cairnes published nothing beyond some fragments and pamphlets, mainly upon Irish questions in which he was deeply interested. The most valuable of these papers are the series devoted to the consideration of university education in Ireland. His health, at no time very good, was still further weakened in 1865 by a fall from his horse, which inflicted severe injury on one of his legs. He was ever afterwards incapacitated from active exertion, and was constantly liable to have his work interfered with by attacks of illness. In 1866 he was appointed professor of political economy in University College, London. He was compelled to spend the session 1868–69 in Italy, but on his return continued to lecture till 1872. During his last session he conducted a mixed class, ladies being admitted to his lectures. His health soon rendered it impossible for him to discharge his public duties; he resigned his post in 1872, and retired with the honorary title of Emeritus Professor of Political Economy. In 1873 his own university conferred on him the degree of LL.D.

The last years of his life were spent in the collection and publication of some scattered papers contributed to various reviews and magazines, and in the preparation of his most extensive and important work. The *Political Essays*, published in 1873, comprise all the papers relating to Ireland and its university system, together with some other articles of a somewhat similar nature. The *Essays in Political Economy, Theoretical and Applied*, which appeared in the same year, contain the essays towards a solution of the gold question, brought up to date and tested by comparison with statistics of prices. Among the other articles in the volume the more important are the criticisms on Bastiat and Comte, and the Essays on *Political Economy and Land*, and on *Political Economy and Laissez-Faire*, which have been referred to above. In 1874 appeared his largest work, *Some Leading Principles of Political Economy, newly Expounded*, which is beyond doubt a

worthy successor to the great treatises of Smith, Malthus, Ricardo, and Mill. It does not expound a completed system of political economy; many important doctrines are left untouched; and in general the treatment of problems is not such as would be suited for a systematic manual. The work is essentially a commentary on some of the principal doctrines of the English school of economists, such as value, cost of production, wages, labour and capital, and international values, and is replete with keen criticism and lucid illustration. While in fundamental harmony with Mill, especially as regards the general conception of the science, Cairnes differs from him to a greater or less extent on nearly all the cardinal doctrines, subjects his opinions to a searching examination, and generally succeeds in giving to the truth that is common to both a firmer basis and a more precise statement. The last labour to which he devoted himself was a republication of his first work on the *Logical Method of Political Economy*, which had long been out of print. The second edition appeared in April, a few months before the author's untimely death.

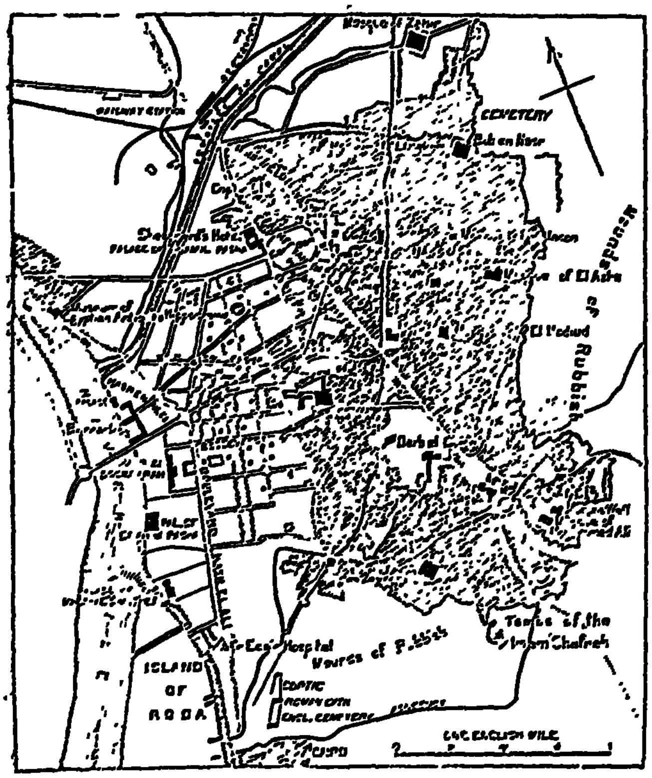
Taken as a whole the works of Cairnes form the most important contribution to economical science made by the English school since the publication of J. S. Mill's *Principles*. As has been already pointed out, they possess especial value by reason of the writer's firm grasp of the nature, method, and limits of the science he is engaged in expounding. It is not possible to indicate more than generally the special advances in economic doctrine effected by him, but the following points may be noted as establishing for him a claim to a place alongside of Ricardo and Mill:—(1.) His exposition of the province and method of political economy. He never suffers it to be forgotten that political economy is a *science*, and consequently that its results are entirely neutral with respect to social facts or systems. It has simply to trace the necessary connections among the phenomena of wealth, and dictates no rules for practice. Further, he is distinctly opposed both to those who would treat political economy as an integral part of social philosophy, and to those who have attempted to express economic facts in quantitative formulæ, and to make economy a branch of applied mathematics. According to him political economy is a mixed science, its field being partly mental, partly physical. It may be called a positive science, because its premises are facts, but it is hypothetical in so far as the laws it lays down are only approximately true, *i.e.*, are only valid in the absence of counteracting agencies. From this view of the nature of the science, it follows at once that the method to be pursued must be that called by Mill the Physical or Concrete Deductive, which starts from certain known causes, investigates their consequences, and verifies or tests the result by comparison with facts of experience. It may, perhaps, be thought that Cairnes gives too little attention to the effects of the organism of society on economic facts, and that he is disposed to overlook what have recently been called by Mr Bagehot the postulates of political economy. (2.) His analysis of cost of production in its relation to value. According to Mill, the universal elements in cost of production are the wages of labour and the profits of capital. To this theory Cairnes objects that wages, being *remuneration*, can in no sense be considered as *cost*, and could only have come to be regarded as cost in consequence of the whole problem being treated from the point of view of the capitalist, to whom, no doubt, the wages paid represent cost. The real elements of cost of production he looks upon as labour, abstinence, and risk, the second of these falling mainly, though not necessarily, upon the capitalist. In this analysis he to a considerable extent follows and improves upon Senior, who had previously defined cost of production as the sum of the labour and abstinence necessary to production. (3.) His exposition of the natural or social limit to free competition, and of its bearing on the theory of value. He points out that in any organized society there can hardly be the ready transference of capital from one employment to another, which is the indispensable condition of free competition; while class distinctions render it impossible for labour to transfer itself readily to new occupations. Society may thus be regarded as consisting of a series of non-competing industrial groups, with free competition among the members of any one group or class. Now the only condition under which cost of production will regulate value is perfect competition. It follows that the normal value of commodities—the value which gives to the producers the average and usual remuneration—will depend upon cost of production only when the exchange is confined to the members of one class, among whom there is free competition. In exchange between classes, or non-competing industrial groups, the normal value is simply a case of international value, and depends upon reciprocal demand, that is to say, is such as will satisfy the equation of demand. This theory is a substantial contribution to economical science, and throws great light upon the general problem of value. At the same time, it may be thought that Cairnes has overlooked a point brought forward prominently by Senior, who also had called attention to the bearing of competition on the relation between cost of production and value. The cost to the producer fixes the limit below which the price cannot fall without the supply being affected; but it is the desire of the consumer—*i.e.*, what he is willing to give up rather than be compelled to produce the commodity for himself—that fixes the maximum value of the article. To treat the whole problem of natural or normal value from the point of view of the producer is to give but a one-sided theory of the facts. (4.) His defence of the wages fund doctrine. This doctrine, expounded by Mill in his *Principles*, has not been universally accepted even by British economists, and has recently been assailed with great vigour by Thornton and F. D. Longe. In consequence of these attacks it has been relinquished by Mill, but Cairnes still undertakes to defend it. He certainly succeeds in removing from the theory much that has tended to obscure its real meaning, and in placing it in its very best aspect. He has also shown the sense in which, when treating the problem of wages, we must refer to some fund devoted to the payment of wages, and has pointed out the conditions under which the wages fund may increase or decrease. But he has not, it seems to us, been successful in showing that the theory is fruitful, or gives any satisfactory explanation of the many complicated questions connected with the varying rates of wages.

These points, of course, do not comprehend all or nearly all that Cairnes has handled in his peculiarly fresh and attractive manner. *The Leading Principles*, for instance, contain admirable discussions on trades unions and protection, together with a clear analysis of the difficult theory of international trade and value, in which there is much that is both novel and valuable, while numerous minor topics are treated throughout the volume. The *Logical Method* contains the best exposition and defence known to us of Ricardo's theory of rent; and the *Essays* contain what is probably the most complete and successful criticism of Bastiat's economic doctrines. (R. AD.)

CAIRNGORM, or CAIRNGORUM, a name popularly applied to a wine-yellow or brown variety of rock crystal found, among other localities, on the Grampian Mountains in the south-east of Banffshire, Scotland, the central peak being called Cairngorm. The colour of the crystals, which is due to a minute proportion of iron oxide, varies, passing through those above noted as belonging properly to cairngorms, into a dull grey, smoky quartz, and to a black

variety, called morion. The same stone is found in commerce passing under the names of false topaz, Brazilian topaz, occidental topaz, and cinnamon stone (*pierre de cannelle* of the French). It is found in many parts of the world, Brazil producing the finest deep brown varieties; but fine stones also come from India, Bohemia, Mexico, and Pennsylvania. It is also found at the Carnbrae Mines, in Cornwall. In the cairngorm district masses weighing as much as 25 lb have been obtained, and an Edinburgh lapidary cut nearly £400 worth of ornamental stones out of a single crystal. The cairngorm is chiefly used for Scotch jewellery, the mounting of gold and silver plaid-brooches, setting in the lids of snuff-mulls, the handles of dirks, &c., and the ornamentation of other articles connected with the Highland costume. The stones are most effectively set by covering the undersets entirely with oblong facets arranged in regular rows, surrounding the table with triangular facets and keeping the stone as thick as possible. By this means great brilliancy combined with depth of colour, is secured

CAIRO (in Arabic, Misr-al-Kahira, or, as the lower classes of the population call it, simply Masr), the modern capital of Egypt, occupies the natural centre of the country,



Ground-Plan of Cairo.

1. Karameydan (Place Mehemet Ali)

3. Post-Office.
4. French Theatre
5. Opera House.
6. English and German Churches.

being situated on the east bank of the Nile, 12 miles above the apex of its delta, 150 miles by rail from Alexandria, and 80 west from Suez, in 30° 2′ 4″ N. lat. and 31° 15′ 26″ E. long. It is built partly on the plain and partly on the lower slopes of the rocky range of Mokattem, on a spur of which stands the citadel, 250 feet above the level of the town. The prospect from the ramparts of this fortress is one of great magnificence and beauty. Below lies the city with its strongly-built walls and lofty towers, its gardens and squares, its palaces, and its mosques, in all the beauty of their delicately-carved domes and minarets covered with fantastic tracery, the port of Bulak, the gardens and palace of Shubra, the broad river studded with islands, the valley of the Nile dotted with groups of trees, with the pyramids on the north horizon, the fields, gardens, and villas on the west, and on the east the barren cliffs, backed by an ocean of sand.

As far as the portion within the walls is concerned, Cairo occupies a site of about seven miles in circumference; but during the reign of the khedive (properly *hidiv*), who was born in the city in 1830, it has extended, especially towards the river, so as to have a circuit of at least 8 or 9 miles. Its improvement has kept pace with its extension, and it can no longer be altogether described as little better than a labyrinth of tortuous lanes, narrow, unpaved, and continually swept with clouds of dust blown from huge mounds of rubbish outside the walls. New streets have been cut through the more crowded districts; and the Ezbekeeyah, the principal square of the city, which was formerly allowed to lie waste, has been transformed into public gardens with a lake in the centre, while houses and shops of considerable pretensions have sprung up in the neighbourhood. Most important of the new streets is the Boulevard Mehemet Ali, which traverses the city in an almost northerly direction from the Citadel to the Ezbekeeyah. Between the western side of the older city and the river most of the ground has been laid out in building lots, and in various parts, as particularly in the direction of Bulak, it is already covered with regular rows of houses, and forms the district of Ismaileeyah. Bulak, in fact, is not so much a distinct town as a mere suburb of the larger city. Gas has been laid down in all the principal streets, and water is supplied by a company to the houses of all those who comply with the necessary regulations. In spite of all these innovations, however, the city largely retains its Oriental character, and in a hundred of its narrow streets it is easy to forget that any change at all has taken place.

The most of the houses of the poorer classes consist of miserable mud hovels, with filthy courts, dilapidated windows, and tattered awnings. In marked contrast to these are the houses of the wealthier citizens, built generally in a style of elaborate arabesque, the windows shaded with projecting cornices of graceful woodwork, and ornamented with stained glass. A winding passage leads through the ornamented doorway into the court, in the centre of which is a fountain shaded with palm-trees. The principal apartment is generally paved with marble; in the centre a decorated lantern is suspended over a fountain, whilst round the sides are richly inlaid cabinets and windows of stained glass; and in a recess is the *divan*, a low, narrow cushioned seat running round the walls. The basement story is generally built of the soft calcareous stone of the neighbouring hills, and the upper story, which contains the harem, of painted brick.

The town is walled off into quarters, deriving their names from the character or condition of their occupants, and is intersected in its whole breadth by a canal which conveys the waters of the Nile from Old Cairo to the different parts of the city. The citadel or El-Kalah was built by Saladin about 1166, but it has since undergone frequent alteration, and now contains a palace erected by Mehemet Ali, and a mosque of Oriental alabaster founded by the same pasha on the site of "Joseph's Hall." In the centre is a well called Joseph's Well, sunk in the solid rock to the level of the Nile. Next to the citadel in importance are the mosques, 400 in number, including, however, many that are falling to ruins. The most magnificent is the Mosque of Sultan Hasan, standing in the immediate vicinity of the citadel. It dates from 1357, and is celebrated for the grandeur of its porch and cornice, and the delicate honeycomb tracery which adorns them. Besides it there is the Mosque of Tulun (founded 879 A.D.), exhibiting very ancient specimens of the pointed arch; the Mosque of Sultan el

Hakem, the fanatical patron of the Druzes, founded in 1003, the Mosque Al Azhar ("The Splendid"), which is principally famous as the seat of a Mahometan university, in which gratuitous instruction is given in the Koran; and the Mosque of Sultan Kalaoon, attached by its founder to the great Mooristan or madhouse, which he established in 1287. The Mooristan is no longer used for its original purpose, having been superseded by an asylum at Bulak. There is also a large general hospital situated between Bulak and Old Cairo, under the charge of native doctors.

On the east of the city are the splendid structures erroneously known to Europeans as the tombs of the caliphs; they really belong to the Circassian or Borgite Mamelukes, a race extinguished by Mehemet Ali. Their lofty gilt domes and fanciful network of arabesque tracery are falling to ruins, and the mosques attached to them are the haunts of a few solitary sheikhs, and of hordes of Arab beggars.

Among the buildings which owe their existence to modern European influence, the Italian opera, the French theatre, and the hippodrome may be mentioned. In Bulak is situated the Government printing-press, established by Mehemet Ali, from which numerous Oriental works and translations of French originals are issued from time to time; and in a building by the river side is accommodated the unrivalled collection of Egyptian antiquities made by M. Mariette for the khedive. The manuscripts which were formerly scattered among the various mosques and other institutions were recently collected to form a public library in the palace of the Darb Algamâmîz or Sycamore Street. The catalogue already occupies 333 pages, and the collection is especially rich in copies of the Koran and works of grammatical exegesis. In 1875 a geographical society was founded by the khedive for purposes of African discovery. A few periodicals are published in the city, but in this respect Cairo is much behind Alexandria. The scheme of public instruction is mainly that which was organized by Mehemet Ali, and embraces primary, preparatory, and special schools. In 1872 there were 1025 students and 141 teachers in the Government colleges, and the national schools were attended by 4721 pupils, while in the Mosque Al Azhar 6774 were enrolled. The higher scholastic institutions comprise a commercial and a juridical school at the Darb Algamâmîz, a school of arts and industry at Bulak, and military schools at the Abbasseeyah. There are several Christian churches and missionary stations in the city, and most of these maintain some educational machinery, so that there are Armenian, Greek, Coptic, Roman Catholic, and Protestant schools. Of special interest to Englishmen is Miss Whately's institution in the Abbasseeyah road.

The commerce of Cairo is of considerable extent and variety, but consists mainly in the transit of goods. Gum, ivory, hides, and ostrich feathers from the interior, cotton and sugar from Upper Egypt, indigo and shawls from India and Persia, sheep and tobacco from Asiatic Turkey, and European manufactures, such as machinery, hardware, cutlery, glass, and woollen goods, are the more important articles. The traffic in slaves, which was at one time so striking a feature of the place, is still carried on to a certain extent. In Bulak are several factories founded by Mehemet Ali for spinning, weaving, and printing cotton, and a paper-mill established by the khedive in 1870 at a cost of about £80,000. Various kinds of paper are manufactured, and especially a fine quality for use in the Government offices. In the island of Rhoda, or Roudah, there is a sugar-refinery of considerable extent, founded in 1859, and principally managed by Englishmen. Silk goods, saltpetre, gunpowder, leather, &c., are also manufactured. An iron bridge has been erected over the Nile between the Kasr el Dubbara on the right bank and Gezirah on the left; and new carriage roads, bordered by acacias and sycamore trees, have been constructed to Heliopolis and the pyramids of Gizeh respectively. The terminus of the railway lines of the delta and isthmus is situated to the north of the city, but the Upper Egypt line stops short on the left bank of the river at Embabah opposite Bulak, and the trains have to be taken across by a ferry.

From the central situation of Cairo, and its proximity to the hot sandy deserts, the temperature is much higher there than near the coast; but the diseases which infest it, such as the plague, ophthalmia, and malignant fevers, seem to originate in its "stifled filth," and other local causes, which advancing civilization will greatly remove, rather than in the unhealthiness of its situation. Its death-rate is greater than that of any European capital, but this is partly to be accounted for by the fact that numbers of natives come to the city in order that their last hours may be spent within its walls. The greatest mortality is during winter, and a larger proportion of deaths is caused by consumption than by any other disease. The average temperature throughout the year is 71°·16 Fahr.; but the mean of the separate months varies from 54° in January to 86° in August. The temperature by night is sometimes 40° below the highest point reached during the day, more especially in March and April, when the south and south-west winds prevail, and the thermometer frequently rises to upwards of 100° in the shade. In 1871 the number of rainy days was only 9, and the total duration of the fall was 9 hours 8 minutes.

The population of Cairo is of a very mingled description, and presents a very picturesque and interesting appearance. About the beginning of this century it was estimated to amount to about 200,000, which was supposed to comprise 121,000 Mahometans, 60,000 Copts, 4000 Jews, and a number of Franks, Greeks, and Armenians. It now numbers about 350,000, which may be distributed in the following proportions:—285,000 natives, 25,000 Nubians and natives of the Soudan, 10,000 Turks, 30,000 Jews and Levantines, and upwards of 19,000 Europeans. The German and English colonies are both pretty numerous, and possess each its own church.

About 2¼ miles S.W. of the citadel, and 1¾ from the S.W. angle of the city, lies the town of Misr-al-'Atikah, or Old Cairo, situated on the Nile near the mouth of the canal which now flows through Cairo, and opposite to the famous Nilometer at the south end of the island of Raudah. It occupies the site of the ancient Roman city or fortress of Babylon, of whose origin various stories of apparently little value are told by Diodorus and others. The place appears in Ptolemy's *Tables*, and Strabo mentions that it was the headquarters of one of the three Roman legions that garrisoned Egypt. Roman masonry survives as part of a convent enclosure, which is known by the names Kasr-es-Shama ("Palace of the Candle") and Dair-en-Nasarah ("Convent of Christians").

The name Babylon of Egypt, or Babylon simply, is frequently employed in mediæval writings as synonymous with Cairo, or as denoting the successive Mahometan dynasties of Egypt. This use may have been influenced by the association of the other Babylon, as represented by Baghdad, with the power of Islam: but at the same time it was a real survival from the ancient name; for Babylon on the Nile is mentioned by Gregory of Tours (circa [illegible] A.D.), in connection with the *Granaries of Joseph*—i.e. the Pyramids. Here Amru the famous conqueror of Egypt for the Caliph Omar (638) founded a city to which was given the name of Fostât, it is said from Amru's skin tent (so called in Arabic). It continued to be the capital of Egypt for upwards of 330 years. In 973 it was superseded by a new city founded shortly before by Jauher (Gowher), captain of the first Fatimite caliph, Al [illegible], whose army had conquered Egypt in 969. It is said that the new city was originally the camp of Jauhar whilst besieging Fostât, which gradually grew into a town, and got the name of Al [illegible] ("Victrix"), whence our Cairo. In 1176 the city was attacked by [illegible] the Franks; and shortly afterwards it was fortified by [illegible]. It was the capital of the Turkish province of Egypt from 1517 to 1798, when it was captured by the French, who were driven out in 1801 by the Turkish and English forces. Mehemet Ali secured his position by the massacre of the Mamelukes in the citadel in 1811, and laid the basis of the independence of Egypt.

CAIRO, a city of the United States, capital of Alexander county, Illinois, situated between the Ohio and Mississippi, at the extreme south of the State, 147 miles from St Louis by rail. On account of its low situation it has often suffered from inundations, especially in the summer of 1858, when it was nearly destroyed, but it is now better protected by embankments. Steamers ply between the city and the Ohio and Mississippi ports, and it is an important depot for the produce of the neighbouring States. Large warehouses have recently been built, and both city and trade are steadily increasing. Cairo possesses a fine custom-house and county buildings. Population in 1860, 2188, and in 1870, 6267.

CAISSON, in engineering work, is a chamber of iron or wood which is used in the construction of subaqueous foundations,—such as those required for the piers of bridges, &c. Its object is the same as that of a coffer-dam, viz., to allow the work to be carried on below the water-level,—but it is used in places where either the water or the permeable soil is too deep to allow a dam to be erected. In cases where the bridge piers are hollow cylinders of iron, they not unfrequently form their own caissons,—their own weight, or that of ballast placed upon them, forcing their lower edges into the ground. The material left within them is dredged up or excavated as they descend. Where, however, the soil is not so soft, or is mixed with stones, this self-lowering becomes impossible. The lower part of the caisson is then commonly formed into an air chamber, open at the bottom, and resting upon the bed of the river Air is pumped into this at a pressure corresponding to its depth below the surface of the water, and the excavation is carried on by men working in the compressed air as in a large diving-bell. In some cases the masonry of the pier is built within the caisson on the top of the chamber as it descends, the chamber itself being eventually filled up with masonry or concrete, and left to form the permanent base of the structure; in others the caisson is lowered (as the excavation goes on) by weights; and when the required depth has been reached, the masonry is commenced within the air-chamber, and the whole caisson raised again as the building proceeds. Probably the largest caissons ever used are those of the East River Suspension Bridge (a structure still unfinished) at New York, of which one was 172 feet long by 102 feet wide. See BRIDGES. For military caissons see FORTIFICATION.

CAITHNESS, the most northern county of the Scottish mainland, bounded W. and S. by Sutherlandshire, and E. and N. by the Northern Ocean, is situated between 58° 8′ and 58° 40′ N. lat., 3° 0′ and 3° 55′ W. long., and has an extreme length of 53 miles, an extreme breadth of 33, a coast line of 105 miles, and an area of 455,708 acres or 712 square miles. The form of Caithness resembles an irregular triangle, having as its greatest side the line of coast on the S.E., stretching from the Ord of Caithness to Duncansby Head. The surface of the county generally is flat and tame, consisting for the most part of barren moors, and being almost entirely destitute of trees. It presents a gradual slope from the north and east upwards to the ridge of hills on the west and south, which separates it from Sutherlandshire, and on the southern boundary, where it is bifurcated, attains considerable elevation. The one branch, called the Maiden Paps, contains the peak of Morven, 2334 above the level of the sea; the other, continuing in the line of the main ridge, juts into the sea, and terminates in the huge granitic precipice of the Ord. In the centre of the county, hemmed in by the hills on the western boundary, the ridge of the Maiden Paps, and the sea, is a large undulating plain comprising nearly four-fifths of the whole extent. On its southern side it is broken up by several detached hills, and in the interior contains a considerable number of small lakes. The most depressed part of the county lies in the peninsula formed in the north-east corner by the indentation of Dunnet Bay and Sinclair Bay. The more elevated portion presents a light sandy soil, which admits of considerable cultivation, but the low grounds are covered with extensive morasses, producing only heath and rough grass.

The geological formation consists chiefly of sandstone, sandstone flag, and occasionally limestone; but granite and gneiss are also found in the west. On the east Caithness presents a precipitous coast, with scarcely a creek in which a vessel, even of small size, can find shelter. On the northern coast, where the Pentland Firth separates it from the Orkney islands, stand at the distance of 13 miles from each other the two bold headlands of Duncansby Head on the north-east and Dunnet Head on the north-west. The latter, the most northern point of Scotland, is situated in 58° 40′ N. lat. and 3° 21′ W. long., and is crowned by a lighthouse, with a fixed light, built on the rock 346 feet above the level of the sea; while the former is marked by the white steeple of Cannisby on the west. The navigation of the Pentland Firth is attended with considerable danger, from the strength and eddies of the current. Off the island of Stroma, which is separated from the mainland by a strait three miles broad, is a small vortex called the Swalchie; while nearer the shore are the "Merry Men of Mey," a group of breakers caused by eddies between projecting headlands. On the east coast, in addition to the harbour of Wick, erected in 1831, at a cost of above £40,000, and since improved at further expense, there is a small harbour at Sarclett and another at Staxigoe, a small pier at Clyth and another at Lybster. On the northern coast Scrabster roads in Thurso Bay afford tolerably good anchorage, while at Thurso and Sandside Bay are commodious harbours for larger vessels.

The climate of Caithness is variable, but not unhealthy; and though the winter storms fall with great severity on the unsheltered coast, yet from its proximity to a large expanse of sea the cold is not intense and snow seldom lies many days continuously. In winter and spring the northern shore is subject to frequent and disastrous gales from the N. and N.W. The waters of Forss, Thurso, and Wick, are the principal streams which traverse the county, but none of them are of any particular importance. The largest lochs are those of Watten and Cathel; there are numerous small ones well stocked with trout.

A great change has been effected in the agricultural position of Caithness, chiefly by the late James Traill, Esq. of Ratter. The farms along the coast are still mostly in the hands of small farmers, who cultivate the soil only during the intervals of the fishing-season; but inland, in the more elevated districts, and along the banks of the principal streams, the land is let out into large farms, with leases long enough to encourage the holder to improve the soil and practise a rotation of crops. The average extent of land held by each occupier, in 1874, was 39 acres, much larger than the average in Sutherlandshire, which only amounted to 10 acres in the same year. In the pasturage ground, black cattle and sheep, chiefly of the Leicester and Cheviot breeds, are reared for the southern markets; and, independently of the weekly corn-markets at Thurso and Wick, the rapidity of communication with the south is opening up a valuable market for the produce of the dairy and farmyard.

The principal crops raised are oats, beans, potatoes, and turnips; wheat can be grown only where draining has been carried to considerable perfection. In 1874 there were only 87 acres in wheat, 1895 in barley, 70 in rye, and 27 in peas; while oats occupied 33,071 acres, turnips 14,045, and potatoes 2190. In the same year there were 21,567

acres in permanent pasture, and 6222 in temporary grass, while only 440 were covered with wood. The number of cattle of all kinds in the county was 22,616, sheep 108,829, horses 4969, and pigs 1789. But the great source of profit to the inhabitants is to be found in the fisheries of cod, ling, lobsters, and herring, which abound all around the coast. The most important is the herring-fishery, though it has considerably lessened in value during the last twenty or thirty years. Beginning about the end of July the season lasts for about six weeks, the centre of operations being at Wick and the surrounding districts. The number of fishermen employed in 1874 was 4304; and the value of boats, nets, lines, &c., for the same year, was estimated at £112,270. Besides those more immediately engaged in manning the boats, the fisheries give employment to a large number of coopers, curers, packers, and others. The salmon-fisheries on the coast and at the mouths of rivers were formerly very productive, and are still let at high prices. At intervals along the coast are valuable quarries of freestone and slate, and of excellent flag for pavements; but the county is far from rich in other minerals. Slight traces of lead and iron have been found in the mountainous districts; and indications of coal, or rather of bituminous shale, have been noticed at Cannisby. The only article of manufacture is woollen cloth. The Highland Railway, opened in 1873, enters the county from Sutherlandshire, and curves through the centre to Wick, passing Altnabreac, Scotscalder, Halkirk, Georgemas, Bower, Watten, and Bilbster; while a branch line runs from the Georgemas junction to Thurso.

The early history of Caithness may, to some extent, be traced in the various character of the remains and the diversity of its local nomenclature. Picts' houses, Norwegian names, and Danish mounds attest that the Celts were successively displaced by these different tribes; and the number and strength of its fortified keeps leave us to infer that its annals present the usual record of feuds, assaults, and reprisals. Circles of erect stones, as at Steinster Loch and Bower, and the ruins of Romanist chapels and places of pilgrimage in almost every district, illustrate the changes which have come over its ecclesiastical condition. The most important remains are those of Bucholie Castle, Girnigo Castle, and the tower of Keiss; and on the S.E. coast the castles of Clyth, Swiney, Forss, Latheron, Knockinnan, Berridale, Achastle, and Dunbeath,—of which the last is romantically situated on one of the detached pillars of sandstone rock that are frequent along the Caithness coast. About six miles from Thurso stand the ruins of Braal Castle, the residence of the ancient bishops of Caithness, and on the shores of the Pentland is situated the mythical site of John o' Groats' House. The total number of landowners in 1872–3 was 1030,—among the most important being the duke of Portland, with 81,605 acres; Sir John Sinclair of Tollemache, with 78,053; Mrs Thomson Sinclair of Fenswick, with 57,757; Sir Robert Anstruther of Balcaskie in Fife, with 36,597; and the earl of Caithness, with 14,460.

Caithness is divided into ten civil and twelve *quoad sacra* parishes, and contains twelve churches and two chapels of ease belonging to the Establishment (in four of which there is service in Gaelic); seventeen belonging to the Free Church (in seven of which there is service in Gaelic); one United Presbyterian, and one Roman Catholic at Wick.

The county returns one member to the imperial parliament. The parliamentary constituency in 1875–76 was 1172. The principal towns are Wick and Thurso; the most important villages are Broadhaven, Castletown, Louisburgh, Sarclett, and Staxigoe. The population in 1831 was 34,529; in 1841, 36,343; in 1851, 38,709; and in 1871, 39,992. In the last year the males numbered 18,937, and the females 21,055; and there were in the county at the same date 7474 inhabited houses, 203 vacant, and 431 building.

CAIUS, KAYE, or KEYE, Dr JOHN (1510–1573), the founder of Caius College in Cambridge, was born at Norwich in 1510. He was admitted while very young a student at Gonville Hall, Cambridge. From his exercises performed there it seems probable that he intended to prosecute the study of divinity. He visited Italy, where he studied under the celebrated Montanus at Padua; and in 1541 he took his degree in physic at Bologna. In 1543 he visited several parts of Italy, Germany, and France; and returning to England, he began to practise first at Cambridge, then at Shrewsbury, and afterwards at Norwich. He removed to London in 1547, and was admitted fellow of the College of Physicians, of which he was for many years president. In 1557, being then physician to Queen Mary, he obtained a licence to advance Gonville Hall into a college, and he endowed it with several considerable estates, adding an entire new square at the expense of £1834. Of this college he accepted the mastership, which he held till within a short period of his death. He was physician to Edward VI., Queen Mary, and Queen Elizabeth. Towards the end of his life he retired to his own college at Cambridge, where having resigned the mastership to Dr Leggie of Norwich, he spent the remainder of his life as a fellow commoner. He died in July 1573, and was buried in the college chapel. Dr Caius was a learned, active, and benevolent man. In 1557 he erected a monument in St Paul's to the memory of Linacre. In 1563 he obtained a grant for the College of Physicians to take the bodies of two malefactors annually for dissection; and he was the inventor of the *insignia* which distinguish the president from the rest of the fellows.

His works are—1. *Annals of the College from* 1555 *to* 1572. 2. Translation of several of Galen's works, printed at different times abroad. 3. *Hippocrates de Medicamentis*, first discovered and published by Dr Caius; also *De Ratione Victus*, Lov. 1556, 8vo. 4. *De Mendeti Methodo*, Basel, 1554; Lond. 1556, 8vo. 5. *Account of the Sweating Sickness in England*, Lond. 1556, 1721. It is entitled *De Ephemera Britannica*. 6. *History of the University of Cambridge*, Lond. 1568, 8vo; 1574, 4to, in Latin. 7. *De Thermis Britannicis*; but it is doubtful whether this work was ever printed. 8. *Of some Rare Plants and Animals*, Lond. 1570. 9. *De Canibus Britannicis*, 1570, 1729. 10. *De Pronunciatione Græcæ et Latinæ Linguæ*, Lond. 1574. 11. *De Libris propriis*, Lond. 1570. He also wrote numerous other works which were never printed.

CAJAZZO, or CAIAZZO, a town of Italy, in the province of Terra di Lavoro, and district of Piedimonte, situated on a height on the north bank of the Volturno, about 11 miles from Capua. It possesses a fine cathedral, and is defended by a castle of Lombard origin; but is principally interesting for the ruins of the Roman *Calatia*, which are still found in the town and neighbourhood. These consist chiefly of remains of the outer walls, and a cistern, which still affords a good supply of water. Various inscriptions are also extant, and the inhabitants point out a tomb which they maintain to be that of A. Atilius Calatinus. Calatia was originally a Samnite town, and is frequently mentioned in the earlier wars of the Romans. At a later date it became a municipal city of some importance, but makes no appearance in history. The population of the present town is 5892.

CAJEPUT OIL, a volatile oil obtained by distillation from the leaves of *Melaleuca leucadodendron*, and probably other species. The trees yielding the oil are found throughout the Indian Archipelago, the Malay peninsula, and over the hotter parts of the Australian continent; but the greater portion of the oil is procured from Celebes Island. The name Cajeput is derived from the native *Kayu-puti* or white wood. The oil is prepared from leaves

collected in a hot dry day, which are macerated in water, and distilled after fermenting for a night. As imported into Europe it has a greenish colour owing to the presence of a minute proportion of copper, which can be separated, leaving the oil perfectly colourless. This oil is extremely pungent to the taste, and has the odour of a mixture of turpentine and camphor. When dropped in water, it diffuses itself over the surface, and then entirely evaporates. Chemically, the oil consists in large part of the bihydrate of cajputene, from which cajputene having a hyacinthine odour can be obtained by distillation from anhydrous phosphoric acid. Like other volatile oils, the cajeput is a powerful stimulant, and is used medicinally where such medicines are required. Some practitioners have given it a high character as a remedy for cholera; but it does not appear to have any claim as a specific in the treatment of that disease. The dose taken internally as a stimulant, antispasmodic, and diaphoretic, is about five drops. It is used externally as a rubefacient, and is also resorted to occasionally with advantage in toothache. The oil from some species of *Eucalyptus* bears a close resemblance in odour and properties to cajeput.

CAJETAN, CARDINAL (1469–1534), was born at Cajeta in the kingdom of Naples in 1469. His proper name was Thomas de Vio, but he adopted that of Cajetan from his birthplace. He entered the order of the Dominicans at the age of sixteen, was for some time professor of divinity, and in 1508 became general of the order. For his zeal in defending the Papal pretensions, in a work entitled *Of the Power of the Pope*, he obtained the bishopric of Cajeta He was afterwards raised to the archiepiscopal see of Palermo, and in 1517 was made a cardinal by Leo X. The year following he went as legate into Germany, to quiet the commotions raised by Luther against indulgences; but the Reformer, under protection of Frederick elector of Saxony, set him at defiance; for though he obeyed the cardinal's summons in repairing to Augsburg, yet he rendered all his proceedings ineffectual. Cajetan was employed in several other negotiations and transactions, being as able in business as in letters. He died in 1534. He wrote commentaries upon portions of Aristotle, and upon the *Summa* of Aquinas, and made a careful translation of the Old and New Testaments, excepting Solomon's Song, the Prophets, and the Revelation of St John.

CALABAR is a district of somewhat indefinite boundaries, situated on the West Coast of Africa, in the Bight of Biafra, between 4° 20′ and 6° N. lat., and between 6° 30′ and 9° E. long. The name corresponds to no geographical or political unity, but is convenient as provisionally comprehending a stretch of country of considerable commercial importance. The coast line is frequently regarded as extending from the Nun mouth of the Niger, to the neighbourhood of the Cameroon Mountains, and thus includes the estuaries of the Brass River or Tuwon-Toro, the San Nicholas or Kola Toro, the New Calabar, and the Bonny, which are all deltaic branches of the Niger, as well as the San Pedro or Kan Toro, and the important embouchure of the united streams of the Cross River, the Old Calabar, and the Great Qua River. The interior of the country is still unexplored, and the inland boundary is left completely vague. The soil of the whole country, for 150 miles or further from the sea, is purely alluvial; and the surface is literally covered with bush except in the very limited areas under cultivation. Further inland, especially in the direction of the Cameroon Mountains, the elevation increases, the soil becomes more varied and decidedly rocky, and the forest grows clearer of underwood. This higher region is rich in natural productions, furnishing—besides the palm-oil which forms the main article of foreign trade on the coast—ebony, bamboos, sugar, pepper, yams, Indian corn, plantains, and a variety of woods.

Leaving the western portion which belongs to the delta of the Niger for treatment in the article on that river, we will confine our attention here to the district watered by the Old Calabar, the Cross River, and the Qua, which more particularly deserves the name of Calabar. The common estuary of these three rivers enters the ocean about 5° N. lat. and 8° 20′ E. long. It is about 10 or 12 miles wide at its mouth, and maintains nearly the same width for about thirty miles above the bar. At the junction with the Cross River the Old Calabar forms quite a labyrinth of channels and islands, and it is also united with the Qua by a number of creeks.

The exact position of the sources of these rivers has never been ascertained, but, according to native report, that of the Old Calabar is situated in the neighbourhood of Iko, which is not very far beyond Uyanga, the furthest point inland reached by Captain Hopkins and the Rev. Samuel Edgerley in their journey of exploration in 1872. The truth of this report is rendered almost certain by the diminished size of the stream in the vicinity of Uyanga; and it is thus probable that the mountains in which both it and its sister streams take their rise are the Rimsby range, forming a western extension of the Cameroons. The Qua River is comparatively small, and navigation is impeded, at no great distance up, by sand-banks and fallen trees. Further inland its course is also broken by rapids and several cataracts.

The country watered by these rivers is occupied by a great number of separate tribes, such as the Efik, the Ekoi, the Ibami, the Ököyöng, and the Aqua, who are politically independent of each other and speak separate languages. Of these the most important are the Efik, or people of Calabar in the strictest sense of that word, which was originally applied by the Portuguese discoverers to the tribes on the coast at the time of their arrival, when as yet the present inhabitants were unknown in the district. It was not till the early part of the 18th century that the Efik, owing to civil war with their kindred the Ibibio, migrated from the neighbourhood of the Niger to the shores of the Old Calabar, and established themselves at Ikoritungko or Creek Town. In order to get a better share in the European trade at the mouth of the river a body of colonists from this city migrated further down and built Obutöng or Old Town, and shortly afterwards a rival colony established itself at Aqua Akpa or Duke Town.

For a time it seemed as if Creek Town would disappear before its younger competitors, but it was again raised to power by King Eyo Eyo, who defied the interference of his rivals. The only political bond of union between the various towns is the Egbo, a kind of secret society into which admittance is obtained on the payment of a certain fee to each of the existing members. The power of this association is almost unlimited, and is used principally for the benefit of its members. Formerly it was one of the greatest curses of the country, from the barbarous customs mingled with its rites; but it is, under European direction, being turned into a means of promulgating a more civilized code of laws through the various towns, and it forms a kind of constitutional defence against the despotism of individual kings. However unsatisfactory the condition of the country still is, there is no doubt European influence of a beneficial kind is gradually making itself felt. The universal belief in the most terrible kinds of witchcraft is slowly being shaken; the use of the esere or Calabar bean as an ordeal, and for purposes of religious purgation, is becoming much less frequent; the murder of twin children is no longer a national custom; and the massacre of his slaves on the death of a king has been abolished. The present king of Creek Town is at least nominally a Christian; and, according to Consul Livingstone, "hundreds

of decently-dressed natives of both sexes regularly attend divine service" at the mission stations. These number five or six, and are supported by the United Presbyterian Church of Scotland, which began its labours here in 1846.

The predominant language, not only among the people of Calabar proper, but also of the various tribes on both sides of the Cross River, is Efik, which bids fair to be the common commercial speech of the whole district. It is really a modified Ibibio, and presents traces of what is known as alliterative concord, though this is by no means a universal characteristic. It has been reduced to writing by the missionaries, who have employed the ordinary English alphabet. Considerable progress has been made in the formation of an initiatory literature; no fewer than 65 volumes having proceeded from the mission press. Most important of these are the Efik translation of the New Testament by H. Goldie (1862), the translation of the Old Testament by Dr A. Robb (1868), and a Dictionary of the Efik by H. Goldie, published in 1862. Captain James Broom Walker of Duke Town, who has explored various parts of the country, presented several charts to the Royal Geographical Society, which are reproduced in the *United Presbyterian Missionary Record* for 1872 and 1875.

See Hope M. Waddell, *Twenty-nine Years in the West Indies and Central Africa*, 1866; "Details of Explorations of the Old Calabar River," by Captain Becroft in *Journ. Roy. Geogr. Soc.*, 1844; W. Nicholas Thomas in *Proceed. of Roy. Geogr. Soc.* on "The Oil Rivers of West Africa," 1873.

CALABAR BEAN, the seed of a leguminous plant, *Physostigma venenosum*, a native of tropical Africa. The plant has a climbing habit like the scarlet runner, and attains a height of about 50 feet, with a stem an inch or two in thickness. The seed pods, which contain two or three seeds or beans, are 6 or 7 inches in length; and the beans are about the size of an ordinary horse bean but much thicker, with a deep chocolate brown colour. They constitute the E-ser-e or ordeal beans of the negroes of Old Calabar, being administered to persons accused of witchcraft or other crimes. In cases where the poisonous material did its deadly work it was held at once to indicate and rightly to punish guilt; but when it was rejected by the stomach of the accused, innocence was held to be satisfactorily established. A form of duelling with the seeds is also known among the natives, in which the two opponents divide a bean, each eating one-half; that quantity has been known to kill both adversaries. Although thus highly poisonous, the bean has nothing in external aspect, taste, or smell to distinguish it from any harmless leguminous seed, and very disastrous effects have resulted from its being incautiously left in the way of children. The beans were first introduced into England in the year 1840; but the plant was not accurately described till 1861, and its physiological effects were investigated in 1863 by Dr Thomas R. Fraser. In that year an alkaloid was isolated from the seeds to which the name physostigmine was applied; and under the name eserine another alkaloid was prepared from them; but it is not yet quite certain that the two substances are essentially different. Dr Fraser's investigations, which were conducted with an alcoholic extract of the seeds, showed that the active principles exerted a remarkable influence in contracting the pupil of the eye, and in counteracting the influence of atropine. The antagonism of physostigmine and atropine and its relations to many other alkaloids have subsequently been the subject of very numerous investigations. A committee of the British Medical Association under Professor Hughes Bennett found that the antagonism between sulphate of atropine and extract of Calabar bean exists only within narrow limits, so that for practical purposes atropine is useless as an antidote to Calabar bean. The investigation of the same committee into the relations of hydrate of chloral and Calabar bean, however, proves that they are mutually antagonistic, but as the toxic influence of the Calabar bean is very rapid, it is necessary to administer the chloral as soon as possible after the Calabar bean is taken. Calabar bean in the form of powder and extract is used in medical practice. It has been chiefly employed by ophthalmists to produce contraction of the pupil, but it is also used in tetanus, neuralgia, and rheumatic diseases.

CALABOZO, or CALABOSO, a town of Venezuela, formerly capital of the province of Caracas, but now of that of Guarico, is situated 120 miles S.S.W. of the city of Caracas on the left bank of the River Guarico. It lies so low that during the rainy season it is frequently surrounded by the floods; and in the summer it is exposed to extreme heat, the average temperature being 88° Fahr. It is well built, with streets running at right angles, and it has several fine churches, a college, and public schools. Its situation on the main road from Aragua to Apure makes it the seat of a considerable trade; and the surrounding country affords extensive pasture for cattle. There are thermal springs in the neighbourhood. Originally a small Indian village, Calabozo owes its existence as a town to the Compania Guipuzcoana, who made it the seat of one of their mercantile stations in the beginning of the 18th century. In 1820 it was the scene of a battle in which Bolivar and Paez beat the Spanish general Morales. Population in 1873, 5618.

CALABRIA, the name given by the Romans to the peninsula at the south-eastern extremity of Italy, and now given to the peninsula at the south-western extremity. The former district was called by the Greeks Iapygia and Messapia, though these terms were variously used, and sometimes also included all the south-east of Italy, from Lucania to the Garganian promontory. In the time of Augustus, Calabria was the district south and east of a line drawn from the neighbourhood of Tarentum to that of Brundisium, corresponding to the modern Terra d'Otranto. The principal cities were Tarentum (Taranto), Brundisium (Brindisi), and Hydruntum (Otranto), all of which are ports. The inhabitants were Sallentines and Calabrians or Messapians, both probably of Pre-Hellenic or Pelasgic race; Niebuhr, however, considered the Calabrians to be Oscan intruders distinct from the other tribes.

Ancient Calàbria was a country of low hills with very gentle ascents, having a soil of Tertiary limestone formation, no rivers, and scarcely any small streams, and, during summer, a climate of intolerable heat, but exceedingly fertile, producing the olive and vine.

Owing to its position Calabria was long defended by the Greeks against the Goths, Lombards, and Saracens, and was the last portion of Italy lost by the Byzantine emperors in the 11th century. In the time of the Norman monarchy there took place a curious change in the application of the name, the cause and exact date of which are not known with any certainty. An explanation possessing some probability is, however, given. The Byzantines, it is likely, extended the name Calabria to all their possessions in Southern Italy; and when their possessions in the south-eastern peninsula became greatly inferior in importance to that in the south-western (Bruttium) they applied the name to the latter instead of the former. It was not, however, till after the Norman Conquest that the name was universally employed in this the modern sense.

In modern times Calabria, until the consolidation of the Italian kingdom, was the name of one of the four provinces into which the continental part of the kingdom of Naples, or of the Two Sicilies, was formerly divided; and it is now the name given to three out of the sixty-nine provinces of the present division of Italy. It is the most southerly

of Italy, being bounded on the N. by the province of Basilicata, on the E. by the Gulf of Taranto, on the W. by the Tyrrhenian Sea, and on the S. by the Ionian. It extends from Cape Spartivento (37° 56′ N. lat.) to Monte Pollino on the southern border of Basilicata (40° 0′ N. lat.)

The territory is well watered, and exceedingly rugged and mountainous; but the summits of the hills are covered with extensive forests of oak, beech, elm, and pine, and towards the coast the branches of the Apennines open up into fertile valleys. Earthquakes and violent storms are very common; and there is extreme heat during the summer season, on the approach of which the wealthier inhabitants migrate annually to the lofty table-land of La Sila, where their flocks are fattened in the extensive pastures. The agriculture of Calabria is in a very rude and barbarous condition, a circumstance which is partly attributable to the extreme fertility of the soil. The principal productions are corn, wine, raw silk, olive oil of an inferior quality, cotton, rice, liquorice, and saffron. Manna, collected from the manna-ash (*Ornus rotundifolia*), was at one time a somewhat important article of commerce; but very little is now collected. Oranges, lemons, figs, mulberries, honey, and tobacco are also produced. The horses of Calabria are remarkable for their high spirit and compact form. There are considerable fisheries of the tunny, the swordfish, the anchovy, and mullet.

The three provinces into which Calabria is now divided are Calabria Citeriore, Calabria Ulteriore Seconda, and Calabria Ulteriore Prima.

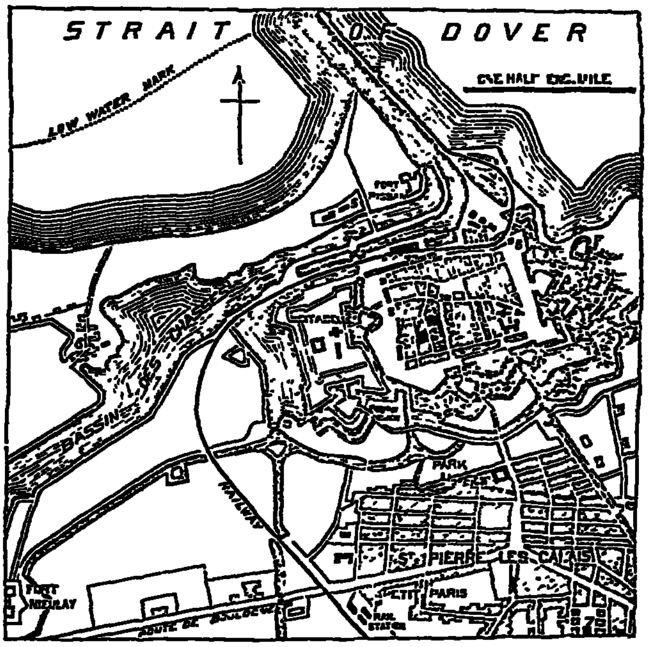
Calabria Citeriore, or Cosenza, is the most northern of the three provinces, and has an area of 2613 square miles, with a population in 1871 of 440,468. The southern and central districts are covered by the vast forests of La Sila, which furnished timber for the navies of antiquity. The principal rivers are the Crati, which after a course of 60 miles falls into the Gulf of Taranto, and the Neto, which rises in the heart of La Sila, and falls into the Adriatic. The principal towns are Cosenza, Rossano, Paola, and Castrovillari.

Calabria Ulteriore Seconda, or Catanzaro, on the south of Calabria Citra, having a coast line from the Punta dell' Alice to the Callipari on the east, and from the Savuto to the mouth of the Messina on the west, has an area of 2100 square miles. Population (1871) 412,226. At Catanzaro is a manufactory of silk; at Maida there are some seams of coal, antimony, and alabaster, which might be made available for exports. The principal towns are Catanzaro, Cotrone, Nicastro, and Monteleone.

Calabria Ulteriore Prima, or Reggio, the most southerly province of Italy, contains an area of 1250 square miles, with a population (1871) of 353,608. On the northern frontier are the mines of Lo Stilo, from which the iron is obtained for the Government foundries. The principal towns are Reggio, Gerace, and Palmi. A railway line now runs from Reggio to Taranto, along the coast of the Ionian Sea and the Gulf of Taranto.

CALAHORRA, the capital of the judicial district and diocese of the same name, in the province of Logroño, Spain, 24 miles S.E. of Logroño, in 42° 12′ N. lat., 2° 0′ W. long. It occupies an elevated site on the left bank of the River Cidacos, near its junction with the Ebro, and contains a cathedral in the mixed Gothic style, dating mainly from the 15th century, an episcopal palace, and several conventual and other schools. The climate is cold and damp, but the soil in the neighbourhood produces in abundance grain, pulse, flax, wine, and oil. Population in 1860, 7106. Calahorra is the ancient *Calagurris Nassica*, celebrated for its extraordinary fidelity to Sertorius in his war with Pompey and Metellus; and in the suburbs may still be traced the remains of an ancient Roman circus, an aqueduct, and a naumachia. Under the empire it was a municipium, and enjoyed the rights of Roman citizenship. It was the birthplace of Quintilian.

CALAIS, a town of France, capital of a canton of the same name, in the arrondissement of Boulogne and the department of Pas de Calais, 26 miles E.S.E. of Dover, and 185 miles by rail from Paris, in 50° 57′ 45″ N. lat., 1° 51′ E. long. Calais is a fortress of the first class, and was formerly a place of great strength, but it would now probably not be able to defend itself long against modern artillery. It is built in a rectangular form, having one of its longer sides towards the sea, while on the E. and S. it is surrounded by low and marshy ground which can be flooded to strengthen its defences. Overlooking the town on the W. is the citadel, erected in 1641 by Cardinal



Plan of Calais.

1. Church of Nôtre-Dame.
2. Church of the Courgain.
3. Hotel de Ville and Place de l'Armée.
4. Museum and Theatre
5. Bathing establishment.
6. Lighthouse.
7. Hotel de Ville de St Pierre les Calais.

Richelieu. In the centre of the town is the great market-place, in which stands the Hôtel de Ville (rebuilt in 1740, restored in 1867), with busts of Eustache de St Pierre, the Duc de Guise, and Cardinal Richelieu. Near the Hôtel de Ville is the *Tour du guet*, or watch-tower, used as a lighthouse until 1848. The Church of Nôtre Dame was almost entirely rebuilt at the end of the 15th century, during the English occupancy of Calais; its lofty tower serves as a landmark for sailors. At the end of the Rue de la Prison is the Hôtel de Guise, built as a guildhall for the English woolstaplers. It was given to the Duc de Guise as a reward for the recapture of Calais, and hence its name. The building which was formerly the Hôtel Dessin, immortalized by Sterne in the *Sentimental Journey*, is now used as a museum. The harbour of Calais is shallow, admitting vessels of from 400 to 500 tons only at high water. The French Government contemplates the construction of a large harbour of refuge near Calais. There are two lighthouses at the entrance to the harbour, and a still larger one on the fortifications, with a revolving light visible 20 miles off. The principal institutions are the schools of design, hydrography, and artillery, a public library with 10,000 volumes, and public baths. The imports are chiefly from Great Britain, and consist of coal, iron, woollen and cotton fabrics, linen, skins, machinery, and colonial produce. Of late years the importation of timber

from Norway has greatly increased. The exports comprise corn, wine and spirits, eggs, silk, fruit, vegetables, glass, and sugar. The fisheries are much less important than those of Boulogne. The manufacture of *tulle* or bobbin-net was introduced from Nottingham by the English in 1818, and is one of the main sources of the prosperity of the town and suburbs. Calais communicates with Great Britain by submarine telegraph, laid down in 1851. Steamers carrying the mails cross twice a day to Dover and back. It is the principal landing-place for English travellers on the Continent. The number of passengers who crossed both ways was 208,432 in 1875, being an increase of 66 per cent. in the last ten years. The terminus of the proposed tunnel beneath the channel is near Sangatte, a village six miles west of Calais. The project has received the sanction of the French and English Governments. Population (in 1872) 12,843; the adjoining manufacturing suburb of St Pierre les Calais had 20,409 inhabitants in 1872, more than 1800 of whom were English.

Calais was a petty fishing-village, with a natural harbour at the mouth of a stream, till the end of the 10th century. It was first improved by Baldwin IV., count of Flanders, in 997, and afterwards, in 1224, was regularly fortified by Phillip of France, count of Boulogne. It was besieged in 1346, after the battle of Crécy, by Edward III., and held out resolutely by the bravery of Jean de Vienne, its governor, till famine forced it to surrender. Its inhabitants were saved from the cruel fate with which Edward menaced them by the devotion of Eustache de St Pierre and six of the chief citizens, who were themselves spared at the prayer of Queen Philippa. The city remained in the hands of the English till 1558, when it was taken by the duke of Guise at the head of 30,000 men, from the ill-provided English garrison only 800 strong, after a siege of seven days. It was held by the Spaniards from 1595 to 1598, but was restored to France by the treaty of Vervins.

CALAMIS. See ARCHÆOLOGY, vol. ii. p. 354.

CALAMY, EDMUND (1600–1666), a Presbyterian divine, was born at London in February 1600, and educated at Pembroke Hall, Cambridge, where his opposition to the Arminian party, then powerful in that society, excluded him from a fellowship. Dr Felton, bishop of Ely, however, made him his chaplain, and gave him a living which he held till 1626. He then removed to Bury St Edmunds, where he acted as lecturer for ten years. In 1636 he was appointed to the rectory of Rochford in Essex, which was so unhealthy that he had soon to leave it; and in 1639 he was chosen minister of St Mary Aldermanbury in London. Upon the opening of the Long Parliament he distinguished himself in defence of the Presbyterian cause, and had a principal share in writing the work commonly known under the appellation *Smectymnuus*, against Episcopacy. The initials of the names of the several contributors formed the name under which it was published, viz., S. Marshal, E. Calamy, T. Young, M. Newcomen, and W. Spurstow. Calamy was afterwards an active member in the assembly of divines, and a strenuous opposer of sectaries. In Cromwell's time he lived privately, but was assiduous in promoting the king's return; for this he was afterwards offered a bishopric, but declined it. He was, however, made one of Charles's chaplains. He was ejected for nonconformity in 1662, and was so affected by the sight of the devastation caused by the great fire of London that he died shortly afterwards, October 29, 1666.

CALAMY, EDMUND (1671–1732), grandson of the preceding, was born in London, April 5, 1671. He was educated at a private academy, and studied at the university of Utrecht. While there, he declined an offer of a professor's chair in the university of Edinburgh made to him by Principal Carstairs, who had gone over on purpose to find a person properly qualified for such an office. After his return to England in 1691 he began to study divinity; and having joined the Nonconformists, he was in 1692 unanimously chosen assistant to Matthew Sylvester at Blackfriars. In 1694 he was ordained at Annesley's meeting-house in Little St Helen's, and soon afterwards was invited to become assistant to Daniel Williams in Hand-Alley. In 1702 he was chosen one of the lecturers in Salters' Hall, and in 1703 he succeeded Vincent Alsop as pastor of a large congregation in Westminster. He drew up the table of contents to *Baxter's History of his Life and Times*, which was sent to the press in 1696; made some remarks on the work itself, and added to it an index, and, reflecting on the usefulness of the book, he saw the expediency of continuing it, as Baxter's history came no farther than the year 1684. Accordingly, he composed an abridgment of it, with an account of many other ministers who were ejected after the restoration of Charles II.; their apology, containing the grounds of their nonconformity and practice as to stated and occasional communion with the Church of England; and a continuation of their history until the year 1691. This work was published in 1702. He afterwards published a moderate defence of nonconformity, in three tracts, in answer to some tracts of Dr Hoadly. In 1709 Calamy made a tour to Scotland, and had the degree of doctor of divinity conferred on him by the universities of Edinburgh, Aberdeen, and Glasgow. In 1713 he published a second edition of his *Abridgment of Baxter's History of his Life and Times*, in which, among various additions, there is a continuation of the history through the reigns of William and Anne, down to the passing of the Occasional Bill. At the end is subjoined the reformed liturgy, which was drawn up and presented to the bishops in 1661. In 1718 he wrote a vindication of his grandfather and several other persons against certain reflections cast upon them by Archdeacon Echard in his History of England; and in 1728 appeared his continuation of the account of the ministers, lecturers, masters, and fellows of colleges, and schoolmasters, who were ejected, after the Restoration in 1660, by or before the Act of Uniformity. He died June 3, 1732. Besides the pieces already mentioned, he published many occasional sermons.

CALAS, JEAN (1698–1762), a Protestant merchant at Toulouse, who was barbarously murdered under forms of law which were employed to shelter the sanguinary dictates of ignorant and fanatical zeal. He was born at La Caparède, in Languedoc, in 1698, and had lived forty years at Toulouse. His wife was an Englishwoman of French extraction. They had three sons and three daughters. His son Louis had embraced the Roman Catholic faith through the persuasions of a female domestic who had lived thirty years in the family. In October 1761 the family consisted of Calas, his wife, Marc-Antoine their son, who had been educated for the bar, Pierre their second son, and this domestic. Antoine being of a melancholy turn of mind, was continually dwelling on passages from authors on the subject of suicide, and one night in that month he hanged himself in his father's warehouse. The crowd, which collected on so shocking a discovery, took up the idea that he had been strangled by the family to prevent him from changing his religion, and that this was a common practice among Protestants. The officers of justice adopted the popular tale, and were supplied by the mob with what they accepted as conclusive evidence of the fact. The fraternity of White Penitents buried the body with great ceremony, and performed a solemn service for the deceased as a martyr; the Franciscans followed their example; and these formalities led to the popular belief in the guilt of the unhappy family.

Being all condemned to the rack in order to extort confession, they appealed to the parliament; but this body, being as weak as the subordinate magistrates, sentenced the father to the torture, ordinary and extraordinary, to be broken alive upon the wheel, and then to be burnt to ashes; which diabolical decree was carried into execution on the 9th of March 1762. Pierre Calas, the surviving son, was banished for life; the rest were acquitted. The distracted widow, however, found some friends, and among them Voltaire, who laid her case before the council of state at Versailles; and the parliament of Toulouse was ordered to transmit the proceedings. These the king and council unanimously agreed to annul; the chief magistrate of Toulouse was degraded and fined; old Calas was declared to have been innocent; and every imputation of guilt was removed from the family. See *Causes Célèbres*, tom. iv.

CALASIO, MARIO DE (1550–1620), a Franciscan, and professor of the Hebrew language at Rome, was born in 1550 at a small town in Abruzzo, from which he took his name. His *Concordance of the Bible* (which occupied him forty years) was published at Rome in 1621, the year after his death. This work has been highly approved and commended both by Protestants and Roman Catholics, and is indeed an admirable work; for, besides the Hebrew words of the Bible, which compose the body of the book, with the Latin version over against them, there are in the margin the differences between the Septuagint version and the Vulgate; so that at one view may be seen wherein the three Bibles agree, and wherein they differ. At the beginning of every article there is a kind of dictionary, which gives the signification of each Hebrew word, affords an opportunity of comparing it with other Oriental languages (Syriac, Arabic, and Chaldee), and is extremely useful for determining more exactly the true meaning of the Hebrew words. It has been several times reprinted; but the original edition is the best.

CALATAFIMI, a town of Sicily, in the province of Trapani and district of Alcamo, about 30 miles from Palermo. It lies between two hills in a fine corn country, and is celebrated for its cattle and its cheese In one of its churches, Santa Croce, there is a fine altar of mosaic work; and in the neighbourhood are the extensive and well-preserved ruins of Segesta. On the hill above the town stands the Saracenic castle of Kalat-al-Fimi, from which it derives its name, and about four miles distant is the battle-field on which Garibaldi won his first victory over the Neapolitans on May 15, 1860. Population, 9414.

CALATAYUD, a town of Spain, in the province of Saragossa in Aragon, 45 miles S.W. of the city of that name, in 41° 24′ N. lat., 1° 35′ W. long. It stands on the left bank of the River Jalon, near its confluence with the Jiloca, partly on the plain and partly on a rocky slope, which is covered with remains of ancient Moorish fortifications. It is generally spacious and well built, and contains several squares, the largest of which is used as the market-place, numerous convents, three hospitals, a fort, a provincial and municipal hall, an episcopal palace, a college, barracks, a theatre, and a bull-arena; there are also two *collegiatas*, or collegiate churches, both of them handsome edifices, and eleven other parish churches. The principal articles of manufacture are coarse brown paper, leather, and woollen stuffs. The soil of the neighbourhood is fertile and well cultivated. Calatayud is a Moorish city, and receives its name (Job's Castle) from Job the nephew of Musa; but it stands near the site of the ancient *Bilbilis*, the birthplace of the poet Martial, and was for the most part built out of its ruins. Population, 9830.

CALCAR, or KALCKER, JOHN DE (1499–1546), an eminent painter, born at Calcar, in the duchy of Clèves, in 1499. He was a disciple of Titian at Venice, and perfected himself by studying Raffaelle. He imitated those masters with such success as to deceive the most skilful critics. Among his various pieces is a Nativity, representing the angels around the infant Christ, which he arranged so that the light emanated wholly from the child. He died at Naples in 1546.

CALC-SPAR, or CALCAREOUS SPAR, is the popular name for certain of the crystalline forms of carbonate of lime or calcite ($CaCO_3$), containing in 100 parts 56 of lime and 44 of carbonic acid. The name includes only the varieties of calcite which belong to the rhombohedral or hexagonal order, to the exclusion of aragonite, which, having the same composition, belongs to the rhombic or right prismatic system, the two minerals forming a striking example of dimorphism. Calc-spar is also the same in chemical composition as marble, limestone, chalk, stalagmitic deposits, &c., which are among the most abundant ingredients in the rocky masses of the earth. The primary form of calc-spar is an obtuse rhombohedron, the faces of which are inclined to each other in the terminal edges at an angle of 105°·5, and all secondary crystals, however various they may be, tend to break or split up into that primary form. The variety of crystalline forms assumed by the mineral is exceedingly great, upwards of 800 being enumerated, of which 700 have been figured by Count Bournon in his treatise on carbonate of lime. The forms, although thus numerous, fall chiefly under the two heads of rhombohedrons, of which Iceland spar is a type, and scalenohedrons, which may be represented by the variety known as dog's-tooth spar. (See MINERALOGY.) Pure calc-spar is a transparent, colourless mineral with a vitreous lustre; its specific gravity is about 2·721; and in hardness it is intermediate between gypsum and fluor-spar, occupying the third place in the standard scale. It is frequently tinted in red, yellow, green, brown, and grey, from the presence of foreign matter. Pure, transparent rhombohedral crystals, obtained by cleavage or otherwise, are distinguished as Iceland spar, on account of the largest and finest crystals being found in that island, or as doubly-refracting spar (German, *Doppelspath*), from their exhibiting in the highest degree the double refraction of light. Before the blow-pipe it is reduced to caustic lime, and moistened with hydrochloric or other acid it displays a brisk effervescence. It occurs abundantly in almost all parts of the world,—Andreasberg in the Hartz and the Derbyshire lead mines being noted localities for large fine crystals. Magnificent cleavage rhombohedrons are obtained from Iceland, one having been noted which exceeded 6 yards long and 3 yards high. Professor Dana notices one nearly transparent crystal, weighing 165 lb, now in the cabinet of Yale College, found in the Rossie Lead Mine, New York State, and he cites a large number of other localities in the United States where crystals occur. Iceland spar, on account of its high double refracting property, is very extensively employed in optical research. It is most conveniently used in the form of a Nicol's prism, which consists of a long rhomboidal crystal cut obliquely into two equal portions in a plane perpendicular to the plane of the longer diagonal of the base. The two halves are cemented together in their original position with Canada balsam; and in this condition the ordinary ray undergoes total reflection from the prism, whilst the extraordinary ray passes through.

CALCHAS, the most famous soothsayer among the Greeks at the time of the Trojan war, was the son of Thestor. He foretold to the Greeks the length of time they would be engaged in the siege of Troy, and when the fleet was detained by adverse winds, at Aulis, he explained the cause and demanded the sacrifice of Iphigenia. When the Greeks were visited with pestilence on account of Chryseis, he disclosed to them the reasons of Apollo's

anger. After the return of the Greeks from Troy he is said to have retired to Colophon. According to the story, his death was due to chagrin at being surpassed in a trial of soothsaying skill by one Mopsus. It had long been predicted that he should die whenever he met his superior in divination.

CALCULATING MACHINES. Mathematicians and astronomers have felt in all ages the irksomeness of the labour of making necessary calculations, and this has led to the invention of various devices for shortening it. Some of these, such as the Abacus, Napier's Bones (invented by the father of logarithms), and the modern Sliding Rule, are rather aids to calculation than calculating machines. Pascal is believed to have been the original inventor of a calculating machine; its use was limited to addition, multiplication, &c., of sums of money, and as it required the constant intervention of a human operator the results were subject to the ordinary errors of manipulation. After him came the celebrated Leibnitz, Dr Saunderson, who, blind from his childhood, became professor of mathematics in Cambridge, and others. But all their machines were completely cast into the shade by the wonderful inventions of the late Charles Babbage. He knew well the immense value that absolutely correct tables possess for the astronomer and the navigator, and that a machine which could produce them with speed was a very great desideratum. The first calculating machine he invented he called a difference engine, because it was to calculate tables of numbers by the method of differences. By setting at the outset a few figures the attendant would obtain by a mechanical operation a long series of numbers absolutely correct. The difference engine was not intended to answer special questions, but to calculate and then print numerical tables, such as logarithm tables, tables for the *Nautical Almanac*, &c. An interesting account of some of the errors which are found in what are considered reliable tables is given in a paper by Babbage in the *Memoirs of the Astronomical Society*, 1827.

Every numerical table consists of a series of numbers which continuously increase or diminish. As an example take the squares of the natural numbers, 1, 4, 9, 16, 25, 36, &c. Designate this series by N. If we subtract each term from the one following it we get a new series, 3, 5, 7, 9, &c., which is called the series of first differences; designate this by Δ^1. If in the same way we subtract each term of this series from the succeeding term, we get what is called the series of second differences, every term of which is in this instance 2. Designate this series by Δ^2. As the different series were obtained by subtraction, it is quite evident that by reversing the process we shall obtain the original table. Suppose we are given the first terms of N, Δ^1, and Δ^2, *i.e.*, 1, 3, 2. If we add 3, the first term of Δ^1, to 1, the first term of N, we get 4, the second term of N; and if we add 2, the first term of Δ^2, to 3, the first term of Δ^1, we get 5, the second term of Δ^1; and this added to 4, the second term of N, gives us 9, the third term of N. Similarly we obtain 16 by adding 9, 5, and 2 together, and 25 by adding 16, 7, and 2. Hence, given 1, 3, 2, we can, by a process of additions, obtain the series of square numbers. All numerical tables can be calculated entirely by this method or by repetitions of it.

Table of Square Numbers, N	First Differences, Δ^1	Second Differences, Δ^2
1	3	2
4	5	2
9	7	2
16	9	
25		

The main characteristics of the difference engine, designed and partially constructed by Babbage, are these:—It consisted of several vertical columns of figure-wheels like large "draught men" one above another, to the number of six in each column. The natural numbers from 0 to 9 were cut on the rims of the figure wheels; hence each figure-wheel in a column could represent a digit. Thus the lowest wheel gave the units digit, the second wheel the tens digit. The number 5703 would be represented on the wheels of a column as in the margin. The different columns were to represent the successive series of differences above referred to, and were called the table column, the first difference column, &c.

"The mechanism was so contrived that whatever might be the numbers placed respectively on the figure wheels of each of the different columns, the following succession of operations took place as long as the handle was moved. Whatever number was found upon the column of first differences, would be added to the number found upon the table column. The same first difference remaining upon its own column, the number found upon the column of second differences would be added to that first difference." Similarly for all the other columns. For example, suppose we are calculating the cubes of the natural numbers. At a certain stage of the work we would find 125 shown by the wheels of the table column, 91 by those of the first difference column, 36 by those of the second difference column, and 6 on the lowest wheel of the third difference column. On making a turn of the handle the 91 would be added to the 125, which would then show 216; at the same time 36 would be added to the 91, so that the first difference column would then show 127; moreover 6 would be simultaneously added to the 36, which would thus become 42, and the 6 would remain unaltered. Another turn and we would get 343, 169, 48, 6 on the different columns. Had the engine been completed it would have had columns for six orders of differences, each of twenty places of figures, whilst the first three columns would each have had half a dozen additional figures.

	Table Column.	First Difference Column.	Second Difference Column.	Third Difference Column.
	1 2 5	9 1	3 6	6
After one Turn ...	2 1 6	1 2 7	4 2	6
After two Turns...	3 4 3	1 6 9	4 8	6

It was about 1822 that Babbage having constructed a small model of his engine sent an account of it to Sir Humphrey Davy, then president of the Royal Society of London. Government heard of the invention, and, having received from the Royal Society a favourable report on the merits and utility of the engine, advanced money towards its construction. Sums of money were at irregular intervals voted for this purpose; but so great were the difficulties to be overcome, so entirely new even were many of the tools necessary, so much time was occupied in testing the value of each proposed contrivance, that in 1834 only a portion was completed. The construction of the machine here stopped, although the Royal Society had again, in 1829, reported most favourably on the engine as regards its practicability, immense utility, and the progress it had made. The Government had already advanced £17,000 (over and above what Babbage had spent, besides giving his personal superintendence without any remuneration), and they saw no definite limit to the amount it would cost;

and Babbage had a delicacy in pressing for the completion of the difference engine, as he had recently designed a new machine, the analytical engine, which, if completed, would entirely supersede it. The portion completed is in King's College, London.

It will be noticed that the use of the difference engine was limited to the working of such problems as can be solved by successive additions or subtractions. The analytical engine, on the other hand, was designed to *work out* any problem that the superintendent knew *how* to solve. It consists of two parts, each of a number of vertical columns of figure wheels, similar to those of the difference engine; on the one set called the "variables," which we shall designate by V_1, V_2, &c., the numbers of the special problem or formula are placed; the other set is called the "mill," and performs the required operations of multiplication, division, addition, or subtraction. Its working was directed by means of two sets of cards—"operation" cards, which instructed the mill whether to multiply, divide, add, or subtract, and "variable" cards, which indicated to the mill the particular columns, *i.e.*, numbers on which it was to perform this operation. An example will make this clear. Suppose we wish to solve the equations

$$ax + by = c,$$
$$dx + fy = g.$$

On the wheels of V_1, the first column of the variables, the number a is placed, b on V_2, c on V_3, and so on. Six columns in all are required for this. It is evident that $x = \frac{fc - bg}{fa - bd}$. Hence, to get x, we require the products of f and c, b and g, &c. To get these the superintendent intimates to the mill by means of an "operation" card that a multiplication is to be performed, then points out by a "variable" card what are the two numbers, *i.e.*, the two columns to be multiplied, and on what column the result is to be placed. In the first case the columns indicated would be V_5, V_3, and V_7 respectively. By another operation card and another variable card, the mill would then be instructed to multiply the numbers on V_2 and V_6, and to place the result on V_8. Similarly ca and bd would be obtained on V_9 and V_{10}. The superintendent would then instruct the mill to subtract the number on V_8 from that on V_7, to place the result $(fc—bg)$ on V_{11}, and similarly, $fa—bd$ would be placed on V_{12}. By a new operation card the mill would now be put into a "dividing" state, and a variable card would tell it that V_{11} was to be divided by V_{12}, and the result given on V_{13}. This would be the value of x. Similarly for y. The number of cards can be greatly diminished. Thus, for the four multiplications one card would suffice. The cards are of pasteboard (say) and have holes punched in them,—a "multiplication" card having a certain number of holes bored in it and arranged in a particular way, a "division" card a different arrangement of holes, &c. The cards are so placed in the machine that certain levers drop through these holes, while others are unaffected, and the machinery in connection with the levers is put out of gear or not as is desired. In this way the mill is put into a condition in which it multiplies (say) the numbers indicated to it. The variable cards act in a similar manner. When an operation card and a variable card are given to the engine, the numbers on the assigned columns are transferred to the mill, the operation is performed, and the numbers and the result are placed on the proper columns. The series of cards used for any one problem would enable the machine to solve any other similar problem. Babbage says of the engine, "The analytical engine is therefore a machine of the most general nature. Whatever formula it is required to develop, the law of its development must be communicated to it by two sets of cards. When these have been placed the engine is special for that particular formula. The numerical constants must then be put on the wheels, and on setting the engine in motion it will calculate and print the numerical results of that formula." In the construction of this engine he overcame one of the greatest difficulties in such an instrument, that of effecting the carrying of tens. The engine was designed so as to foresee these carriages, and act upon that foresight, and thus a great reduction of the time necessary to make a given calculation was at once obtained by effecting all carriages simultaneously instead of in succession. He says of it, "The analytical engine will contain—1°, apparatus for printing on paper, one, or if required, two copies of its results; 2°, means for producing a stereotype mould of the table or results it computes. The engine would compute all the tables it would itself require. It would have the power of expressing every number to fifty places of figures." It would multiply two numbers of fifty figures each, and print the result in one minute. Its construction was never begun, but Babbage left complete plans of every part of it.

In the *Edinburgh Review* for July 1834 appeared an account of the principles of Babbage's difference engine. Herr George Schentz, a printer at Stockholm, read it, and shortly afterwards he and his son Edward set about constructing a calculating machine. By 1843 they produced one capable of calculating series with terms of five figures, with three orders of differences, also of five figures each, and of printing its results. Provided with a certificate to this effect from the Royal Swedish Academy of Sciences, they endeavoured unsuccessfully to get orders for their machine. In 1853, with the aid of grants from the Swedish Government, the Messrs Scheutz finished a second machine which was exhibited in England, and at the Paris exhibition of 1855. It eventually went to America. It was about the size of a small square pianoforte. It could calculate series with four orders of differences each of fifteen figures. It printed the results to eight figures, the last of which was capable of an automatic correction where necessary for those omitted. "It could calculate and stereotype without a chance of error two and a half pages of figures in the same time that a skilful compositor would take to set up the types for one single page."

A new machine by the Messrs Scheutz was constructed about 1860 by Messrs Donkin for the Registrar-General for the sum of £1200. It has been used in the calculation of some of the tables in the *English Life Table*, published in 1864. Dr Farr says of it, "The machine has been extensively tried, and it has upon the whole answered every expectation. But it is a delicate instrument, and requires considerable skill in the manipulation. It approaches infallibility in certain respects; but it is not infallible, except in very skilful hands. The weakest point is the printing apparatus, and that admits of evident improvement."

M. Staffel and M. Thomas (de Colmar) have invented machines which can perform addition, subtraction, multiplication, division, and extraction of the square root. M. Thomas's machine is extensively used.

Sir William Thomson has recently invented an instrument (no description of which has yet been printed) which is able to solve any linear differential equation with variable coefficients.

Professor Tait has also invented the principle of a machine, which, if constructed, will integrate any linear differential equation of the second order with variable coefficients.

See the article "Calculating Machines" in Walford's *Insurance Cyclopædia*, where many references will be found, and a translation of General Menambrea's article on Babbage's Analytical Engine in Taylor's *Scientific Memoirs*, vol. iii. (P. S. L.)

CALCULUS. See DIFFERENTIAL AND INTEGRAL CALCULUS.

CALCUTTA, the capital of India, and seat of the Supreme Government, is situated on the east bank of the Húglí River, in latitude 22° 33′ 47″ N. and longitude 88° 23′ 34″ E. It lies about 80 miles from the seaboard, and receives the accumulated produce which the two great river systems of the Ganges and the Brahmaputra collect throughout the provinces of Bengal and Assam. From a cluster of mud villages at the close of the 17th century, it has advanced with a rapid growth to a densely inhabited metropolis, which, with its four suburbs, contains a population of 892,429 souls. The central portion, which forms the Calcutta municipality, has a population returned in 1872 at 447,601. In the same year its maritime trade amounted to $52\frac{1}{2}$ millions sterling, of which the exports formed $31\frac{3}{4}$ millions, and the imports $20\frac{3}{4}$, showing an excess of exports over imports of 11 millions sterling.

The history of Calcutta practically dates from the year 1686. In 1596 it had obtained a brief entry as a rent-paying village in the survey of Bengal executed by command of the Emperor Akbar. But it was not till 90 years later that it emerged into history. In 1686 the English merchants at Húglí, finding themselves compelled to quit their factory in consequence of a rupture with the Mughul authorities, retreated about 26 miles down the river to Sutánatí, a village on the banks of the Húglí, now within the boundaries of Calcutta. Their new settlement soon extended itself along the river bank to the then village of Calcutta, and by degrees the cluster of neighbouring hamlets grew into the present town. In 1689–90 the Bengal servants of the East India Company determined to make it their headquarters. In 1696 they built the original Fort William, and in 1700 they formally purchased the three villages of Sutánatí, Calcutta, and Gobíndpur from Prince Azim, son of the Emperor Aurungzebe.

The site thus chosen had an excellent anchorage, and was defended by the river from the Marhattás, who harried the districts on the other side. A fort, subsequently rebuilt on the Vauban principle, and a moat,

designed to form a semicircle round the town, and to be connected at both ends with the river, but which was never completed, combined with the natural position of Calcutta to render it one of the safest places for trade in India during the expiring struggles of the Mughul empire. It grew up without any fixed plan, and with little regard to the sanitary arrangements required for a town. Some parts of it lie below water mark on the Húglí, and its low level throughout rendered its drainage a most difficult problem. Until far on in the last century, the jungle and paddy fields closely hemmed in the European mansions with a circle of malaria; the vast plain (*maidán*), with its gardens and promenades, where the fashion of Calcutta now displays itself every evening, was then a swamp during three months of each year; the spacious quadrangle known as Wellington Square was built upon a filthy creek. A legend relates how one-fourth of the European inhabitants perished in twelve months, and during seventy years the mortality was so great that the name of Calcutta, derived from the village of Kálighát, was identified by mariners with Golgotha, the place of a skull.

The chief event in the history of Calcutta is the sack of the town and the capture of Fort William in 1756, by Suráj-ud-Daulá, the Nawáb of Bengal. The majority of the English officials took ship and fled to the mouth of the Húglí River. The Europeans who remained were compelled, after a short resistance, to surrender themselves to the mercies of the young prince. The prisoners, numbering 146 persons, were driven at the point of the sword into the guard-room, a chamber scarcely 20 feet square, with but two small windows. Next morning only 23 were taken out alive, among them Mr Holwell, the annalist of the "Black Hole." This event took place on June 20, 1756. The Mahometans retained possession of Calcutta for about seven months, and during this brief period the

name of the town was changed in official documents to Alinagar. In January 1757 the expedition despatched from Madras, under the command of Admiral Watson and Colonel Clive, regained possession of the city. They found many of the houses of the English residents demolished, and others damaged by fire. The old church of St John's lay in ruins. The native portion of the town had also suffered much. Everything of value had been swept away, except the merchandise of the Company within the fort, which had been reserved for the Nawáb. The battle of Plassey was fought on June 23d, 1757, exactly twelve months after the capture of Calcutta. Mír Jáfar, the nominee of the English, was created Nawáb of Bengal, and by the treaty which raised him to this position he agreed to make restitution to the Calcutta merchants for their losses. The English received £500,000, the Hindus and Mahometans £200,000, and the Armenians £70,000. By another clause in this treaty the Company was permitted to establish a mint, the visible sign in India of territorial sovereignty, and the first coin, still bearing the name of the Delhi emperor, was issued on August 19th, 1757. The restitution money was divided among the sufferers by a committee of the most respectable inhabitants. Commerce rapidly revived, and the ruined city was rebuilt. Modern Calcutta dates from 1757. The old fort was abandoned, and its site devoted to the Customs House and other Government offices. A new fort, the present Fort William, was commenced by Clive, a short distance lower down the River Húglí. It was not finished till 1773, and is said to have cost two millions sterling. At this time also the *maidán*, the park of Calcutta, was formed; and the salubrity of its position induced the European inhabitants gradually to shift their dwellings eastward, and to occupy what is now the Chauringhi (Chowringhee) quarter.

From this time the history of Calcutta presents a smooth narrative of advancing prosperity. No outbreak of civil war nor any episode of disaster has disturbed its progress, nor have the calamities of the climate ever done mischief which could not be easily repaired. A great park (*maidán*), intersected by roads, and ornamented by a garden, stretches along the river bank. The fort rises from it on its western side, the stately mansions of Chauringhi with Government House, the high court, and other public offices, line its eastern and northern flank. Beyond the European quarter lie the densely populated clusters of huts or "villages" which compose the native city and suburbs. Several fine squares, with large reservoirs and gardens, adorn the city, and broad well-metalled streets connect its various extremities.

Up to 1707, when Calcutta was first declared a presidency, it had been dependent upon the older English settlement at Madras. From 1707 to 1773 the presidencies were maintained on a footing of equality; but in the latter year the Act of Parliament was passed, which provided that the presidency of Bengal should exercise a control over the other possessions of the Company; that the chief of that presidency should be styled Governor-General; and that a supreme court of judicature should be established at Calcutta. In the previous year, 1772, Warren Hastings had taken under the immediate management of the Company's servants the general administration of Bengal, which had hitherto been left in the hands of the old Mahometan officials, and had removed the treasury from Murshidábád to Calcutta. The latter town thus became the capital of Bengal, and the seat of the Supreme Government in India. In 1834 the Governor-General of Bengal was created Governor-General of India, and was permitted to appoint a Deputy-Governor to manage the affairs of Lower Bengal during his occasional absence. It was not until 1854 that a separate head was appointed for Bengal, who, under the style of Lieutenant-Governor, exercises the same powers in civil matters as those vested in the Governors in Council of Madras or Bombay, although subject to closer supervision by the Supreme Government. Calcutta is thus at present the seat both of the Supreme and the Local Government, each with an independent set of offices. Government House, the official residence of the Governor-General of India, or Viceroy, is a magnificent pile of buildings to the north of the fort and the *maidán*, built by Lord Wellesley in 1804. The official residence of the Lieutenant-Governor of Bengal is a house called Belvedere, in Alipur, the southern suburb of Calcutta. Proposals have been made from time to time to remove the seat of the Supreme Government from Calcutta. Its unhealthiness, especially in the rainy season, its remoteness from the centre of Hindustán, and its distance from England, have each been animadverted upon. These disadvantages of Calcutta have now, however, been almost entirely removed, or their consequences have been mitigated, by the conquests of science and modern engineering. The railway and the telegraph have brought the Viceroy at Calcutta into close contact with every corner of India; while an ample water supply, improved drainage, and other sanitary reforms, have rendered Calcutta the healthiest city in the East,—healthier, indeed, than some of the great European towns. English civilization has thus enabled Calcutta to remain the political capital of India. The same agency still secures the city in her monopoly of the sea-borne trade of Bengal. The River Húglí has long ceased to be the main channel of the Ganges; but Calcutta alone of all the successive river capitals of Bengal has overcome the difficulties incident to its position as a deltaic centre of commerce. Strenuous efforts of engineering are required to keep open the "Nadiyá Rivers," namely, the three off-shoots of the Ganges which combine to form the Húglí. Still greater watchfulness and more extensive operations are demanded by the Húglí itself below Calcutta, to save it from the fate of other deltaic streams, and prevent it from gradually silting up. In 1853 the deterioration of the Húglí channel led to a proposal to found an auxiliary port to Calcutta on the Matlah, another mouth of the Ganges. A committee, then appointed to inquire into the subject, reported that "the River Húglí was deteriorating gradually and progressively." At that time "science had done nothing to aid in facilities for navigation," but since then everything has been done which the foresight of modern knowledge could suggest, or the power of modern capital could achieve. Observations on the condition of the river are taken almost hourly, gigantic steam dredgers are continually at work, and the shifting of the shoals is carefully recorded. By these means the port of Calcutta has been kept open for ships of the largest tonnage, and now seems to have out-lived the danger which threatened it.

Statistics.—Calcutta may, in one sense, be said to extend across the Húglí, and to include Howrah on the western side of the river, as well as the three separate municipalities on the eastern bank, known as the suburbs of Calcutta, the north suburban town, and the south suburban town. The total *population* of the area thus defined was returned by the census of 1872 at 892,429 souls. Calcutta proper, or the central portion, which lies, roughly speaking, between the old Marhatta ditch and the Húglí, is governed by a distinct municipality. In 1752 Mr Holwell estimated the number of houses within its limits at 51,132, and the inhabitants at 409,056 persons; but both these estimates were probably much too high; in 1822 the number of inhabitants was returned at 179,917; in 1831 at 187,081; in 1850 at 361,369; and in 1866 at 377,924. In 1872 a regular census was taken under the conduct of the municipality. The results present features of doubtful accuracy. They were as follows:—Area, 8 square miles; number of houses, 38,864; population,—Hindus, 291,194; Mahometans, 133,131; Buddhists, 863; Christians, 21,356; "other" denominations not separately classified, 1031

grand total, 447,601; total of males of all denominations, 299,857; females, 147,744; average number of persons per house, 11; number of persons per square mile, 55,950. The length of the *roads* in the town is about 120 miles. The present *governing body* was created in accordance with the provisions of Act 6 of 1863 (Bengal Council). It consists of the justices of the peace for Calcutta, with a salaried chairman, who is a member of the civil service. All the members are nominated by the Government, but a deputy chairman is chosen by the justices out of their own body. As the justices are not in any sense representative, the power and responsibility are to a great extent centred in the chairman; but of late years, by means of departmental committees, the co-operation of the ordinary members has been enlisted. Out of about 100 justices who are resident in Calcutta exactly one-half are Europeans. In 1874 the ordinary revenue of the municipality amounted to £240,656, of which £160,000 was raised by rates, and £37,000 by licences. The ordinary expenditure for the same year amounted to £233,374, of which £80,000 was devoted to interest on loans and sinking fund, £32,000 to general expenses, £30,000 to roads, two items of £22,000 to lighting and water supply, and £13,000 to conservancy. Including capital account, receipts, loans, suspense account, and cash balances, the total amount at the disposal of the justices during the year was £433,938. The aggregate expenditure under both revenue and capital account amounted to £382,823. The total loan liabilities of the corporation are £1,466,060, and the total of interest and sinking fund payable yearly is £100,474. The average rate of municipal taxation per head of the population is about 10s. 8d. The most important undertaking under the care of the municipality is the *water supply*. The present system dates from 1865, when the sanction of Government was given to the construction of works which now pour upwards of 6 million gallons a day of filtered water into the city. The source of supply is from the Húglí at Palta, about 16 miles above Calcutta. The works there consist of two large suction pipes, 30 inches in diameter, through which the water is drawn from the river by three engines, each of 50 horse power nominal; the water is then passed into six settling tanks, each 500 feet long by 250 feet wide. Here it is allowed to stand for 36 hours, when it is permitted to run off to the filters, eight in number, the area of each being 200 by 100 feet. After filtration the water is made to flow over a marble platform, where its purity can be observed. It is then conducted to Calcutta by a 42-inch iron main. These works cost £525,432. They were finished in 1870, and connected with pipes laid under 100 miles of streets. The total number of house connections up to December 31, 1874, was 8159. The total quantity of water delivered during that year amounted to 2,524,566,300 gallons, being considerably over the estimated average of 6 million gallons daily, or about 13 gallons per head of the population. The total cost for the same year of the water-supply (inclusive of interest) was £55,547, or about 5d. per 1000 gallons.

The *drainage* works are on an equally effective scale. The main sewers are underground, and for the proper discharge of their contents in the direction of the Salt Lake, a pumping station is maintained at an annual cost of £3000. The system of underground drainage, although not entirely completed, had cost in 1874 a capital sum of £620,000 In 1863, on the constitution of the present municipality, a *health officer* with an adequate establishment was appointed The practice of throwing corpses into the river has been put down, and the burning *ghâts* and burial-grounds have been placed under supervision. All refuse and night-soil are removed by the municipality, and conveyed by a special railway to the Salt Lake. The town is lighted by a private *gas company*, 2723 gas lamps and 730 oil lamps being paid for at the public expense. The fire brigade consists of 2 steam fire-engines, and 5 hand engines, its annual cost being about £2000. The *police* of Calcutta is under the control of a commissioner, who is also the chairman of the justices Beneath him there is a deputy-commissioner. The force consists of 4 superintendents, 155 subordinate officers of various grades, 1292 constables, and 6 mounted constables, maintained in 1873 at a cost of £41,227, of which Government contributed one-fourth. Several minor bodies, such as the river police, Government guards, &c., bring the entire strength of the force in the town and on the river to 2313 men. The great majority are natives, the number of European sergeants and constables being only 50.

In 1872–73 the statistics of *education* in Calcutta were as follows:—There were 3 Government colleges, namely, the Presidency College, founded in 1855, and attended by 709 pupils; the Sanskrit College, established in 1824, attended by 26 adult pupils, of whom 17 are Bráhmans; the Calcutta Madrásá or Mahometan College founded in 1781, number of pupils 528. There are also five colleges mainly supported by missionary efforts, aided by Government, and attended by 305 pupils The total number of schools in Calcutta reported on by the Educational Department is 260, with 19,445 scholars; 157 of them are male schools, teaching 16,155 boys; the remaining 103 are for girls, and teach 3290 pupils. According to a different principle of classification, 36 schools teach English to 9445 boys, 121 teach the vernacular only to 6620 boys, 99 are vernacular schools for girls with 3244 pupils, and 4 are normal schools, instructing 90 male teachers and 46 female. Of the total number of pupils in these schools, 47·7 per cent. are ascertained to be Hindus, 13·5 Christians, 2·6 Musalmáns, and the remaining 36·2 per cent. are of unascertained religions. The total ascertained expenditure was £25,011, of which sum the Government contributed £9160. The Government School of Art was attended in 1872–73 by 94 students, of whom 88 are Hindus, 4 Musalmáns, and 2 Eurasians. Calcutta has also an important school of medicine, or medical college, with a large hospital attached and every facility for a thorough scientific training.

The *medical charities* of Calcutta comprise the Medical College Hospital, just named the General Hospital, the Native or Mayo Hospital, the Municipal Pauper Hospital, and minor dispensaries. Of these the General Hospital is confined almost solely to Europeans. The total amount contributed by Government to these institutions is £30,000. The number of persons treated during the year 1872–73 was 251,039, of whom 20,805 were indoor patients. Of these 64·9 per cent. were men, 16·3 women, and 18·8 children. The rate of mortality in cholera cases was 484·3 for every thousand treated.

Mortuary returns are collected in Calcutta by the police inspectors, and compared with the registers kept by paid clerks of the municipality at the burning *ghâts* and burial-grounds. In 1873 the total number of deaths thus ascertained was 11,557, or 25·32 per thousand. The death rate among the Christians was 31·5, among the Hindus 26·1, and among the Mahometans 24·7. The highest death rate was in January, November, and December, and the lowest in June and July.

The mean temperature of Calcutta is about 79° Fahr. The highest temperature recorded during the last 18 years is 106° in the shade, and the lowest 52°·7. The extreme range is therefore a little over 53°, while the mean temperatures of December and May, the coldest and hottest months, are 68°·5 and 85° respectively. The average rainfall during 36 years has been 66 inches,—the highest rainfall on record being 93·31 inches in 1871, and the lowest 43·61 inches in 1837. By far the greater part of the rain falls between the months of June and October.

Like the rest of the seaboard of the Bay of Bengal, Calcutta is exposed to periodical cyclones, which do much mischief. The greatest pressure of the wind registered is 50 lb to the square foot. In the storms of 1864 and 1867 the anemometer was blown away. A great loss of life and property was caused along the Húglí by the storm of October 5th 1864. In Calcutta and its suburbs 49 persons were killed, and 16 wounded, 102 brick houses were destroyed, and 563 severely damaged; 40,698 tiled and straw huts were levelled with the ground. The destruction of shipping in the port of Calcutta appears greatly to have exceeded that on record in any previous storm. Out of 195 vessels only 23 remained uninjured, and 31, with an aggregate tonnage of 27,653 tons, were totally wrecked. On November 2, 1867, the force of the wind was not less violent, but there was no storm wave, and consequently the amount of damage done was much less.

The Port of Calcutta, extending 10 miles along the Húglí, with an average width of working channel of 250 yards, and with moorings for 169 vessels, is under the management of a body of 9 European gentlemen styled "Commissioners for making Improvements in the Port of Calcutta." This body was constituted in 1870, and has since that date received considerable additions to its powers. In 1871 they were appointed "Bridge Commissioners," to take charge of the floating bridge over the Húglí, and to work it when completed. This bridge, finished in 1874, now supplies a permanent connection between Calcutta and the railway terminus on the Howrah side of the river. It is constructed on pontoons, and affords a continuous roadway for foot passengers and vehicles. The traffic returns for 41 weeks in 1875 were £7593; the cost of the bridge has been £220,000. The main duty of the Port Commissioners has hitherto consisted in providing accommodation, by jetties and warehouses, for the shipping and native boats, which carry on the great and increasing trade of Calcutta.

In the year 1873–74 the income of the commissioners from all sources was £114,709, and the expenditure £78,260. The total amount of capital expended up to that year was £580,339, including a debt of £400,123. The number of vessels arriving and departing in 1861–62 was 1793, with an aggregate tonnage of 1,337,632 tons; in 1873–74, the number of vessels was 1927, tonnage 2,437,447. The number of steamers, and especially of steamers passing through the Suez Canal, is greatly on the increase.

The growth of the commerce of Calcutta may be seen from the following figures:—In 1820-21 the total value of the exports and imports, including treasure, was £10,454,910; in 1830-31, £8,758,352; in 1840-41, £15,292,697; in 1850-51, £18,754,625; in 1860-61, £31,794,671; in 1870-71, £49,316,782. The value of the customs duties (including salt) was in 1820-21, £151,317; 1830-31, £121,321; 1840-41, £495,515; 1850-51, £1,088,285; 1860-61, £2,270,654; 1870-71, £3,548,628. Cotton goods first became an important article of import in 1824; oil seeds were first exported in 1835; the exports of jute on a large scale date from 1850, those of tea from 1854. Among the chief articles of import in 1870-71 were—apparel, value £136,767; beer, £140,256; coal, £162,135; cotton manufactured, £11,624,712; machinery, £194,192; metals, £1,811,547; railway materials, £710,257; salt, £652,622; spices, £150,166; spirits, £162,635; wine, £214,191; wood, £158,663; woollen manufactures, £247,116; treasure, £2,255,244; Government shipments, £331,557; total value of imports, £21,198,472. Among the chief articles of export in 1870-71 were—cotton raw, £2,020,156; cotton manufactured, £211,625; dyeing materials, £158,118; grain and pulse, £2,630,451; hides and skins, £1,572,655; indigo, £2,225,202; jute, £2,585,220; jute manufactured, £784,222; lac, £194,076; metals, £215,920; opium, £5,450,885; saltpetre, £449,122; seeds, £2,021,117; silk, £1,066,301; silk manufactured, £244,076; spices, £215,612; sugar, £674,142; tea, £1,117,712; tobacco, £152,716; woollen manufactures, £128,652; bullion and treasure, £1,621,633; Government treasure, £225,624; total value of exports, £22,118,310.

The internal trade of Calcutta is conducted partly by railway, and partly by water traffic. There is no railway station within the limits of the municipality, but three separate railways have their terminus in the immediate neighbourhood. The East Indian Railway, whose terminus is across the river at Hówrah, brings down the produce of the North-Western Provinces and Behar, and connects Calcutta with the general railway system of the Peninsula. The Eastern Bengal Railway and the South-Eastern Railway have their terminus at Sïáldah, an eastern suburb of Calcutta. The former is an important line running across the Delta to the junction of the Ganges and Brahmaputra at Goalandá. The latter is a short railway, intended to connect the metropolis with Port Canning, in the Sundarbans. The three chief lines of water traffic are (1), the Calcutta canals, a chain of channels and rivers passing round and through the Sundarbans, open at all seasons of the year, and affording the main line of communication with the Ganges and the Brahmaputra; (2), the Nadiyá rivers, three in number, which branch off in a more directly southern course from the Ganges, above its junction with the Brahmaputra, and ultimately become the Húglí—these are with difficulty navigable during the dry season; (3), the Midnapur and Hijili canals, leading south towards Orissa. (W. W. H.)

CALDANI, Leopold Marco Antonio (1725–1813), a distinguished Italian anatomist and physician, was born at Bologna in 1725. After holding various minor appointments, he was chosen assistant to the celebrated anatomist Morgagni at Padua; but disgusted with the envy which his distinguished position drew upon him, he removed to Venice. Soon after, however, he was appointed to the professorship of the theory of medicine, with the promise of being elected to succeed Morgagni, who was then old and infirm. In 1772 he published his *Elements of Pathology*, and soon afterwards the *Elements of Physiology*. In the same year he took possession of the chair of anatomy, vacant by the death of Morgagni, and endeavoured, though without success, to found an anatomical museum. At the age of seventy-six, though threatened with blindness, he published, with the assistance of his nephew, a valuable series of anatomical plates. He died in 1813, at the age of eighty-eight.

CALDER, Sir Robert (1745–1818), Baronet, was born at Elgin, in Scotland, July 2, 1745 (o. s.) He belonged to a very ancient family of Morayshire, and was the second son of Sir Thomas Calder of Muirton. He was educated at the grammar school of Elgin, and at the age of fourteen entered the British navy as midshipman. In 1766 he was serving as lieutenant of the "*Essex*," under captain the Honourable George Faulkner, in the West Indies. Promotion came slowly, and it was not till 1782 that he attained the rank of post-captain. He acquitted himself honourably in the various services to which he was called, but for a long time had no opportunity of distinguishing himself. In 1796 he was named captain of the fleet by Sir John Jervis, and took part in the great battle off Cape St Vincent (February 14, 1797). He was selected as bearer of the despatches announcing the victory, and on that occasion was knighted by George III. He also received the thanks of parliament, and in the following year was created a baronet. In 1799 he became rear-admiral; and in 1801 he was despatched with a small squadron in pursuit of a French force, under Admiral Gantheaume, conveying supplies to the French in Egypt. In this pursuit he was not successful, and returning home at the peace, he struck his flag. When the war again broke out he was recalled to service, was promoted vice-admiral in 1804, and was employed in the following year in the blockade of the ports of Ferrol and Coruña, in which (amongst other ports) ships were preparing for the invasion of England by Napoleon I. He held his position with a force greatly inferior to that of the enemy, and refused to be enticed out to sea. On its becoming known that the first movement directed by Napoleon was the raising of the blockade of Ferrol, Rear-admiral Stirling was ordered to join Sir R. Calder and cruise with him to intercept the fleets of France and Spain on their passage to Brest. The approach of the enemy was concealed by a fog; but on July 22, 1805, their fleet came in sight. It still outnumbered the British force; but Sir Robert entered into action. After a combat of four hours, during which he captured two Spanish ships, he gave orders to discontinue the action. He offered battle again on the two following days, but the challenge was not accepted. The French admiral, Villeneuve, however, did not pursue his voyage, but took refuge in Ferrol. In the judgment of Napoleon, his scheme of invasion was baffled by this day's action; but much indignation was felt in England at the failure of Calder to win a complete victory. He was, nevertheless, again sent out in August, and prevented Villeneuve from effecting a junction with the French fleet at Brest. In consequence of the strong feeling against him at home he demanded a court-martial. This was held on the 23d of December, and resulted in a severe reprimand of the vice-admiral for not having done his utmost to renew the engagement, at the same time acquitting him both of cowardice and disaffection. False expectations had been raised in England by the mutilation of his despatches, and of this he indignantly complained in his defence. The tide of feeling, however, turned again; and in 1815, by way of public testimony to his services, and of acquittal of the charge made against him, he was appointed commander of Portsmouth. He died at Holt, near Bishop's Waltham, in Hampshire, August 31, 1818.

lonia; but in 1651 he entered the church, and from that period wrote nothing but spectacular plays for representation at court, and the religious pieces known as *Autos Sacramentales.* He received various ecclesiastical preferments from Philip IV., and prolonged his days in wealth and honour until his death on May 25, 1681. Very few traits of his personal character have been preserved, and little else can be extracted from the sonorous eulogium of his friend and biographer Vera Tassis than that he was held in esteem for gravity, urbanity, and modesty. A surer testimony to his character is the spirit of his works, which are animated throughout by a lofty ideal of honour and religion according to the conceptions of his age and country, and are wholly free from the usual impurity of the stage. He must evidently have been a highly accomplished man, possessed of a large stock of erudition.

The entire number of pieces comprised in Hartzenbusch's edition of Calderon, which does not include the *autos sacramentales,* is 122. There are 72 *autos.* It is of course impossible to notice here more than a fraction of this prodigious mass of dramatic poetry. We shall briefly characterize the classes under which it admits of being distributed, adducing a few of the more remarkable dramas as representatives of the whole, and following in the main the admirable arrangement of Schack.

1. *Religious Dramas.*—Of these Schack reckons sixteen, including *The Statue of Prometheus* and *Life is a Dream.* This division comprises some of Calderon's most famous pieces, in particular *The Wonder-working Magician,* in which the brilliancy of his poetical imagination is displayed to the fullest extent, and by Shelley's translation of which he is hitherto best known in England. The subject—the voluntary surrender of a human soul to the Evil One—offers striking analogies and equally strong contrasts to Goethe's *Faust.* The comparison of the two pieces is most instructive, and most forcibly attests the vast progress in depth of thought and complexity of emotion of the modern over the mediæval world. *The Devotion of the Cross* is another of the most remarkable pieces of this class, rich in poetical beauties, and exhibiting Catholic antinomianism in its most unmitigated form. There is a deeper vein of thought in *Life is a Dream,* in which the poet is comparatively free from ecclesiastical influences, and which is also one of his most striking and original productions. *The Constant Prince,* founded on Don Ferdinand of Portugal's captivity, is the very flower of Spanish religion, courtesy, and chivalry, and, like *Life is a Dream,* is an excellent acting play. *The Schism of England* and *The Dayspring in Copacavana,* apart from their great poetical merits, are interesting as indications of the national feeling with regard to nearly contemporary events.

2. Nineteen of Calderon's dramas are classed as historical tragedies. These generally exhibit his talent for effective theatrical situation in the most advantageous light; but in psychological depth and truth he is far behind the great dramatic masters of other countries. The most celebrated of these pieces are founded on incidents in Spanish and Portuguese history, from the posthumous coronation of Iñez de Castro to the heart-rending story of *Gomez Arias's Leman,* and the powerful domestic tragedy of the *Alcalde of Zalamea,* which displays more individuality in the delineation of personal character than is usual with him. Nowhere can a fuller insight be obtained into the peculiarities of the Spanish character and the national ideal while the nation was still a great Catholic and Crusading power. Calderon's treatment of historical fact, it need hardly be said, is frequently as free as Shakspeare's. The most remarkable of his historical plays, whose plots are not derived from the history of his own country, are *No Monster like Jealousy,* a most powerful tragedy on the story of Herod and Mariamne; *The Locks of Absalom,* so greatly admired by Shelley; and *Zenobia the Great.*

3. The subjects of twenty-four of Calderon's pieces are derived from mythology, chivalric romance, or novels. Most of these are merely spectacular, affording little scope for strictly dramatic power, but dazzling from the opulence of the poet's invention, and the sweetness and variety of his versification. He has here given his imagination the freest rein, and is nowhere more truly himself. *No Magic like Love,* a play on the story of Circe; *Echo and Narcissus;* and *The Bridge of Mantible* may be cited as characteristic examples.

4. Sixteen romantic dramas, generally melodramas or tragi-comedies, form the transition from Calderon's tragic to his comic theatre. None of his plays are more distinguished for ingenuity of conception and grace of style. *The Loud Secret* is perhaps the most celebrated, but the rest are of hardly inferior merit.

5. We now come to Calderon's comedies of intrigue, the so-called "comedies of cloak and sword," his delineations of the manners of his day, and of the actual human life around him. His range is an exceedingly limited one in comparison with that of the English dramatists. It hardly transcends the sphere of ordinary good society,—the valets and other representatives of the lower orders being for the most part merely conventional types. The motive of his pieces, moreover, seldom comprehends more than the two prime factors of love and jealousy. Within these limits, however, his perception is commonly correct, and his characters are depicted with more individuality and subtlety than in his more serious pieces. Even his high-flown strain of chivalric sentiment and his punctilious formality correspond to fact. They are artificial indeed, but not affected, for they actually represent the ideal of the best contemporary society, and represent the Spanish cavalier, if not precisely as he was, yet as he wished to be esteemed. The capital merit of these pieces, however, is the prodigious ingenuity of the plots, and the fertility of invention by which our attention is kept continually on the stretch. Calderon's expedients are inexhaustible; every fresh incident surprises, and none appears capricious or unnatural. Twenty-five plays are included under this head. *The Fairy Lady* and *'Tis ill keeping a House with Two Doors* are perhaps the most generally known; all however are nearly upon a level.

6. *Autos Sacramentales.*—A volume might be written upon this most peculiar of all the forms of the modern European drama. We can only describe it here as a development of the mystery or miracle play of the Middle Ages, designed like it for public representation on some specified religious occasion, and falling like it into two classes, the strictly Biblical play, of which Calderon's *Brazen Serpent* is an instance, and the religious allegory. The latter is Calderon's characteristic department, and nothing can surpass the boldness and quaintness of his personifications. Man, the World, Guilt, the Morning Star, the Synagogue, and Apostacy figure, for example, among his innumerable *dramatis personæ.* The riches of his invention and his diction are nowhere more abundant; but the profoundness of his philosophy and theology have been greatly over-estimated by writers of his own religious communion.

7. *Minor Pieces.*—Calderon also composed numerous farces, interludes, and other brief occasional pieces, the greater part of which are lost.

Calderon received the Spanish drama from his predecessors in a flourishing condition, exhausted, in conjunction with his numerous gifted contemporaries, every phase of which it allowed, and left it at his death in a condition of total decay. His retirement from the theatre in middle

life was probably occasioned by the conviction that it admitted of no further development. In his relation to his predecessors he appears as an innovator, chiefly in the simplification of metrical forms. Though at least half of each of his plays is still in complete rhyme, he nevertheless resorts to assonances more liberally than his forerunners. If, on the one hand, this brings him nearer to the language of reality, it on the other sometimes betrays him into verbosity. In his earlier pieces the exuberance of his genius, and the example of the popular lyrical poets of the day, tempted him into conceits and extravagances of diction which are less apparent in his later works. He yet has more fire and colour than any other of the Spanish dramatists, and may be described as the one among them in whom the Oriental element is most largely developed. He shares with his rivals the reproach of repetition, of calculated stage effect, and of stereotyped forms of expression, which become at length mere convention and surplusage. The peculiarity of the form of composition cultivated by Calderon renders it difficult to assign his relative rank among poets of the first class. The Spanish drama is a creation *sui generis*, and all attempts at a comparison between it and other theatrical forms must be futile for want of a common measure. The art of Calderon attains its purpose not less completely than that of Shakespeare or Sophocles; all that can be said in its disparagement is that this purpose is less elevated. It falls below the art of Greece, inasmuch as it makes no pretension to represent the ideal either of divinity or of manhood; and below the art of Shakespeare, inasmuch as, instead of offering a mirror to universal nature, it is restricted to the representation or poetic expression of a temporary and accidental phase of manners. It is the most perfect embodiment conceivable of all the romantic and chivalrous elements of Spanish national life; there is not, perhaps, such another example in literature of the wonderful power of poetry to eliminate all baser matter, and present the innermost idea of a society in untarnished brightness. Calderon is also the most perfect representative of the state of feeling induced by unconditional allegiance to the Catholic Church, at the critical moment when the scales of faith and knowledge are yet in equilibrium. Great Catholic poets may yet arise, with even more than Calderon's depth of conviction, but none can again enjoy Calderon's serenity. There is no disturbing element in his world, either of innovation or of resistance; he is everything which by theory a consummate Catholic poet ought to be. It is therefore but logical that he should be set up as the rival of Shakespeare by the partisans of the mediæval revival, of whom Frederick Schlegel is the most eminent literary representative. It would be a waste of time to contrast the conventional uniformity of his pieces, reducible to five or six types at most, with Shakespeare's infinite variety; the faint individualization of his characters with Shakespeare's miraculous subtlety; his class prejudices with Shakespeare's universal sympathy; his stereotyped cast of thought with Shakespeare's comprehensive wisdom. It is enough to remark, that greatly as he is admired and widely as he is read, he has not contributed a single appreciable element to the literature of any country but his own, while Shakespeare has revolutionized the taste of Europe. His relation to his contemporaries is also different from Shakespeare's. Shakespeare is a sun among stars; Calderon the brightest star of a group. We shall render him most justice, not by instituting a vain parallel with Shakespeare, or even Goethe, but by regarding those qualities which he necessarily has in common with all poetical dramatists. In these respects it is impossible to praise him too highly Nothing can surpass the fertility, ingenuity, and consistency of his constructive faculty on the one hand, or the affluence of his imagery and melody of his versification on the other. The poet and the playwright are happily combined in him; the development of his plots holds the spectator in suspense from first to last, and the diction, except in designedly comic passages, seldom lapses below the pitch of dignified and exquisite poetry. Even the extravagance of his hyperboles appears almost natural amid the general torrent of impassioned feeling. The interminable length of many of his speeches is certainly a fault, and is partly attributable to the fluency and facility of his metre. If we regard him as a tragic poet, we must allow him power, restricted by the absence of any philosophical view of human nature or destiny. As a comic poet he excels in the *vis comica* of situation; but his dialogue is more remarkable for vivacity than humour. His proper and peculiar sphere is that of the fancifully poetical. His inventiveness is here equal to any feat of construction, and his imagination to any opulence of adornment. After Shakespeare and Aristophanes, no dramatist has understood so well how to transport his reader or spectator to an ideal world.

Calderon's metrical forms, although, as already stated, less rich and intricate than those of the earlier Spanish dramatists, are nevertheless a great obstacle to his being adequately translated. No language but the German, in fact, is adapted to render him. Gries's version in that language is very celebrated. Schlegel and Schack have rendered some plays very well; and the *autos* have been translated by Lorinser. Shelley's version of some scenes of the *Wonder-working Magician* is incomparably the best English interpretation, and no reproduction in our language will ever be perfectly successful that does not proceed upon his principle of intermingling blank verse with irregular lyrical metres. Mr Fitzgerald and Mr D. F. M'Carthy, two excellent translators, have erred,—the former by resorting to blank verse entirely, the latter by discarding it altogether. Mr Fitzgerald's version is too English, and Mr M'Carthy's too Spanish; the peculiar delicacy of the assonant rhyme, which he has endeavoured to preserve throughout, is entirely imperceptible in our language. Mr Fitzgerald has rendered six plays, and Mr M'Carthy eleven. There is perhaps no more congenial field for a writer of a poetical temperament than the translation of Calderon.

The chronology of Calderon's pieces is unsettled, but much has been done to adjust it. Many of them were printed during his life, but the first collective edition was that published in 1685 by his friend Vera Tassis. It is not quite complete, and some plays, including most of the author's dramatic trifles, are irremediably lost. The best edition is that by Hartzenbusch in Aribau's *Biblioteca de Autores Españoles* (4 vols., Madrid, 1848–50). It does not contain the *autos*, which were published at Madrid in 1717 and in 1759–60. There is also a good edition by Keil (Hamburg, 1827–30). Accounts of Calderon will be found in Bouterwek, Ticknor, and other historians of Spanish literature; but the best and fullest is that by Schack in his *Geschichte der dramatischen Literatur und Kunst in Spanien*, vol. iii. (Berlin, 1846.) (R. G.)

CALDERWOOD, David (1575–1650), an historian of the Church of Scotland, was born in 1575. He was educated at Edinburgh, where he took the degree of M.A. in 1593. About 1604 he became minister of Crailing, near Jedburgh, and he speedily began to take part in the ecclesiastical proceedings of that period, and was conspicuous for his resolute opposition to the introduction of Episcopacy. In 1617, while James was in Scotland, a Remonstrance which had been drawn up by the Presbyterian clergy was placed in Calderwood's hands. He was summoned to St Andrews and examined before the king, but neither threats nor promises could make him yield, and deliver up the roll of signatures to the Remonstrance. He was deprived of his charge, committed to prison at St Andrews, and afterwards removed to Edinburgh. The privy council, which long exercised an undefined and despotic jurisdiction, ordained him to be banished from the kingdom for refusing to

acknowledge the sentence of the High Commission. On giving security to banish himself from the kingdom before the ensuing Michaelmas, and not to return without the royal licence, he was released from prison. He accompanied Lord Cranstoun to Carlisle, where that nobleman presented a petition in his favour to the king; but it was followed by no beneficial result. The subsequent application of Lord Cranstoun to the privy-council, and to the bishops, was attended with no better success. He lingered in Scotland, publishing a few tracts, till the 27th of August 1619, when he sailed for Holland. Where he chiefly resided in that country we are not informed, but Bishop Guthry states, that "in the time of his exile he had seen the wild follies of the English Brownists in Arnheim and Amsterdam." During his residence in Holland he published various works, and, among the rest, his *Altare Damascenum*. At one period his enemies supposed him to be dead; and he has recorded a very extraordinary attempt to impose upon the world a recantation fabricated in his name. Calderwood appears to have returned to Scotland in 1624, and he was soon afterwards appointed minister of Pencaitland, in the county of Haddington. During the remainder of his life he continued to take an active part in the affairs of the church, and he introduced in 1649 the practice, now confirmed by long usage, of dissenting from the decision of the Assembly, and requiring the protest to be entered in the record. His last years were devoted to the preparation of a *History of the Church of Scotland*. In 1648 the General Assembly urged him to complete the work he had designed, and voted him a yearly pension of £800. He left behind him an historical work of great extent and of great value, not indeed as a masterly composition, but as a storehouse of authentic materials for history. An abridgment, which appears to have been prepared by himself, was published after his death. An excellent edition of the complete work was published by the Wodrow Society, 8 vols. 1842–49. The manuscript, which belonged to General Calderwood Durham, was presented to the British Museum. A copy, transcribed under the inspection of Wodrow, is among the archives of the church; another belongs to the library of the university of Glasgow; and, as Dr M'Crie has stated, "in the Advocates' Library, besides a complete copy of that work, there is a folio volume of it, reaching to the end of the year 1572. It was written in 1634, and has a number of interlineations and marginal alterations, differing from the other copies, which, if not made by the author's own hand, were most probably done under his eye." Calderwood died at Jedburgh on the 29th of October 1650, aged seventy-five. He appears to have been a man of unbending integrity, fearless in maintaining his opinions, and uniformly consistent in his professions; but as human virtues are never perfect, his decision of character had some tendency to deviate into that obstinacy from which good men are not always exempted.

CALEDONIA, used in general somewhat loosely to denote the northern portion of Britain during the period of the Roman occupation of the island, had originally a more restricted application. It is proposed in this article to give, from a geographical as well as an historical point of view, a brief account of what seems to have been known regarding it in ancient times.

The word *Caledonia* is first met with in the fourth book of Pliny's *Historia Naturalis* (*circa* 77 A.D.), where, in the very meagre notice of Britain, the Caledonian forest (*Caledonia sylva*) is given as the northern boundary of the Roman part of the island. Its next appearance is in the *Agricola* of Tacitus (96 A.D.) Here, both in the brief geographical description of Britain, chaps. x. and xi., and in the account of Agricola's campaigns, chaps. xxv.–xxxviii., Caledonia is unquestionably Britain north of the Firth of Forth. On turning to the geographer Ptolemy (*circa* 120 A.D.), we fail to meet with the term except as the name of one of the many tribes among which he has parcelled out the "Bretannic Island, Albion." To explain this it is not necessary to assume that Ptolemy was ignorant of the wider acceptation in which Caledonia had recently come to be employed among the Romans. It is more reasonable to suppose that, as he avowedly drew the materials for his tables from earlier, chiefly from Tyrian sources, he judged it prudent to follow in the main long-recognized authorities. Yet even in Ptolemy we have an indication either of the importance of the Caledonians among their neighbours or of the occasional use of the word as a general name for all the northern tribes. Twice he gives the Deucaledonian Ocean as bounding Britain on the north, that is, after the necessary correction for his mistake in making the whole of the northern part of the island trend to the east instead of to the north, as washing the shores of modern Scotland on the west. Confused and inaccurate in some respects as the Alexandrian geographer's tables are, they, notwithstanding, contain a surprising amount of information regarding the leading features of the coast-line of Britain, the correctness of much of which can be verified by existing names. His account of the tribes and their towns, especially towards the north, is, as might have been expected, much less definite and trustworthy. In order to be able to give here some notice of the Ptolemaic geography of North Britain, Caledonia may for the moment be regarded as a synonymous term.

Ptolemy's error in turning the northern part of the island to the east has already been noticed. How he was led into it there are no means of determining. One effect of it is to exaggerate greatly the length of the Solway Firth and displace the Hebrides from their true position, as may be seen by referring to certain maps appended to several MSS. of the Geography and given with some editions of it. The error can easily be rectified; and when this is done the outline of the coast will be found to be wonderfully correct.[1] Commencing with the promontory of the Noouantai (Mull of Galloway) in the south-west and proceeding northwards along the shores of the Deucaledonian Ocean, we have in succession the Bay of Rerigonios (Loch Ryan), the Bay of Ouindogara (Ayr), the estuary of the Klota (Clyde), the Bay of Lelaamnonios (Loch Fyne), Cape Epidion (Mull of Kintyre), the outlets of the River Longus (Loch Linnhe ?), outlets of the River Ituos, Bay of O.olsas (Lochalsh?), outlets of the River Nabaios, and Cape Tarouedoum or Orkas (Dunnet Head). Coming down the east coast, said to be washed by the German Ocean, we find Cape Ouirouedroum (Duncansbay Head), Cape Oueroubium (Noss Head ?), the outlets of the River Ila, the High Bank, outlets of the River Loxa, estuary of the Ouarar (Moray Firth), estuary of the Touaisis (Spey ?), outlets of the River Kelnios (Deveron ?), the promontory of the Taizalai (Kinnaird's Head), outlets of the River Deoua (Dee), estuary of the Taoua (Tay), outlets of the River Tina, estuary of the Boderia (Firth of Forth), outlets of the River Alaunos, outlets of the River Ouedra (Tyne ?). On the south, bounded by the Hibernian Ocean, we have the peninsula of the Noouantai (the Rhinns of Galloway), outlets of the River Abraouannos (Luce ?), estuary of the Iena (Cree ?), estuary of the Deoua (Dee), outlets of the River Noouios (Nith), outlets of the Itouna (Eden).

The country is represented as inhabited by the following

[1] The orthography of the names that follow is that of the text of Ptolemy (Wilberg's), and not of the Latin translation. With a few exceptions they are evidently intended to express native terms by means of Greek (perhaps originally Tyrian) characters, and it seems undesirable to obscure them further by presenting them in those of another language

tribes, sixteen in number:—the Noouantai, dwelling under (*i.e.*, east) of the peninsula of the same name (Wigtonshire), their towns Loukopibia and Retigonion; east of them the Selgoouai (along the Solway Firth, and inland), their towns Karbantorigon, Ouxellon (Dumfries?), Korda, Trimontion; still further east, the Otadinoi, probably along the south-east coast, their towns Kouria and Bremenion; and the Damnonioi, occupying apparently the basins of the Clyde, Forth, and Tay (in part), their towns Kolania, Ouandouara (Ayr?), Koria, Alauna (Stirling?), Lindon, Ouiktoria (near Perth); the Kaledonioi, in the district from Loch Fyne to the Moray Firth, with the Caledonian forest to the west of them; eastward the Ouakomagoi (Banff and parts of Moray and Aberdeen), their towns Banatia, Tameia, the Winged Camp, Touaisis; east of these the Taizaloi (part of Aberdeenshire), their town Deouana (Aberdeen), and the Ouenicones (Forfarshire), their town Orrea (Forfar?); while occupying the west of Argyll and Inverness, part of Ross-shire, and the whole of Sutherland and Caithness, were in succession the Epidioi (in Kintyre), Kerones, Kreones, Karnonakai, Karinoi, Kornauioi (Caithness), Decantai, Lougoi, and Smertai. Near the promontory of Orkas were the islands of Okitis and Doumna; north of which lay the Orkades (Orkneys), about thirty in number, and still farther north Thoule (Shetland?).

Ptolemy's description is the only detailed one we have till we come down to the 16th century. It is matter for regret that the *Antonine Itinerary*, so useful an aid to the identification of the Ptolemaic towns in the southern part of the island, does not extend to the north, and that the lists of the anonymous geographer of Ravenna are so corrupt as to be almost useless. About the middle of the last century a new element of confusion was introduced into what was tangled enough previously, by the publication of Bertram's well-known forgery *De Situ Britanniæ*, falsely ascribed to Richard of Cirencester, which being accepted as genuine by Roy, Chalmers, Stuart, and others, has been the means of giving currency to many unfounded notions regarding the nature and extent of the Roman conquests in North Britain.

The written history of Caledonia as well as of the rest of what is now Scotland commences with the warlike operations in Britain of Agricola, the lieutenant of the Emperor Domitian. (See BRITANNIA, p. 353.) In the third year of his command this famous general, who was fortunate enough to have his son-in-law Tacitus as his biographer, determined to attempt the annexation of the northern portion of the island. Accordingly, in 80 A.D., he advanced as far as the estuary of the Taus, or as Wex reads, the Tanaus. Whatever the true reading may be, the supposition that on this occasion Agricola reached the Tay is untenable; though, whether the river referred to be the English Tyne, the Tweed, or the Scotch Tyne, it is impossible to say. The succeeding summer found him as far north as the isthmus formed by the firths of Clota and Bodotria (Clyde and Forth). On it he erected a line of forts, with the intention apparently of making it the northern boundary of the empire in those parts. In the following year he crossed the Clota, and overran additional territory "in that part of Britain which looks towards Ireland." Information having now reached him that the remoter and still unconquered tribes were forming a combination against the Romans, he resolved to anticipate them, and (83 A.D.) carried the war beyond the Bodotria into the country of the Caledonians. That summer an engagement was fought, which, though it resulted in favour of the invaders, taught the Romans that they had no ordinary foe to cope with. On the approach of winter both sides retired to their quarters to make preparations for renewing the struggle. Next season (84) Agricola, on resuming the offensive, found himself confronted by a grand union of all the tribes of Caledonia, under a leader whom Tacitus names Galgacus. The Roman general had previously despatched a fleet to ravage the coast, and on continuing his march northwards, encountered the enemy, upwards of 30,000 strong, near Mount Graupius; for there can be little doubt that this, the reading of Wex and Kritz, ought to be adopted instead of the Grampius of the common editions. The exact locality of the conflict that ensued has been the theme of much profitless controversy; but we shall probably not greatly err in placing it somewhere on the borders of Kincardineshire. General Roy, whose conjecture is usually followed, fixed on Ardoch in Perthshire. A careful study, however, of the whole narrative leads one to look for the field of battle farther north, and nearer the coast. Tacitus, writing on the model of Thucydides and Livy, has put into the mouth of each leader, on the eve of the engagement, a speech of his own composition, in which he describes the feelings that may be supposed to have actuated the hostile armies. That ascribed to Galgacus is a splendid specimen of polished sarcasm, mixed with impassioned appeals to the patriotism of his hearers. Might, however, prevailed over right, and the Caledonians were defeated with a loss of 10,000 men. Agricola, now thinking he had pushed his conquests far enough, made no attempt to pursue his beaten foe, but at once led his army back to the territory of the Boresti (*al.* Horesti), whose name is probably preserved in the modern Forfar. Here he gave orders to the commander of his fleet to sail round the island, a feat which the latter accomplished. Soon after he himself was recalled to Rome by his jealous master.

Notwithstanding Agricola's success, the Romans seem to have been quickly obliged to abandon part of their conquests, for in less than forty years (129 A.D.) Hadrian's wall, which ran from the Tyne to the Solway, became the northern limits of their empire in Britain. About twenty years later a second Agricola appeared in the person of Lollius Urbicus, the lieutenant of Antoninus Pius. Almost nothing is known of his actions, but he seems to have once more carried the arms of Rome to the Clyde and Forth, if not beyond them, and to have erected on the line of Agricola's forts the more substantial work now known by the name of the emperor he served (see ANTONINUS, WALL OF). The natives must soon have recovered the lost ground; but scarcely anything is known henceforth of the state of affairs in the north till 208, when, if we may trust the historian Dion Cassius, as abridged by Xiphiline, the Emperor Severus determined to attempt the subjugation of the whole island. At that time the two most powerful tribes of North Britain were the Mæatæ, close to Hadrian's Wall, and the Caledonians beyond them. Protected by their native fastnesses, the latter offered him such a resistance that, without being able to bring them to a decisive engagement, he lost through disease, fatigue, and the sword, no fewer, it is said, than 50,000 men. Having reached what is termed the northern extremity of the island, but which was in all likelihood merely the northern coast of Aberdeenshire, Severus retreated southwards in a very feeble state of health, partly induced by the fatigues he had undergone. A league formed the next year between the Caledonians and the Mæatæ, both of whom had already cast off his authority, led him to make preparations for a new campaign, with the avowed determination of extirpating the whole race. In the midst of these, however, he died at York in 210.

For a whole century afterwards the ancient writers are almost silent regarding Caledonia. In the year 310 we hear for the first time of the Picts; and in 367 Theodosius, an able Roman general, was sent into Britain by Valentinian I. to defend the Britons of the south against the

attacks of the men of the north, represented by Ammianus Marcellinus as being the Picts divided into two tribes (the Dicaledones and the Vecturiones), the Saxons, the Attacotti, and the Scots. He was so far successful that the countries between the walls of Hadrian and Antoninus became yet again a subjected province, named Valentian by Theodosius, in honour of the emperor,—a conquest, however, which can have lasted but a brief period. Henceforth, if we except the effusions of the poet Claudian, the scanty notices of Britain to be met with during several succeeding centuries present the same sad tale of sufferings inflicted on the now effeminate Britons of the south by their warlike neighbours, till at length the settlement of large bodies of Saxons in England changed the aspect of affairs.

The etymology of the word Caledonia has been variously given. *Celydd* (in Welsh, a woody shelter) is the popular derivation; but Isaac Taylor (*Words and Places*, p. 44) thinks the word may possibly contain the root *gael*, and if so, the Caledonians would be the Gaels of the duns or hills. Equally obscure are the ethnological relations of the people, the most probable opinion being that which regards them as belonging to the British branch of the great Celtic family. A casual inference, hazarded by Tacitus (*Agricola*, chap. xi.), that the red hair and large limbs of the inhabitants of Caledonia point clearly to a German origin, must not be pressed too far. There were probably even in his day Teutonic settlements along our eastern and northern shores, but it seems too much to assume that that race was the dominant one north of the Forth. It is a still more doubtful question to what race the Picts belonged. But the discussion of these and other points belongs to the history of SCOTLAND (*q.v.*) (See *Claudii Ptolemæi Geographia*, ed. Wilberg, Essendiæ, 1838; Roy's *Military Antiquities of the Romans in North Britain*, London, 1793; Burton's *History of Scotland*, vol. i., Edin. 1867.) (J. M'D.)

CALENBERG, or KALENBERG, a former principality of Hanover, which was traversed by the Weser and the Leine, and had an area of about 1050 square miles. It derived its name from an ancient castle, now in ruins. In the Middle Ages it belonged to Lüneburg, and after passing from one branch to another of the house of Brunswick, it came, in 1705, to Ernst August, electoral prince of Hanover.

CALENDAR

A CALENDAR is a method of distributing time into certain periods adapted to the purposes of civil life, as hours, days, weeks, months, years, &c.

Of all the periods marked out by the motions of the celestial bodies, the most conspicuous, and the most intimately connected with the affairs of mankind, are the *solar day*, which is distinguished by the diurnal revolution of the earth and the alternation of light and darkness, and the *solar year*, which completes the circle of the seasons. But in the early ages of the world, when mankind were chiefly engaged in rural occupations, the phases of the moon must have been objects of great attention and interest,—hence the *month*, and the practice adopted by many nations of reckoning time by the motions of the moon, as well as the still more general practice of combining lunar with solar periods. The solar day, the solar year, and the lunar month, or lunation, may therefore be called the *natural* divisions of time. All others, as the hour, the week, and the civil month, though of the most ancient and general use, are only arbitrary and conventional.

DAY.—The true solar day is the interval of time which elapses between two consecutive returns of the same terrestrial meridian to the sun. By reason of the inclined position of the ecliptic, and the unequal progressive motion of the earth in its orbit, it is not always of the same absolute length. But as it would be hardly possible, in the artificial measurement of time, to have regard to this small inequality which is besides constantly varying, the *mean solar day* is employed for all civil purposes. This is the time in which the earth *would* make one revolution on its axis, as compared with the sun, if the earth moved at an equable rate in the plane of the equator. The mean solar day is therefore a result of computation, and is not marked precisely by any astronomical phenomenon; but its difference from the true solar or apparent day is so small as to escape ordinary observation.

The subdivision of the day into twenty-four parts, or hours, has prevailed since the remotest ages, though different nations have not agreed either with respect to the epoch of its commencement or the manner of distributing the hours. Europeans in general, like the ancient Egyptians, place the commencement of the civil day at midnight, and reckon twelve morning hours from midnight to mid day, and twelve evening hours from mid-day to midnight. Astronomers, after the example of Ptolemy, regard the day as commencing with the sun's culmination, or noon, and find it most convenient for the purposes of computation to reckon through the whole twenty-four hours. Hipparchus reckoned the twenty-four hours from midnight to midnight. Some nations, as the ancient Chaldeans and the modern Greeks, have chosen sunrise for the commencement of the day; others, again, as the Italians and Bohemians, suppose it to commence at sunset. In all these cases the beginning of the day varies with the seasons at all places not under the equator. In the early ages of Rome, and even down to the middle of the 5th century after the foundation of the city, no other divisions of the day were known than sunrise, sunset, and mid-day, which was marked by the arrival of the sun between the Rostra and a place called Græcostasis, where ambassadors from Greece and other countries used to stand. The Greeks divided the natural day and night into twelve equal parts each, and the hours thus formed were denominated *temporary hours*, from their varying in length according to the seasons of the year. The hours of the day and night were of course only equal at the time of the equinoxes. The whole period of day and night they called νυχθήμερον.

WEEK.—The week is a period of seven days, having no reference whatever to the celestial motions,—a circumstance to which it owes its unalterable uniformity. Although it did not enter into the calendar of the Greeks, and was not introduced at Rome till after the reign of Theodosius, it has been employed from time immemorial in almost all eastern countries; and as it forms neither an aliquot part of the year nor of the lunar month, those who reject the Mosaic recital will be at a loss, as Delambre remarks, to assign to it an origin having much semblance of probability. It might have been suggested by the phases of the moon, or by the number of the planets known in ancient times, an origin which is rendered more probable from the names universally given to the different days of which it is composed. In the Egyptian astronomy, the order of the planets, beginning with the most remote, is Saturn, Jupiter, Mars, the Sun, Venus, Mercury, the Moon. Now, the day being divided into twenty-four hours, each hour was consecrated to a particular planet, namely, one to Saturn, the following to Jupiter, the third to Mars, and so on according to the above order; and the day received the name

planet which presided over its first hour. If, then, the first hour of a day was consecrated to Saturn, that planet would also have the 8th, the 15th, and the 22nd hour; the 23rd would fall to Jupiter, the 24th to Mars, and the 25th, or the first hour of the second day, would belong to the Sun. In like manner the first hour of the 3rd day would fall to the Moon, the first of the 4th day to Mars, of the 5th to Mercury, of the 6th to Jupiter, and of the 7th to Venus. The cycle being completed, the first hour of the 8th day would return to Saturn, and all the others succeed in the same order. According to Dio Cassius, the Egyptian week commenced with Saturday. On their flight from Egypt, the Jews, from hatred to their ancient oppressors, made Saturday the last day of the week.

The English names of the days are derived from the Saxon. The ancient Saxons had borrowed the week from some Eastern nation, and substituted the names of their own divinities for those of the gods of Greece. In legislative and justiciary acts the Latin names are still retained.

Latin.	English.	Saxon
Dies Solis.	Sunday.	Sun's day.
Dies Lunæ.	Monday.	Moon's day.
Dies Martis.	Tuesday.	Tiw's day.
Dies Mercurii.	Wednesday.	Woden's day.
Dies Jovis.	Thursday.	Thor's day.
Dies Veneris	Friday.	Friga's day.
Dies Saturni.	Saturday.	Seterne's day.

MONTH.—Long before the exact length of the year was determined, it must have been perceived that the synodic revolution of the moon is accomplished in about 29½ days. Twelve lunations, therefore, form a period of 354 days, which differs only by about 11¼ days from the solar year. From this circumstance has arisen the practice, perhaps universal, of dividing the year into twelve *months*. But in the course of a few years the accumulated difference between the solar year and twelve lunar months would become considerable, and have the effect of transporting the commencement of the year to a different season. The difficulties that arose in attempting to avoid this inconvenience induced some nations to abandon the moon altogether, and regulate their year by the course of the sun. The month, however, being a convenient period of time, has retained its place in the calendars of all nations; but, instead of denoting a synodic revolution of the moon, it is usually employed to denote an arbitrary number of days approaching to the twelfth part of a solar year.

Among the ancient Egyptians the month consisted of thirty days invariably; and in order to complete the year, five days were added at the end, called supplementary days. They made use of no intercalation, and by losing a fourth of a day every year, the commencement of the year went back one day in every period of four years, and consequently made a revolution of the seasons in 1461 years. Hence 1461 Egyptian years are equal to 1460 Julian years of 365¼ days each. This year is called *vague*, by reason of its commencing sometimes at one season of the year, and sometimes at another.

The Greeks divided the month into three decades, or periods of ten days,—a practice which was imitated by the French in their unsuccessful attempt to introduce a new calendar at the period of the Revolution. This division offers two advantages: the first is, that the period is an exact measure of the month of thirty days; and the second is, that the number of the day of the decade is connected with and suggests the number of the day of the month. For example, the 5th of the decade must necessarily be the 5th, the 15th, or the 25th of the month; so that when the day of the decade is known, that of the month can scarcely be mistaken. In reckoning by weeks, it is necessary to keep in mind the day of the week on which each month begins.

The Romans employed a division of the month and a method of reckoning the days which appear not a little extraordinary, and must, in practice, have been exceedingly inconvenient. As frequent allusion is made by classical writers to this embarrassing method of computation, which is carefully retained in the ecclesiastical calendar, we here give a table showing the correspondence of the Roman months with those of modern Europe.

Days of the Month.	March. May. July. October.	January. August. December.	April. June. September. November.	February.

Instead of distinguishing the days by the ordinal numbers first, second, third, &c., the Romans counted *backwards* from three fixed epochs, namely, the *Calends*, the *Nones*, and the *Ides*. The Calends (or Kalends) were invariably the first day of the month, and were so denominated because it had been an ancient custom of the pontiffs to call the people together on that day, to apprize them of the festivals, or days that were to be kept sacred during the month. The Ides (from an obsolete verb *iduare*, to divide) were at the middle of the month, either the 13th or the 15th day; and the Nones were the *ninth* day before the Ides, counting inclusively. From these three terms the days received their denomination in the following manner:—Those which were comprised between the Calends and the Nones were called *the days before the Nones;* those between the Nones and the Ides were called *the days before the Ides;* and, lastly, all the days after the Ides to the end of the month were called *the days before the Calends* of the succeeding month. In the months of March, May, July, and October, the Ides fell on the 15th day, and the Nones consequently on the 7th; so that each of these months had six days named from the Nones. In all the other months the Ides were on the 13th and the Nones on the 5th; consequently there were only four days named from the Nones. Every month had eight days named from the Ides. The number of days receiving their denomination from the Calends depended on the number of days in the month and the day on which the Ides fell. For example, if the month contained 31 days, and the Ides fell on the 13th, as was the case in January, August, and December, there would remain 18 days after the Ides, which, added

to the first of the following month, made 19 days of Calends. In January, therefore, the 14th day of the month was called the *nineteenth before the Calends of February* (counting inclusively), the 15th was the 18th before the Calends, and so on to the 30th, which was called the third before the Calends (*tertio Calendas*), the last being the second of the Calends, or the day before the Calends (*pridie Calendas*).

YEAR.—The year is either astronomical or civil. The solar astronomical year is the period of time in which the earth performs a revolution in its orbit about the sun, or passes from any point of the ecliptic to the same point again; and consists of 365 days 5 hours 48 min. and 46 sec. of mean solar time. The civil year is that which is employed in chronology, and varies among different nations, both in respect of the season at which it commences and of its subdivisions. When regard is had to the sun's motion alone, the regulation of the year, and the distribution of the days into months, may be effected without much trouble; but the difficulty is greatly increased when it is sought to reconcile solar and lunar periods, or to make the subdivisions of the year depend on the moon, and at the same time to preserve the correspondence between the whole year and the seasons.

Of the Solar Year.—In the arrangement of the civil year, two objects are sought to be accomplished,—first, the equable distribution of the days among twelve months; and secondly, the preservation of the beginning of the year at the same distance from the solstices or equinoxes. Now, as the year consists of 365 days and a fraction, and 365 is a number not divisible by 12, it is impossible that the months can all be of the same length, and at the same time include all the days of the year. By reason also of the fractional excess of the length of the year above 365 days, it likewise happens that the years cannot all contain the same number of days if the epoch of their commencement remains fixed; for the day and the civil year must necessarily be considered as beginning at the same instant; and therefore the extra hours cannot be included in the year till they have accumulated to a whole day. As soon as this has taken place, an additional day must be given to the year.

The civil calendar of all European countries has been borrowed from that of the Romans. Romulus is said to have divided the year into ten months only, including in all 304 days, and it is not very well known how the remaining days were disposed of. The ancient Roman year commenced with March, as is indicated by the names September, October, November, December, which the last four months still retain. July and August, likewise, were anciently denominated Quintilis and Sextilis, their present appellations having been bestowed in compliment to Julius Cæsar and Augustus In the reign of Numa two months were added to the year, January at the beginning, and February at the end; and this arrangement continued till the year 452 B.C., when the Decemvirs changed the order of the months, and placed February after January. The months now consisted of twenty-nine and thirty days alternately, to correspond with the synodic revolution of the moon, so that the year contained 354 days; but a day was added to make the number odd, which was considered more fortunate, and the year therefore consisted of 355 days. This differed from the solar year by ten whole days and a fraction; but, to restore the coincidence, Numa ordered an additional or intercalary month to be inserted every second year between the 23rd and 24th of February, consisting of twenty-two and twenty-three days alternately, so that four years contained 1465 days, and the mean length of the year was consequently 366¼ days. The additional month was called *Mercedinus* or *Mercedonius*, from *merces*, wages, probably because the wages of workmen and domestics were usually paid at this season of the year. According to the above arrangement, the year was too long by one day, which rendered another correction necessary. As the error amounted to twenty-four days in as many years, it was ordered that every third period of eight years, instead of containing four intercalary months, amounting in all to ninety days, should contain only three of those months, consisting of twenty-two days each. The mean length of the year was thus reduced to 365¼ days; but it is not certain at what time the octennial periods, borrowed from the Greeks, were introduced into the Roman calendar, or whether they were at any time strictly followed. It does not even appear that the length of the intercalary month was regulated by any certain principle, for a discretionary power was left with the pontiffs, to whom the care of the calendar was committed, to intercalate more or fewer days according as the year was found to differ more or less from the celestial motions. This power was quickly abused to serve political objects, and the calendar consequently thrown into confusion. By giving a greater or less number of days to the intercalary month, the pontiffs were enabled to prolong the term of a magistracy, or hasten the annual elections; and so little care had been taken to regulate the year, that, at the time of Julius Cæsar, the civil equinox differed from the astronomical by three months, so that the winter months were carried back into autumn, and the autumnal into summer.

In order to put an end to the disorders arising from the negligence or ignorance of the pontiffs, Cæsar abolished the use of the lunar year and the intercalary month, and regulated the civil year entirely by the sun. With the advice and assistance of Sosigenes, he fixed the mean length of the year at 365¼ days, and decreed that every fourth year should have 366 days, the other years having each 365. In order to restore the vernal equinox to the 25th of March, the place it occupied in the time of Numa, he ordered two extraordinary months to be inserted between November and December in the current year, the first to consist of thirty-three, and the second of thirty-four days. The intercalary month of twenty-three days fell into the year of course, so that the ancient year of 355 days received an augmentation of ninety days; and the year on that occasion contained in all 445 days. This was called the last year of confusion. The first Julian year commenced with the 1st of January of the 46th before the birth of Christ, and the 708th from the foundation of the city.

In the distribution of the days through the several months, Cæsar adopted a simpler and more commodious arrangement than that which has since prevailed. He had ordered that the first, third, fifth, seventh, ninth, and eleventh months, that is January, March, May, July, September, and November, should have each thirty-one days, and the other months thirty, excepting February, which in common years should have only twenty-nine, but every fourth year thirty days. This order was interrupted to gratify the vanity of Augustus, by giving the month bearing his name as many days as July, which was named after the first Cæsar. A day was accordingly taken from February and given to August; and in order that three months of thirty-one days might not come together, September and November were reduced to thirty days, and thirty-one given to October and December. For so frivolous a reason was the regulation of Cæsar abandoned, and a capricious arrangement introduced, which it requires some attention to remember.

The additional day which occurred every fourth year ... the shortest month, and

was inserted in the calendar between the 24th and 25th day. February having then twenty-nine days, the 25th was the 6th of the calends of March, *sexto calendas;* the preceding, which was the additional or intercalary day, was called *bis-sexto calendas*,—hence the term *bissextile*, which is still employed to distinguish the year of 366 days. The English denomination of *leap-year* would have been more appropriate if that year had differed from common years in *defect*, and contained only 364 days. In the modern calendar the intercalary day is still added to February, not, however, between the 24th and 25th, but as the 29th.

The regulations of Cæsar were not at first sufficiently understood; and the pontiffs, by intercalating every third year instead of every fourth, at the end of thirty-six years had intercalated twelve times, instead of nine. This mistake having been discovered, Augustus ordered that all the years from the thirty-seventh of the era to the forty-eighth inclusive should be common years, by which means the intercalations were reduced to the proper number of twelve in forty-eight years. No account is taken of this blunder in chronology; and it is tacitly supposed that the calendar has been correctly followed from its commencement.

Although the Julian method of intercalation is perhaps the most convenient that could be adopted, yet, as it supposes the year too long by 11 minutes 14 seconds, it could not without correction very long answer the purpose for which it was devised, namely, that of preserving always the same interval of time between the commencement of the year and the equinox. Sosigenes could scarcely fail to know that this year was too long; for it had been shown long before, by the observations of Hipparchus, that the excess of 365¼ days above a true solar year would amount to a day in 300 years. The real error is indeed more than double of this, and amounts to a day in 128 years; but in the time of Cæsar the length of the year was an astronomical element not very well determined. In the course of a few centuries, however, the equinox sensibly retrograded towards the beginning of the year. When the Julian calendar was introduced, the equinox fell on the 25th of March. At the time of the Council of Nice, which was held in 325, it fell on the 21st; and when the reformation of the calendar was made in 1582, it had retrograded to the 11th. In order to restore the equinox to its former place, Pope Gregory XIII. directed ten days to be suppressed in the calendar; and as the error of the Julian intercalation was now found to amount to three days in 400 years, he ordered the intercalations to be omitted on all the centenary years excepting those which are multiples of 400. According to the Gregorian rule of intercalation, therefore, every year of which the number is divisible by four without a remainder, is a leap year, excepting the centurial years, which are only leap years when divisible by four after omitting the two ciphers. Thus 1600 was a leap year, but 1700, 1800, and 1900 are common years; 2000 will be a leap year, and so on.

As the Gregorian method of intercalation has been adopted in all Christian countries, Russia excepted, it becomes interesting to examine with what degree of accuracy it reconciles the civil with the solar year. According to the best determinations of modern astronomy (Le Verrier's *Solar Tables*, Paris, 1858, p. 102), the mean geocentric motion of the sun in longitude, from the mean equinox during a Julian year of 365·25 days, the same being brought up to the present date, is $360° + 27''\cdot685$. Thus the mean length of the solar year is found to be $\frac{360°}{360° + 27''\cdot685} \times 365\cdot25 = 365\cdot2422$ days, or 365 days 5 hours 48 min. 46 sec. Now the Gregorian rule gives 97 intercalations in 400 years; 400 years therefore contain $365 \times 400 + 97$, that is, 146,097 days; and consequently one year contains 365·2425 days, or 365 days 5 hours 49 min. 12 sec. This exceeds the true solar year by 26 seconds, which amount to a day in 3323 years. It is perhaps unnecessary to make any formal provision against an error which can only happen after so long a period of time; but as 3323 differs little from 4000, it has been proposed to correct the Gregorian rule by making the year 4000 and all its multiples common years. With this correction the rule of intercalation is as follows:—

Every year the number of which is divisible by 4 is a leap year, excepting the last year of each century, which is a leap year only when the number of the century is divisible by 4; but 4000, and its multiples, 8000, 12,000, 16,000, &c. are common years. Thus the uniformity of the intercalation, by continuing to depend on the number four, is preserved, and by adopting the last correction the commencement of the year would not vary more than a day from its present place in two hundred centuries.

In order to discover whether the coincidence of the civil and solar year could not be restored in shorter periods by a different method of intercalation, we may proceed as follows:—The fraction 0·2422, which expresses the excess of the solar year above a whole number of days, being converted into a continued fraction, becomes

$$\cfrac{1}{4+\cfrac{1}{7+\cfrac{1}{1+\cfrac{1}{3+\cfrac{1}{4+\cfrac{1}{1+\text{, \&c.}}}}}}}$$

which gives the series of approximating fractions,

$$\frac{1}{4}, \frac{7}{29}, \frac{8}{33}, \frac{31}{128}, \frac{132}{545}, \frac{163}{673}, \text{ \&c.}$$

The first of these, $\frac{1}{4}$, gives the Julian intercalation of one day in four years, and is considerably too great. It supposes the year to contain 365 days 6 hours.

The second, $\frac{7}{29}$, gives seven intercalary days in twenty-nine years, and errs in defect, as it supposes a year of 365 days 5 hours 47 min. 35 sec.

The third, $\frac{8}{33}$, gives eight intercalations in thirty-three years, or seven successive intercalations at the end of four years respectively, and the eighth at the end of five years. This supposes the year to contain 365 days 5 hours 49 min. 5·45 sec.

The fourth fraction, $\frac{31}{128} = \frac{24+7}{99+29} = \frac{3 \times 8 + 7}{3 \times 33 + 29}$, combines three periods of thirty-three years with one of twenty-nine, and would consequently be very convenient in application. It supposes the year to consist of 365 days 5 hours 48 min. 45 sec., and is practically exact.

The fraction $\frac{8}{33}$ offers a convenient and very accurate method of intercalation. It implies a year differing in excess from the true year only by 19·45 seconds, while the Gregorian year is too long by 26 seconds. It produces a much nearer coincidence between the civil and solar years than the Gregorian method; and, by reason of its shortness of period, confines the evagations of the mean equinox from the true within much narrower limits. It has been stated by Scaliger, Weidler, Montucla, and others, that the modern Persians actually follow this method, and intercalate eight days in thirty-three years. The statement has, however, been contested on good authority; and it seems proved (see Delambre, *Astronomie Moderne*, tom. i. p.81) that the Persian intercalation combines the two periods $\frac{7}{29}$ and $\frac{8}{33}$. If they follow the combination $\frac{7+3\times8}{29+3\times33} = \frac{31}{128}$, their determination of the length of the tropical year has been extremely exact. The discovery of the period of thirty-three years is ascribed to Omar Cheyam, one of the eight astronomers appointed by Gelal-Eddin Malech Shah, sultan of Khorassan, to reform or construct a calendar, about the year 1079 of our era.

If the commencement of the year, instead of being retained at the same place in the seasons by a uniform method of intercalation, were made to depend on astronomical phenomena, the intercalations would succeed each other in an irregular manner, sometimes after four years and sometimes after five; and it would occasionally, though rarely indeed, happen, that it would be impossible to determine the day on which the year ought to begin. In the calendar, for example, which was attempted to be introduced in France in 1793, the beginning of the year was fixed at the midnight preceding the day in which the true autumnal equinox falls. But supposing the instant of the sun's entering into the sign *Libra* to be very near midnight, the small errors of the solar tables might render it doubtful to which day the equinox really belonged; and it would be in vain to have recourse to observation to obviate the difficulty. It is therefore infinitely more commodious to determine the commence-

ment of the year by a fixed rule of intercalation; and of the various methods which might be employed, no one, perhaps is on the whole more easy of application, or better adapted for the purpose of computation, than the Gregorian now in use. But a system of 31 intercalations in 128 years would be by far the most perfect as regards mathematical accuracy. Its adoption upon our present Gregorian calendar would only require the suppression of the usual bissextile once in every 128 years, and there would be no necessity for any further correction, as the error is so insignificant that it would not amount to a day in 100,000 years.

Of the Lunar Year and Luni-solar Periods. The lunar year, consisting of twelve lunar months, contains only 354 days; its commencement consequently anticipates that of the solar year by eleven days, and passes through the whole circle of the seasons in about thirty-four lunar years. It is therefore so obviously ill-adapted to the computation of time, that, excepting the modern Jews and Mahometans, almost all nations who have regulated their months by the moon have employed some method of intercalation by means of which the beginning of the year is retained at nearly the same fixed place in the seasons.

In the early ages of Greece the year was regulated entirely by the moon. Solon divided the year into twelve months, consisting alternately of twenty-nine and thirty days, the former of which were called *deficient* months, and the latter *full* months. The lunar year, therefore, contained 354 days, falling short of the exact time of twelve lunations by about 8·8 hours. The first expedient adopted to reconcile the lunar and solar years seems to have been the addition of a month of thirty days to every second year. Two lunar years would thus contain 25 months, or 738 days, while two solar years, of $365\frac{1}{4}$ days each, contain $730\frac{1}{2}$ days. The difference of $7\frac{1}{2}$ days was still too great to escape observation; it was accordingly proposed by Cleostratus of Tenedos, who flourished shortly after the time of Thales, to omit the biennary intercalation every eighth year. In fact, the $7\frac{1}{2}$ days by which two lunar years exceeded two solar years, amounted to thirty days, or a full month, in eight years. By inserting, therefore, three additional months instead of four in every period of eight years, the coincidence between the solar and lunar year would have been exactly restored if the latter had contained only 354 days, inasmuch as the period contains $354 \times 8 + 3 \times 30 = 2922$ days, corresponding with eight solar years of $365\frac{1}{4}$ days each. But the true time of 99 lunations is 2923·528 days, which exceeds the above period by 1·528 days, or thirty-six hours and a few minutes. At the end of two periods, or sixteen years, the excess is three days, and at the end of 160 years, thirty days. It was therefore proposed to employ a period of 160 years, in which one of the intercalary months should be omitted; but as this period was too long to be of any practical use, it was never generally adopted. The common practice was to make occasional corrections as they became necessary, in order to preserve the relation between the octennial period and the state of the heavens; but these corrections being left to the care of incompetent persons, the calendar soon fell into great disorder, and no certain rule was followed till a new division of the year was proposed by Meton and Euctemon, which was immediately adopted in all the states and dependencies of Greece.

The mean motion of the moon in longitude, from the mean equinox, during a Julian year of 365·25 days (according to Hansen's *Tables de la Lune*, London, 1857, pages 15, 16) is, at the present date, $13 \times 360° + 477644''·409$; that of the sun being $360° + 27''·685$. Thus the corresponding relative mean geocentric motion of the moon from the sun is $12 \times 360° + 477616''·724$; and the duration of the mean synodic revolution of the moon, or lunar month, is therefore $\frac{360°}{12 \times 360° + 477616''·724} \times 365·25 = 29·530588$ days, or 29 days, 12 hours, 44 min. 2·8 sec.

The *Metonic Cycle*, which may be regarded as the *chef-d'œuvre* of ancient astronomy, is a period of nineteen solar years, after which the new moons again happen on the same days of the year. In nineteen solar years there are 235 lunations, a number which, on being divided by nineteen, gives twelve lunations for each year, with seven of a remainder, to be distributed among the years of the period. The period of Meton, therefore, consisted of twelve years containing twelve months each, and seven years containing thirteen months each; and these last formed the third, fifth, eighth, eleventh, thirteenth, sixteenth, and nineteenth years of the cycle. As it had now been discovered that the exact length of the lunation is a little more than twenty-nine and a half days, it became necessary to abandon the alternate succession of full and deficient months; and, in order to preserve a more accurate correspondence between the civil month and the lunation, Meton divided the cycle into 125 full months of thirty days, and 110 deficient months of twenty-nine days each. The number of days in the period was therefore 6940. In order to distribute the deficient months through the period in the most equable manner, the whole period may be regarded as consisting of 235 full months of thirty days, or of 7050 days, from which 110 days are to be deducted. This gives one day to be suppressed in sixty-four; so that if we suppose the months to contain each thirty days, and then omit every sixty-fourth day in reckoning from the beginning of the period, those months in which the omission takes place will, of course, be the deficient months.

The number of days in the period being known, it is easy to ascertain its accuracy both in respect of the solar and lunar motions. The exact length of nineteen solar years is $19 \times 365·2422 = 6939·6018$ days, or 6939 days 14 hours 26·592 minutes; hence the period, which is exactly 6940 days, exceeds nineteen revolutions of the sun by nine and a half hours nearly. On the other hand, the exact time of a synodic revolution of the moon is 29·530588 days; 235 lunations, therefore, contain $235 \times 29·530588 = 6939·68818$ days, or 6939 days 16 hours 31 minutes, so that the period exceeds 235 lunations by only seven and a half hours.

After the Metonic cycle had been in use about a century, a correction was proposed by Calippus. At the end of four cycles, or seventy-six years, the accumulation of the seven and a half hours of difference between the cycle and 235 lunations amounts to thirty hours, or one whole day and six hours. Calippus, therefore, proposed to quadruple the period of Meton, and deduct one day at the end of that time by changing one of the full months into a deficient month. The period of Calippus, therefore, consisted of three Metonic cycles of 6940 days each, and a period of 6939 days; and its error in respect of the moon, consequently, amounted only to six hours, or to one day in 304 years. This period exceeds seventy-six true solar years by fourteen hours and a quarter nearly, but coincides exactly with seventy-six Julian years; and in the time of Calippus the length of the solar year was almost universally supposed to be exactly $365\frac{1}{4}$ days. The Calippic period is frequently referred to as a date by Ptolemy.

ECCLESIASTICAL CALENDAR.—The ecclesiastical calendar, which is adopted in all the Catholic, and most of the Protestant countries of Europe, is luni-solar, being regulated partly by the solar, and partly by the lunar year,—a circumstance which gives rise to the distinction between the movable and immovable feasts. So early as the 2d century of our era, great disputes had arisen among the Christians respecting the proper time of celebrating Easter, which governs all the other movable feasts. The Jews celebrated their passover on the 14th day of the *first month*, that is to say, the lunar month of which the fourteenth day either falls on, or next follows, the day of the vernal equinox.

Most Christian sects agreed that Easter should be celebrated on a Sunday. Others followed the example of the Jews, and adhered to the 14th of the moon; but these, as usually happened to the minority, were accounted heretics, and received the appellation of Quartodecimans. In order to terminate dissensions, which produced both scandal and schism in the church, the Council of Nice, which was held in the year 325, ordained that the celebration of Easter should thenceforth always take place on the Sunday which immediately follows the full moon that happens upon, or next after, the day of the vernal equinox. Should the 14th of the moon, which is regarded as the day of full moon, happen on a Sunday, the celebration of Easter was deferred to the Sunday following, in order to avoid concurrence with the Jews and the above-mentioned heretics. The observance of this rule renders it necessary to reconcile three periods which have no common measure, namely, the week, the lunar month, and the solar year; and as this can only be done approximately, and within certain limits, the determination of Easter is an affair of considerable nicety and complication. It is to be regretted that the reverend fathers who formed the Council of Nice were not advised to abandon the moon altogether, and appoint Easter to be celebrated on the first or second Sunday of April. The ecclesiastical calendar would in that case have possessed all the simplicity and uniformity of the civil calendar, which only requires the adjustment of the civil to the solar year; but they were probably not sufficiently versed in astronomy to be aware of the practical difficulties which their regulation had to encounter.

Dominical Letter.—The first problem which the construction of the calendar presents is to connect the week with the year, or to find the day of the week corresponding to a given day of any year of the era. As the number of days in the week and the number in the year are prime to one another, two successive years cannot begin with the same day; for if a common year begins, for example, with Sunday, the following year will begin with Monday, and if a leap year begins with Sunday, the year following will begin with Tuesday. For the sake of greater generality, the days of the week are denoted by the first seven letters of the alphabet, A, B, C, D, E, F, G, which are placed in the calendar beside the days of the year, so that A stands opposite the first day of January, B opposite the second, and so on to G, which stands opposite the seventh; after which A returns to the eighth, and so on through the 365 days of the year. Now, if one of the days of the week, Sunday for example, is represented by E, Monday will be represented by F, Tuesday by G, Wednesday by A, and so on; and every Sunday through the year will have the same character E, every Monday F, and so with regard to the rest. The letter which denotes Sunday is called the *Dominical Letter*, or the *Sunday Letter;* and when the dominical letter of the year is known, the letters which respectively correspond to the other days of the week become known at the same time.

Solar Cycle.—In the Julian calendar the dominical letters are readily found by means of a short cycle, in which they recur in the same order without interruption. The number of years in the intercalary period being four, and the days of the week being seven, their product is $4 \times 7 = 28$; twenty-eight years is therefore a period which includes all the possible combinations of the days of the week with the commencement of the year. This period is called the *Solar Cycle*, or the *Cycle of the Sun*, and restores the first day of the year to the same day of the week. At the end of the cycle the dominical letters return again in the same order on the same days of the month; hence a table of dominical letters, constructed for twenty-eight years will serve to show the dominical letter of any given year from the commencement of the era to the reformation. The cycle, though probably not invented before the time of the Council of Nice, is regarded as having commenced nine years before the era, so that the year *one* was the tenth of the solar cycle. To find the year of the cycle, we have therefore the following rule:—*Add nine to the date, divide the sum by twenty-eight; the quotient is the number of cycles elapsed, and the remainder is the year of the cycle.* Should there be no remainder, the proposed year is the twenty-eighth or last of the cycle. This rule is conveniently expressed by the formula $\left(\frac{x+9}{28}\right)_r$, in which x denotes the date, and the symbol r denotes that the remainder, which arises from the division of $x+9$ by 28, is the number required. Thus, for 1840, we have $\frac{1840+9}{28} = 66\frac{1}{28}$; therefore $\left(\frac{1840+9}{28}\right)_r = 1$, and the year 1840 is the first of the solar cycle. In order to make use of the solar cycle in finding the dominical letter, it is necessary to know that the first year of the Christian era began with Saturday. The dominical letter of that year, which was the tenth of the cycle, was consequently B. The following year, or the 11th of the cycle, the letter was A; then G. The fourth year was bissextile, and the dominical letters were F, E; the following year D, and so on. In this manner it is easy to find the dominical letter belonging to each of the twenty-eight years of the cycle. But at the end of a century the order is interrupted in the Gregorian calendar by the secular suppression of the leap year; hence the cycle can only be employed during a century. In the reformed calendar the intercalary period is four hundred years, which number being multiplied by seven, gives two thousand eight hundred years as the interval in which the coincidence is restored between the days of the year and the days of the week. This long period, however, may be reduced to four hundred years; for since the dominical letter goes back five places every four years, its variation in four hundred years, in the Julian calendar, was five hundred places, which is equivalent to only three places (for five hundred divided by seven leaves three); but the Gregorian calendar suppresses exactly three intercalations in four hundred years, so that after four hundred years the dominical letters must again return in the same order.

Hence the following table of dominical letters for four hundred years will serve to show the dominical letter of any year in the Gregorian calendar for ever. It contains four columns of letters, each column serving for a century. In order to find the column from which the letter in any given case is to be taken, strike off the two last figures of the date, divide the preceding figures by four, and the remainder will indicate the column. The symbol X, employed in the formula at the top of the column, denotes the number of centuries, that is, the figures remaining after the last two have been struck off. For example, required the dominical letter of the year 1839? In this case $X = 18$, therefore $\left(\frac{X}{4}\right)_r = 2$; and in the second column of letters, opposite 39, in the table we find F, which is the letter of the proposed year.

It deserves to be remarked, that as the dominical letter of the first year of the era was B, the first column of the following table will give the dominical letter of every year from the commencement of the era to the reformation. For this purpose divide the date by 28, and the letter opposite the remainder, in the first column of figures, is the dominical letter of the year. For example, supposing the date to be 1148. On dividing by 28, the remainder is 0, or 28; and opposite 28, in the first column of letters, we find D, C, the dominical letters of the year 1148.

TABLE I.—*Dominical Letters.*

Years of the Century.	$\left(\frac{X}{4}\right)_r=1$	$\left(\frac{X}{4}\right)_r=2$	$\left(\frac{X}{4}\right)_r=3$	$\left(\frac{X}{4}\right)_r=0$
0	C	E	G	B, A

Lunar Cycle and Golden Number.—In connecting the lunar month with the solar year, the framers of the ecclesiastical calendar adopted the period of Meton, or lunar cycle, which they supposed to be exact. A different arrangement has, however, been followed with respect to the distribution of the months. The lunations are supposed to consist of twenty-nine and thirty days alternately, or the lunar year of 354 days; and in order to make up nineteen solar years, six embolismic or intercalary months, of thirty days each, are introduced in the course of the cycle, and one of twenty-nine days is added at the end. This gives 19 × 354 + 6 × 30 + 29 = 6935 days, to be distributed among 235 lunar months. But every leap year one day must be added to the lunar month in which the 29th of February is included. Now if leap year happens on the first, second, or third year of the period, there will be five leap years in the period, but only four when the first leap year falls on the fourth. In the former case the number of days in the period becomes 6940 and in the latter 6939. The mean length of the cycle is therefore 6939¾ days, agreeing exactly with nineteen Julian years.

By means of the lunar cycle the new moons of the calendar were indicated before the reformation. As the cycle restores these phenomena to the same days of the civil month, they will fall on the same days in any two years which occupy the same place in the cycle; consequently a table of the moon's phases for 19 years will serve for any year whatever when we know its number in the cycle. This number is called the *Golden Number*, either because it was so termed by the Greeks, or because it was usual to mark it with red letters in the calendar. The Golden Numbers were introduced into the calendar about the year 530, but disposed as they would have been if they had been inserted at the time of the Council of Nice. The cycle is supposed to commence with the year in which the new moon falls on the 1st of January, which took place the year preceding the commencement of our era. Hence, to find the Golden Number N, for any year x, we have $N = \left(\frac{x+1}{19}\right)_r$, which gives the following rule: *Add* 1 *to the date, divide the sum by* 19; *the quotient is the number of cycles elapsed, and the remainder is the Golden Number.* When the remainder is 0, the proposed year is of course the last or 19th of the cycle. It ought to be remarked that the new moons, determined in this manner, may differ from the astronomical new moons sometimes as much as two days. The reason is, that the sum of the solar and lunar inequalities, which are compensated in the whole period, may amount in certain cases to 10°, and thereby cause the new moon to arrive on the second day before or after its mean time.

Dionysian Period.—The cycle of the sun brings back the days of the month to the same day of the week; the lunar cycle restores the new moons to the same day of the month; therefore 28 × 19 = 532 years, includes all the variations in respect of the new moons and the dominical letters, and is consequently a period after which the new moons again occur on the same day of the month and the same day of the week. This is called the *Dionysian* or *Great Paschal Period*, from its having been employed by Dionysius Exiguus, familiarly styled "Denys the Little," in determining Easter Sunday. It was, however, first proposed by Victorius of Aquitain, who had been appointed by Pope Hilary to revise and correct the church calendar. Hence it is also called the *Victorian Period.* It continued in use till the Gregorian reformation.

Cycle of Indiction.—Besides the solar and lunar cycles, there is a third of 15 years, called the cycle of indiction, frequently employed in the computations of chronologists. This period is not astronomical, like the two former, but has reference to certain judicial acts which took place at stated epochs under the Greek emperors. Its commencement is referred to the 1st of January of the year 313 of the common era. By extending it backwards, it will be found that the first of the era was the fourth of the cycle of indiction. The number of any year in this cycle will therefore be given by the formula $\left(\frac{x+3}{15}\right)_r$, that is to say, *add 3 to the date, divide the sum by 15, and the remainder is the year of the indiction.* When the remainder is 0, the proposed year is the fifteenth of the cycle.

Julian Period.—The Julian period, proposed by the celebrated Joseph Scaliger as an universal measure of chronology, is formed by taking the continued product of the three cycles of the sun, of the moon, and of the indiction, and is consequently 28 × 19 × 15 = 7980

years. In the course of this long period no two years can be expressed by the same numbers in all the three cycles. Hence, when the number of any proposed year in each of the cycles is known, its number in the Julian period can be determined by the resolution of a very simple problem of the indeterminate analysis. It is unnecessary, however, in the present case to exhibit the general solution of the problem, because when the number in the period corresponding to any one year in the common era has been ascertained, it is easy to establish the correspondence for all other years, without having again recourse to the direct solution of the problem. We shall therefore find the number of the Julian period corresponding to the first of our era.

We have already seen that the year 1 of the era had 10 for its number in the solar cycle, 2 in the lunar cycle, and 4 in the cycle of indiction; the question is therefore to find a number such, that when it is divided by the three numbers 28, 19, and 15 respectively, the three quotients shall be 10, 2, and 4.

Let x, y, and z be the three quotients of the divisions; the number sought will then be expressed by $28x + 10$, by $19y + 2$, or by $15z + 4$. Hence the two equations

$$28x + 10 = 19y + 2 = 15z + 4.$$

To resolve the equation $28x + 10 = 19y + 2$, or $y = x + \frac{9x + 8}{19}$, let $m = \frac{9x + 8}{19}$, we have then $x = 2m + \frac{m - 8}{9}$.

Let $\frac{m - 8}{9} = m'$; then $m = 9m' + 8$; hence

$$x = 18m' + 16 + m' = 19m' + 16 \text{.........} (1).$$

Again, since $28x + 10 = 15z + 4$, we have

$$15z = 28x + 6, \text{ or } z = 2x - \frac{2x - 6}{15}.$$

Let $\frac{2x - 6}{15} = n$; then $2x = 15n + 6$, and $x = 7n + 3 + \frac{n}{2}$.

Let $\frac{n}{2} = n'$; then $n' = 2n'$; consequently

$$x = 14n' + 3 + n' = 15n' + 3 \text{...............} (2).$$

Equating the above two values of x, we have

$$15n' + 3 = 19m' + 16; \text{ whence } n' = m' + \frac{4m' + 13}{15}.$$

Let $\frac{4m' + 13}{15} = p$; we have then

$$4m' = 15p - 13, \text{ and } m' = 4p - \frac{p + 13}{4}.$$

Let $\frac{p + 13}{4} = p'$; then $p = 4p' - 13$;

$$\text{whence } m' = 16p' - 52 - p' = 15p' - 52.$$

Now in this equation p' may be any number whatever, provided $15p'$ exceed 52. The smallest value of p' (which is the one here wanted) is therefore 4; for $15 \times 4 = 60$. Assuming therefore $p' = 4$, we have $m' = 60 - 52 = 8$; and consequently, since $x = 19m' + 16$, $x = 19 \times 8 + 16 = 168$. The number required is consequently $28 \times 168 + 10 = 4714$.

Having found the number 4714 for the first of the era, the correspondence of the years of the era and of the period is as follows:—

Era,	1,	2,	3,...	x,
Period,	4714,	4715,	4716,...	$4713 + x$;

from which it is evident, that if we take P to represent the year of the Julian period, and x the corresponding year of the Christian era, we shall have

$$P = 4713 + x, \text{ and } x = P - 4713.$$

With regard to the numeration of the years previous to the commencement of the era, the practice is not uniform. Chronologists, in general, reckon the year preceding the first of the era -1, the next preceding -2, and so on. In this case

Era,	-1,	-2,	-3,...	$-x$,
Period,	4713,	4712,	4711,..	$4714 - x$;

whence

$$P = 4714 - x, \text{ and } x = 4714 - P.$$

But astronomers, in order to preserve the uniformity of computation, make the series of years proceed without interruption, and reckon the year preceding the first of the era 0. Thus

Era,	0,	-1,	-2,...	$-x$,
Period,	4713,	4712,	4711,...	$4713 - x$.

therefore, in this case

$$P = 4713 - x, \text{ and } x = 4713 - P.$$

Reformation of the Calendar.—The ancient church calendar was founded on two suppositions, both erroneous, namely, that the year contains $365\frac{1}{4}$ days, and that 235 lunations are exactly equal to nineteen solar years. It could not therefore long continue to preserve its correspondence with the seasons, or to indicate the days of the new moons with the same accuracy. About the year 730 the venerable Bede had already perceived the anticipation of the equinoxes, and remarked that these phenomena then took place about three days earlier than at the time of the Council of Nice. Five centuries after the time of Bede, the divergence of the true equinox from the 21st of March, which now amounted to seven or eight days, was pointed out by John of Sacrobosco, in a work published under the title *De Anni Ratione;* and by Roger Bacon, in a treatise *De Reformatione Calendarii*, which, though never published, was transmitted to the Pope. These works were probably little regarded at the time; but as the errors of the calendar went on increasing, and the true length of the year, in consequence of the progress of astronomy, became better known, the project of a reformation was again revived in the 15th century; and in 1474 Pope Sextus IV. invited Regiomontanus, the most celebrated astronomer of the age, to Rome, to superintend the reconstruction of the calendar. The premature death of Regiomontanus caused the design to be suspended for the time; but in the following century numerous memoirs appeared on the subject, among the authors of which were Stöffler, Albert Pighius, John Schöner, Lucas Gauricus, and other mathematicians of celebrity. At length Pope Gregory XIII. perceiving that the measure was likely to confer a great eclat on his pontificate, undertook the long-desired reformation; and having found the Governments of the principal Catholic states ready to adopt his views, he issued a brief in the month of March 1582, in which he abolished the use of the ancient calendar, and substituted that which has since been received in almost all Christian countries under the name of the *Gregorian Calendar* or *New Style*. The author of the system adopted by Gregory was Aloysius Lilius, or Luigi Lilio Ghiraldi, a learned astronomer and physician of Naples, who died, however, before its introduction; but the individual who most contributed to give the ecclesiastical calendar its present form, and who was charged with all the calculations necessary for its verification, was Clavius, by whom it was completely developed and explained in a great folio treatise of 800 pages, published in 1603, the title of which is given at the end of this article.

It has already been mentioned that the error of the Julian year was corrected in the Gregorian calendar by the suppression of three intercalations in 400 years. In order to restore the commencement of the year to the same place in the seasons that it had occupied at the time of the Council of Nice, Gregory directed the day following the feast of St Francis, that is to say the 5th of October, to be reckoned the 15th of that month. By this regulation the vernal equinox which then happened on the 11th of March was restored to the 21st. From 1582 to 1700 the difference between the old and new style continued to be ten days; but 1700 being a leap year in the Julian calendar, and a common year in the Gregorian, the difference of the styles during the 18th century was eleven days. The year 1800 was also common in the new calendar, and, consequently, the difference in the present century is twelve days. From 1900 to 2100 inclusive it will be thirteen days.

The restoration of the equinox to its former place in the year, and the correction of the intercalary period, were attended with no difficulty; but Lilius had also to adapt the lunar year to the new rule of intercalation. The lunar

cycle contained 6939 days 18 hours, whereas the exact time of 235 lunations, as we have already seen, is 235 × 29·530588 = 6939 days 16 hours 31 minutes. The difference, which is 1 hour 29 minutes, amounts to a day in 308 years, so that at the end of this time the new moons occur one day earlier than they are indicated by the golden numbers. During the 1257 years that elapsed between the Council of Nice and the reformation, the error had accumulated to four days, so that the new moons which were marked in the calendar as happening, for example, on the 5th of the month, actually fell on the 1st. It would have been easy to correct this error by placing the golden numbers four lines higher in the new calendar; and the suppression of the ten days had already rendered it necessary to place them ten lines lower, and to carry those which belonged, for example, to the 5th and 6th of the month, to the 15th and 16th. But, supposing this correction to have been made, it would have again become necessary, at the end of 308 years, to advance them one line higher, in consequence of the accumulation of the error of the cycle to a whole day. On the other hand, as the golden numbers were only adapted to the Julian calendar, every omission of the centenary intercalation would require them to be placed one line lower, opposite the 6th, for example, instead of the 5th of the month; so that, generally speaking, the places of the golden numbers would have to be changed every century. On this account Lilius thought fit to reject the golden numbers from the calendar, and supply their place by another set of numbers called *Epacts*, the use of which we shall now proceed to explain.

Epacts.—Epact is a word of Greek origin, employed in the calendar to signify the moon's age at the beginning of the year. The common solar year containing 365 days, and the lunar year only 354 days, the difference is eleven; whence, if a new moon fall on the 1st of January in any year, the moon will be eleven days old on the first day of the following year, and twenty-two days on the first of the third year. The numbers eleven and twenty-two are therefore the epacts of those years respectively. Another addition of eleven gives thirty-three for the epact of the fourth year; but in consequence of the insertion of the intercalary month in each third year of the lunar cycle, this epact is reduced to three. In like manner the epacts of all the following years of the cycle are obtained by successively adding eleven to the epact of the former year, and rejecting thirty as often as the sum exceeds that number. They are therefore connected with the golden numbers by the formula $\left(\frac{11\,n}{30}\right)_r$, in which n is any whole number; and for a whole lunar cycle (supposing the first epact to be 11), they are as follows: 11, 22, 3, 14, 25, 6, 17, 28, 9, 20, 1, 12, 23, 4, 15, 26, 7, 18, 29. But the order is interrupted at the end of the cycle; for the epact of the following year, found in the same manner, would be 29 + 11 = 40 or 10, whereas it ought again to be 11 to correspond with the moon's age and the golden number 1. The reason of this is, that the intercalary month, inserted at the end of the cycle, contains only twenty-nine days instead of thirty; whence, after 11 has been added to the epact of the year corresponding to the golden number 19, we must reject twenty-nine instead of thirty, in order to have the epact of the succeeding year; or, which comes to the same thing, we must add twelve to the epact of the last year of the cycle, and then reject thirty as before.

This method of forming the epacts might have been continued indefinitely if the Julian intercalation had been followed without correction, and the cycle been perfectly exact; but as neither of these suppositions is true, two equations or corrections must be applied, one depending on the error of the Julian year, which is called the solar equation; the other on the error of the lunar cycle, which is called the lunar equation. The solar equation occurs three times in 400 years, namely, in every secular year which is not a leap year; for in this case the omission of the intercalary day causes the new moons to arrive one day later in all the following months, so that the moon's age at the end of the month is one day less than it would have been if the intercalation had been made, and the epacts must accordingly be all diminished by unity. Thus the epacts 11, 22, 3, 14, &c., become 10, 21, 2, 13, &c. On the other hand, when the time by which the new moons anticipate the lunar cycle amounts to a whole day, which, as we have seen, it does in 308 years, the new moons will arrive one day earlier, and the epacts must consequently be increased by unity. Thus the epacts 11, 22, 3, 14, &c., in consequence of the lunar equation, become 12, 23, 4, 15, &c. In order to preserve the uniformity of the calendar, the epacts are changed only at the commencement of a century; the correction of the error of the lunar cycle is therefore made at the end of 300 years. In the Gregorian calendar this error is assumed to amount to one day in 312½ years, or eight days in 2500 years, an assumption which requires the line of epacts to be changed seven times successively at the end of each period of 300 years, and once at the end of 400 years; and, from the manner in which the epacts were disposed at the reformation, it was found most correct to suppose one of the periods of 2500 years to terminate with the year 1800.

The years in which the solar equation occurs, counting from the reformation, are 1700, 1800, 1900, 2100, 2200, 2300, 2500, &c. Those in which the lunar equation occurs are 1800, 2100, 2400, 2700, 3000, 3300, 3600, 3900, after which, 4300, 4600, and so on. When the solar equation occurs, the epacts are diminished by unity; when the lunar equation occurs, the epacts are augmented by unity; and when both equations occur together, as in 1800, 2100, 2700, &c., they compensate each other, and the epacts are not changed.

In consequence of the solar and lunar equations, it is evident that the epact, or moon's age at the beginning of the year, must, in the course of centuries, have all different values from one to thirty inclusive, corresponding to the days in a full lunar month. Hence, for the construction of a perpetual calendar, there must be thirty different sets or lines of epacts. These are exhibited in the subjoined table (Table III.) called the *Extended Table of Epacts*, which is constructed in the following manner. The series of golden numbers is written in a line at the top of the table, and under each golden number is a column of thirty epacts, arranged in the order of the natural numbers, beginning at the bottom and proceeding to the top of the column. The first column, under the golden number 1, contains the epacts, 1, 2, 3, 4, &c., to 30 or 0. The second column, corresponding to the following year in the lunar cycle, must have all its epacts augmented by 11; the lowest number, therefore, in the column is 12, then 13, 14, 15, and so on. The third column, corresponding to the golden number 3, has for its first epact 12 + 11 = 23; and in the same manner all the nineteen columns of the table are formed. Each of the thirty lines of epacts is designated by a letter of the alphabet, which serves as its index or argument. The order of the letters, like that of the numbers, is from the bottom of the column upwards.

In the tables of the church calendar the epacts are usually printed in Roman numerals, excepting the last, which is designated by an asterisk (*), used as an indefinite symbol to denote 30 or 0, and 25, which in the last eight columns is expressed in Arabic characters, for a reason that will immediately be explained. In the table

here given, this distinction is made by means of an accent placed over the last figure.

At the reformation the epacts were given by the line D. The year 1600 was a leap year; the intercalation accordingly took place as usual, and there was no interruption in the order of the epacts; the line D was employed till 1700. In that year the omission of the intercalary day rendered it necessary to diminish the epacts by unity, or to pass to the line C. In 1800 the solar equation again occurred, in consequence of which it was necessary to descend one line to have the epacts diminished by unity; but in this year the lunar equation also occurred, the anticipation of the new moons having amounted to a day; the new moons accordingly happened a day earlier, which rendered it necessary to take the epacts in the next higher line. There was, consequently, no alteration; the two equations destroyed each other. The line of epacts belonging to the present century is therefore C. In 1900 the solar equation occurs, after which the line is B. The year 2000 is a leap year, and there is no alteration. In 2100 the equations again occur together and destroy each other, so that the line B will serve three centuries, from 1900 to 2200. From that year to 2300 the line will be A. In this manner the line of epacts belonging to any given century is easily found, and the method of proceeding is obvious. When the solar equation occurs alone, the line of epacts is changed to the next lower in the table; when the lunar equation occurs alone, the line is changed to the next higher; when both equations occur together, no change takes place. In order that it may be perceived at once to what centuries the different lines of epacts respectively belong, they have been placed in a column on the left hand side of the following table.

TABLE III.—*Extended Table of Epacts.*

Years.	Index.	Golden Numbers.																		
		1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19

The use of the epacts is to show the days of the new moons, and consequently the moon's age on any day of the year. For this purpose they are placed in the calendar (Table IV.) along with the days of the month and dominical letters, in a retrograde order, so that the asterisk stands beside the 1st of January, 29 beside the 2nd, 28 beside the 3rd, and so on to 1, which corresponds to the 30th. After this comes the asterisk, which corresponds to the 31st of January, then 29, which belongs to the 1st of February, and so on to the end of the year. The reason of this distribution is evident. If the last lunation of any year ends, for example, on the 2nd of December, the new moon falls on the 3rd; and the moon's age on the 31st, or at the end of the year, is twenty-nine days. The epact of the following year is therefore twenty-nine. Now that lunation having commenced on the 3rd of December, and consisting of thirty days, will end on the 1st of January. The 2nd of January is therefore the day of the new moon, which is indicated by the epact twenty-nine. In like manner, if the new moon fell on the 4th of December, the epact of the following year would be twenty-eight, which, to indicate the day of next new moon, must correspond to the 3rd of January.

When the epact of the year is known, the days on which the new moons occur throughout the whole year are shown by Table IV., which is called the *Gregorian Calendar of Epacts.* For example, the golden number of the year 1832, is $\left(\frac{1832+1}{19}\right)_r = 9$, and the epact, as found in Table III., is twenty-eight. This epact occurs at the 3rd of January, the 2nd of February, the 3rd of March, the 2nd of April, the 1st of May, &c.; and these days are consequently the days of the ecclesiastical new moons in 1832. The astronomical new moons generally take place one or two days, sometimes even three days, earlier than those of the calendar.

There are some artifices employed in the construction of this table, to which it is necessary to pay attention. The thirty epacts correspond to the thirty days of a full lunar month; but the lunar months consist of twenty-nine and thirty days alternately, therefore in six months of the year the thirty epacts must correspond only to twenty-nine days. For this reason the epacts twenty-five and twenty-four are placed together, so as to belong only to one day in the months of February, April, June, August, September, and November, and in the same months another 25′, distinguished by an accent, or by being printed in a different character, is placed beside 26, and belongs to the same day. The reason for doubling the 25 was to prevent the new moons from being indicated in the calendar as happening twice on the same day in the course of the lunar cycle, a thing which actually cannot take place. For example, if we observe the line B in Table III., we shall see that it contains both the epacts twenty-four and twenty-five, so that if these correspond to the same day of the month, two new moons would be indicated as happening on that day within nineteen years. Now the three epacts 24, 25, 26, can never occur in the same line; therefore in those lines in which 24 and 25 occur, the 25 is accented, and placed in the calendar beside 26. When 25 and 26 occur in the same line of epacts, the 25 is not accented, and in the calendar stands beside 24. The lines of epacts in which 24 and 25 both occur, are those which are marked by one of the eight letters *b*, *e*, *k*, *n*, *r*, B, E, N, in all of which 25′ stands in a column corresponding to a golden number higher than 11. There are also eight lines in which 25 and 26 occur, namely, *c*, *f*, *l*, *p*, *s*, C, F, P. In the other 14 lines, 25 either does not occur at all, or it occurs in a line in which neither 24 nor 26 is found. From this it appears, that if the golden number of the year exceeds 11, the epact 25, in six months of the year, must correspond to the same day in the calendar as 26; but if the golden number does not exceed 11, that epact must correspond to the same day as 24. Hence the reason for distinguishing 25 and 25′. In using the calendar, if the epact of the year is 25, and the golden number not above 11, take 25; but if the golden number exceeds 11, take 25′.

Another peculiarity requires explanation. The epact 19′ (also distinguished by an accent or different character) is placed in the same line with 20 at the 31st of December. It is, however, only used in those years in which the epact 19 concurs with the golden number 19. When the golden number is 19, that is to say, in the last year of the lunar cycle, the supplementary month contains only 29 days. Hence, if in that year the epact should be 19, a new moon would fall on the 2nd of December, and the lunation would terminate on the 30th, so that the next new moon would arrive on the 31st. The epact of the year, therefore, or 19, must stand beside that day, whereas, according to the regular order, the epact corresponding to the 31st of December is 20; and this is the reason for the distinction.

As an example of the use of the preceding tables, suppose it were required to determine the moon's age on the 10th of April 1832. In 1832 the golden number is $\left(\frac{1832+1}{19}\right)_r = 9$, and the line of epacts belonging to the century is C. In Table III. under 9, and in the line C, we find the epact 28. In the calendar, Table IV. look for April, and the epact 28 is found opposite the second day. The 2nd of April is therefore the first day of the moon, and the 10th is consequently the ninth day of the moon.

Again, suppose it were required to find the moon's age on the 2nd of December in the year 1916. In this case the golden number is $\left(\frac{1916+1}{19}\right)_r = 17$, and in Table III., opposite to 1900, the line of epacts is B. Under 17, in line B, the epact is 25′. In the calendar this epact first occurs before the 2nd of December at the 26th of November. The 26th of November is consequently the first day of the moon, and the 2nd of December is therefore the seventh day.

Easter.—The next, and indeed the principal use of the calendar, is to find Easter, which, according to the regulation of the Council of Nice, must be determined from the following conditions:—*1st*, Easter must be celebrated on a Sunday; *2nd*, this Sunday must *follow* the 14th day of the paschal moon, so that if the 14th of the paschal moon falls on a Sunday, then Easter must be celebrated on the Sunday following; *3rd*, the paschal moon is that of which the 14th day falls on or next follows the day of the vernal equinox; *4th*, the equinox is fixed invariably in the calendar on the 21st of March. Sometimes a misunderstanding has arisen from not observing that this regulation is to be construed according to the tabular full moon as determined from the epact, and not by the true full moon, which, in general, occurs one or two days earlier.

From these conditions it follows that the paschal full moon, or the 14th of the paschal moon, cannot happen before the 21st of March, and that Easter in consequence cannot happen before the 22nd of March. If the 14th of the moon falls on the 21st, the new moon must fall on the 8th; for $21 - 13 = 8$; and the paschal new moon cannot happen before the 8th; for suppose the new moon to fall on the 7th, then the full moon would arrive on the 20th, or the day before the equinox. The following moon would be the paschal moon. But the fourteenth of this moon falls at the latest on the 18th of April, or 29 days after the 20th of March; for by reason of the double epact that occurs at the 4th and 5th of April, this lunation has only 29 days. Now, if in this case the 18th of April is Sunday, then Easter must be celebrated on the following Sunday, or the 25th of April. Hence Easter Sunday cannot happen earlier than the 22nd of March, or later than the 25th of April.

Hence we derive the following rule for finding Easter Sunday from the tables:—*1st*, Find the golden number, and, from Table III., the epact of the proposed year. *2nd*, Find in the calendar (Table IV.) the first day after the 7th of March which corresponds to the epact of the year; this will be the first day of the paschal moon. *3rd*, Reckon thirteen days after that of the first of the moon, the following will be the 14th of the moon, or the day of the full paschal moon. *4th*, Find from Table I. the dominical letter of the year, and observe in the calendar the first day, after the fourteenth of the moon, which corresponds to the dominical letter; this will be Easter Sunday.

Example.—Required the day on which Easter Sunday falls in the year 1840? *1st*, For this year the golden number is $\left(\frac{1840+1}{19}\right)_r = 17$, and the epact (Table III. line C) is 26. *2nd*, After the 7th of March the epact 26 first occurs in Table III. at the 4th of April, which, therefore, is the day of the new moon. *3rd*, Since the new moon falls on the 4th, the full moon is on the 17th ($4 + 13 = 17$). *4th*, The dominical letters of 1840 are E, D (Table I.), of which D must be taken, as E belongs only to January and February. After the 17th of April D first occurs in the calendar (Table IV.) at the 19th. Therefore, in 1840, Easter Sunday falls on the 19th of April. The operation is in all cases much facilitated by means of the following table:—

TABLE V.—*Perpetual Table, showing Easter.*

Such is the very complicated and artificial, though highly ingenious method, invented by Lilius, for the determination of Easter and the other movable feasts. Its principal, though perhaps least obvious advantage, consists in its being entirely independent of astronomical tables, or indeed of any celestial phenomena whatever; so that all chances of disagreement arising from the inevitable errors of tables, or the uncertainty of observation, are avoided, and Easter determined without the possibility of mistake. But this advantage is only procured by the sacrifice of some accuracy; for notwithstanding the cumbersome apparatus employed, the conditions of the problem are not always exactly satisfied, nor is it possible that they can be always satisfied by any similar method of proceeding. The equinox is fixed on the 21st of March, though the sun enters Aries generally on the 20th of that month, sometimes even on the 19th. It is accordingly quite possible that a full moon may arrive after the true equinox, and yet precede the 21st of March. This, therefore, would not be the paschal moon of the calendar, though it undoubtedly ought to be so, if the intention of the Council of Nice were rigidly followed. The new moons indicated by the epacts also differ from the astronomical new moons, and even from the mean new moons, in general by one or two days. In imitation of the Jews, who counted the time of the new moon, not from the moment of the actual phase, but from the time the moon first became visible after the conjunction, the fourteenth day of the moon is regarded as the full moon; but the moon is in opposition generally on the 16th day; therefore, when the new moons of the calendar nearly concur with the true new moons, the full moons are considerably in error. The epacts are also placed so as to indicate the full moons generally one or two days after the true full moons; but this was done purposely, to avoid the chance of concurring with the Jewish passover, which the framers of the calendar seem to have considered a greater evil than that of celebrating Easter a week too late.

We will now show in what manner this whole apparatus of methods and tables may be dispensed with, and the Gregorian calendar reduced to a few simple formulæ of easy computation.

And, first, to find the dominical letter. Let L denote the number of the dominical letter of any given year of the era. Then, since every year which is not a leap year ends with the same day as that with which it began, the dominical letter of the

following year must be $L-1$, retrograding one letter every common year. After x years, therefore, the number of the letter will be $L-x$. But as L can never exceed 7, the number x will always exceed L after the first seven years of the era. In order therefore to render the subtraction possible, L must be increased by some multiple of 7, as $7m$, and the formula then becomes $7m+L-x$. In the year preceding the first of the era, the dominical letter was C; for that year, therefore, we have $L=3$; consequently for any succeeding year x, $L=7m+3-x$, the years being all supposed to consist of 365 days. But every fourth year is a leap year, and the effect of the intercalation is to throw the dominical letter one place farther back. The above expression must therefore be diminished by the number of units in $\frac{x}{4}$, or by $\left(\frac{x}{4}\right)_w$ (this notation being used to denote the quotient, *in a whole number*, that arises from dividing x by 4). Hence in the Julian calendar the dominical letter is given by the equation $L=7m+3-x-\left(\frac{x}{4}\right)_w$.

This equation gives the dominical letter of any year from the commencement of the era to the reformation. In order to adapt it to the Gregorian calendar, we must first add the 10 days that were left out of the year 1582; in the second place we must add one day for every century that has elapsed since 1600, in consequence of the secular suppression of the intercalary day; and lastly we must deduct the units contained in a fourth of the same number, because every fourth centesimal year is still a leap year. Denoting therefore the number of the century (or the date after the two right-hand digits have been struck out) by c, the value of L must be increased by $10+(c-16)-\left(\frac{c-16}{4}\right)_w$. We have then

$$L=7m+3-x-\left(\frac{x}{4}\right)_w+10+(c-16)-\left(\frac{c-16}{4}\right)_w;$$

that is, since $3+10=13$ or 6 (the 7 days being rejected, as they do not affect the value of L),

$$L=7m+6-x-\left(\frac{x}{4}\right)_w+(c-16)-\left(\frac{c-16}{4}\right)_w;$$

This formula is perfectly general, and easily calculated.

As an example, let us take the year 1839. In this case,

$$x=1839, \left(\frac{x}{4}\right)_w=\left(\frac{1839}{4}\right)_w=459, c=18, c-16=2,$$

and $\left(\frac{c-16}{4}\right)_w=0$. Hence

$$L=7m+6-1839-459+2-0$$
$$L=7m-2290=7\times 328-2290.$$
$$L=6=\text{letter F.}$$

The year therefore begins with Tuesday. It will be remembered that in a leap year there are always two dominical letters, one of which is employed till the 29th of February, and the other till the end of the year. In this case, as the formula supposes the intercalation already made, the resulting letter is that which applies after the 29th of February. Before the intercalation the dominical letter had retrograded one place less. Thus for 1840 the formula gives D; during the first two months, therefore, the dominical letter is E.

In order to investigate a formula for the epact, let us make

E = the true epact of the given year;

J = the Julian epact, that is to say, the number the epact would have been if the Julian year had been still in use and the lunar cycle had been exact;

S = the correction depending on the solar year;

M = the correction depending on the lunar cycle;

then the equation of the epact will be

$$E=J+S+M;$$

so that E will be known when the numbers J, S, and M are determined.

The epact J depends on the golden number N, and must be determined from the fact that in 1582, the first year of the reformed calendar, N was 6, and J 26. For the following years, then, the golden numbers and epacts are as follows:

$$\begin{aligned}
&1583,\ N=7, && J=26+11-30=7;\\
&1584,\ N=8, && J=7+11 \quad =18;\\
&1585,\ N=9, && J=18+11 \quad =29;\\
&1586,\ N=10, && J=29+11-30=10;
\end{aligned}$$

and, therefore, in general $J=\left(\frac{26+11(N-6)}{30}\right)_r$. But the numerator of this fraction becomes by reduction $11N-40$ or $11N-10$ (the 30 being rejected, as the remainder only is sought) $=N+10(N-1)$; therefore, ultimately,

$$J=\left(\frac{N+10(N-1)}{30}\right)_r$$

On account of the solar equation S, the epact J must be diminished by unity every centesimal year, excepting always the fourth. After x centuries, therefore, it must be diminished by $x-\left(\frac{x}{4}\right)_w$. Now, as 1600 was a leap year, the first correction of the Julian intercalation took place in 1700; hence, taking c to denote the number of the century as before, the correction becomes $(c-16)-\left(\frac{c-16}{4}\right)_w$, which must be deducted from J. We have therefore

$$S=-(c-16)+\left(\frac{c-16}{4}\right)_w.$$

With regard to the lunar equation M, we have already stated that in the Gregorian calendar the epacts are increased by unity at the end of every period of 300 years seven times successively, and then the increase takes place once at the end of 400 years. This gives eight to be added in a period of twenty-five centuries, and $\frac{8x}{25}$ in x centuries. But $\frac{8x}{25}=\frac{1}{3}\left(x-\frac{x}{25}\right)$. Now, from the manner in which the intercalation is directed to be made (namely, seven times successively at the end of 300 years, and once at the end of 400), it is evident that the fraction $\frac{x}{25}$ must amount to unity when the number of centuries amounts to twenty-four. In like manner, when the number of centuries is $24+25=49$, we must have $\frac{x}{25}=2$; when the number of centuries is $24+2\times 25=74$, then $\frac{x}{25}=3$; and, generally, when the number of centuries is $24+n\times 25$, then $\frac{x}{25}=n+1$. Now this is a condition which will evidently be expressed in general by the formula $n-\left(\frac{n+1}{25}\right)_w$. Hence the correction of the epact, or the number of days to be intercalated after x centuries reckoned from the commencement of one of the periods of twenty-five centuries, is $\left\{\frac{x-\left(\frac{x+1}{25}\right)_w}{3}\right\}_w$. The last period of twenty-five centuries terminated with 1800; therefore, in any succeeding year, if c be the number of the century, we shall have $x=c-18$ and $x+1=c-17$. Let $\left(\frac{c-17}{25}\right)_w=a$, then for all years after 1800 the value of M will be given by the formula $\left(\frac{c-18-a}{3}\right)_w$; therefore, counting from the beginning of the calendar in 1582,

$$M=\left\{\frac{c-15-a}{3}\right\}_w.$$

By the substitution of these values of J, S, and M, the equation of the epact becomes

$$E=\left(\frac{N+10(N-1)}{30}\right)_r-(c-16)+\left(\frac{c-16}{4}\right)_w+\left(\frac{c-15-a}{3}\right)_w.$$

It may be remarked, that as $a=\left(\frac{c-17}{25}\right)_w$, the value of a will be 0 till $c-17=25$ or $c=42$; therefore, till the year 4200, a may be neglected in the computation. Had the anticipation of the new moons been taken, as it ought to have been, at one day in 308 years instead of 312½, the lunar equation would have occurred only twelve times in 3700 years, or eleven times successively at the end of 300 years, and then at the end of 400. In strict accuracy, therefore, a ought to have no value till $c-17=37$, or $c=54$, that is to say, till the year 5400. The above formula for the epact is given by Delambre (*Hist. de l'Astronomie Moderne*, tom. i. p. 9); it may be exhibited under a variety of forms, but the above is perhaps the best adapted for calculation. Another had previously been given by Gauss, but inaccurately, inasmuch as the correction depending on a was omitted.

Having determined the epact of the year, it only remains to find Easter Sunday from the conditions already laid down. Let

P = the number of days from the 21st of March to the 15th of the paschal moon, which is the first day on which Easter Sunday can fall;

p = the number of days from the 21st of March to Easter Sunday.

L = the number of the dominical letter of the year;

l = letter belonging to the day on which the 15th of the moon falls then, since Easter is the Sunday following the 14th of the moon, we have

$$p=P+(L-l),$$

which is commonly called the *number of direction*.

The value of L is always given by the formula for the dominical letter, and P and l are easily deduced from the epact, as will appear from the following considerations.

When $P = 1$, the full moon is on the 21st of March, and the new moon on the eighth $(21 - 13 = 8)$, therefore the moon's age on the 1st of March (which is the same as on the 1st of January) is twenty-three days; the epact of the year is consequently twenty-three. When $P = 2$ the new moon falls on the ninth, and the epact is consequently twenty-two; and, in general, when P becomes $1 + x$, E becomes $23 - x$, therefore $P + E = 1 + x + 23 - x = 24$, and $P = 24 - E$. In like manner, when $P = 1$, $l = D = 4$; for D is the dominical letter of the calendar belonging to the 22nd of March. But it is evident that when l is increased by unity, that is to say, when the full moon falls a day later, the epact of the year is diminished by unity; therefore, in general, when $l = 4 + x$, $E = 23 - x$, whence $l + E = 27$ and $l = 27 - E$. But P can never be less than 1 nor l less than 4, and in both cases $E = 23$. When, therefore, E is greater than 23, we must add 30 in order that P and l may have positive values in the formula $P = 24 - E$ and $l = 27 - E$. Hence there are two cases.

$$\text{When} < 24, \quad \begin{cases} P = 24 - E \\ l = 27 - E, \text{ or } \left(\dfrac{27 - E}{7}\right)_r, \end{cases}$$

$$\text{When } E > 23, \quad \begin{cases} P = 54 - E \\ l = 57 - E, \text{ or } \left(\dfrac{57 - E}{7}\right)_r \end{cases}$$

By substituting one or other of these values of P and l, according as the case may be, in the formula $p = P + (L - l)$, we shall have p, or the number of days from the 21st of March to Easter Sunday. It will be remarked, that as $L - l$ cannot either be 0 or negative, we must add 7 to L as often as may be necessary, in order that $L - l$ may be a positive whole number.

By means of the formulæ which we have now given for the dominical letter, the golden number, and the epact, Easter Sunday may be computed for any year after the reformation, without the assistance of any tables whatever. As an example, suppose it were required to compute Easter for the year 1840. By substituting this number in the formula for the dominical letter, we have $x = 1840$,

$c - 16 = 2$, $\left(\dfrac{c-16}{4}\right)_w = 0$, therefore

$$\begin{aligned} L &= 7m + 6 - 1840 - 460 + 2 \\ &= 7m - 2292 \\ &= 7 \times 328 - 2292 = 2296 - 2292 = 4 \\ L &= 4 = \text{letter D} \;\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots(1). \end{aligned}$$

For the golden number we have $N = \left(\dfrac{1840 + 1}{19}\right)_r$;

therefore $N = 17$ ……………………………………(2).

For the epact we have $\left(\dfrac{N + 10(N-1)}{30}\right)_r = \left(\dfrac{17 + 160}{30}\right)_r = \left(\dfrac{177}{30}\right)_r$

$= 27$; likewise $c - 16 = 18 - 16 = 2$, $\dfrac{c-15}{3} = 1$, $a = 0$; therefore

$$E = 27 - 2 + 1 = 26 \ldots\ldots\ldots\ldots\ldots\ldots\ldots(3).$$

Now since $E > 23$, we have for P and l,

$$P = 54 - E = 54 - 26 = 28,$$

$$l = \left(\frac{57 - E}{7}\right)_r = \left(\frac{57 - 26}{7}\right)_r = \left(\frac{31}{7}\right)_r = 3;$$

consequently, since $p = P + (L - l)$,

$$p = 28 + (4 - 3) = 29;$$

that is to say, Easter happens twenty-nine days after the 21st of March, or on the 19th April, the same result as was before found from the tables.

The principal church feasts depending on Easter, and the times of their celebration, are as follows:—

Septuagesima Sunday	is	9 weeks	before Easter.
First Sunday in Lent		6 weeks	
Ash Wednesday		46 days	
Rogation Sunday	is	5 weeks	after Easter.
Ascension day or Holy Thursday		39 days	
Pentecost or Whitsunday		7 weeks	
Trinity Sunday		8 weeks	

The Gregorian calendar was introduced into Spain, Portugal, and part of Italy, the same day as at Rome. In France it was received in the same year in the month of December, and by the Catholic states of Germany the year following. In the Protestant states of Germany the Julian calendar was adhered to till the year 1700, when it was decreed by the diet of Ratisbon that the new style and the Gregorian correction of the intercalation should be adopted. Instead, however, of employing the golden numbers and epacts for the determination of Easter and the movable feasts, it was resolved that the equinox and the paschal moon should be found by astronomical computation from the Rudolphine tables. But this method, though at first view it may appear more accurate, was soon found to be attended with numerous inconveniences, and was at length, in 1774, abandoned at the instance of Frederick II. king of Prussia. In Denmark and Sweden the reformed calendar was received about the same time as in the Protestant states of Germany. It is remarkable that Russia still adheres to the Julian reckoning.

In Great Britain the alteration of the style was for a long time successfully opposed by popular prejudice. The inconvenience, however, of using a different date from that employed by the greater part of Europe, in matters of history and chronology, began to be generally felt; and at length, in 1751, an Act of Parliament was passed for the adoption of the new style in all public and legal transactions. The difference of the two styles, which then amounted to eleven days, was removed by ordering the day following the 2d of September of the year 1752 to be accounted the 14th of that month; and in order to preserve uniformity in future, the Gregorian rule of intercalation respecting the secular years was adopted. At the same time, the commencement of the legal year was changed from the 25th of May to the 1st of January. In Scotland, the new style was adopted from the beginning of 1600, according to an Act of the privy council in December 1599. This fact is of importance with reference to the date of legal deeds executed in Scotland between that period and 1751, when the change was effected in England. With respect to the movable feasts, Easter is determined by the rule laid down by the Council of Nice; but instead of employing the new moons and epacts, the golden numbers are prefixed to the days of the *full* moons. In those years in which the line of epacts is changed in the Gregorian calendar, the golden numbers are removed to different days, and of course a new table is required whenever the solar or lunar equation occurs. The golden numbers have been placed so that Easter may fall on the same day as in the Gregorian calendar. The calendar of the church of England is therefore from century to century the same in form as the old Roman calendar, excepting that the golden numbers indicate the full moons instead of the new moons.

Hebrew Calendar.—In the construction of the Jewish calendar numerous details require attention. The calendar is dated from the Creation, which is considered to have taken place 3760 years and 3 months before the commencement of the Christian era. The year is luni-solar, and, according as it is ordinary or embolismic, consists of twelve or thirteen lunar months, each of which has 29 or 30 days. Thus the duration of the ordinary year is 354 days, and that of the embolismic is 384 days. In either case, it is sometimes made a day more, and sometimes a day less, in order that certain festivals may fall on proper days of the week for their due observance. The distribution of the embolismic years, in each cycle of 19 years, is determined according to the following rule:—

The number of the Hebrew year (Y) which has its commencement in a Gregorian year (x) is obtained by the addition of 3761 years; that is, $Y = x + 3761$. Divide the Hebrew year by 19; then the quotient is the number of the last completed cycle, and the remainder is the year of the current cycle. If the remainder be 3, 6, 8, 11, 14, 17, or 19 (0), the year is embolismic; if any other number, it is ordinary. Or, otherwise, if we find the remainder

$$R = \left(\frac{7Y + 1}{19}\right)_r$$

the year is embolismic when $R < 7$.

The calendar is constructed on the assumptions that the mean lunation is 29 days 12 hours 44 min. $3\frac{1}{3}$ sec., and that the year commences on, or immediately after, the new moon following the autumnal equinox. The mean solar year is also assumed to be 365 days 5 hours 55 min. $25\frac{25}{57}$ sec., so that a cycle of nineteen of such years, containing 6939 days 16 hours 33 min. $3\frac{1}{3}$ sec., is the exact measure of 235 of the assumed lunations. The year 5606 was the first of a cycle, and the mean new moon, appertaining to the 1st of Tisri for that year, was 1845, October 1, 15 hours 42 min. $43\frac{1}{3}$ sec., as computed by Lindo, and adopting the civil mode of reckoning from the previous midnight. The times of all future new moons may consequently be deduced by successively adding 29 days 12 hours 44 min. $3\frac{1}{3}$ sec. to this date.

To compute the times of the new moons which determine the commencement of successive years, it must be observed that in passing from an ordinary year the new moon of the following year is deduced by subtracting the interval that twelve lunations fall short of the corresponding Gregorian year of 365 or 366 days; and that, in passing from an embolismic year, it is to be found by adding the excess of thirteen lunations over the Gregorian year. Thus to deduce the new moon of Tisri, for the year immediately following any given year (Y), when Y is

$$\begin{cases} \text{ordinary, subtract } \binom{10}{11} \text{ days 15 hours 11 min. 20 sec.,} \\ \text{embolismic, add } \binom{18}{17} \text{ days 21 hours 32 min. } 43\tfrac{1}{3} \text{ sec.,} \end{cases}$$

the second-mentioned number of days being used, in each case, whenever the following or new Gregorian year is bissextile.

Hence, knowing which of the years are embolismic, from their ordinal position in the cycle, according to the rule before stated, the times of the commencement of successive years may be thus carried on indefinitely without any difficulty. But some slight adjustments will occasionally be needed for the reasons before assigned, viz., to avoid certain festivals falling on incompatible days of the week. Whenever the computed conjunction falls on a Sunday, Wednesday, or Friday, the new year is in such case to be fixed on the day after. It will also be requisite to attend to the following conditions:—

If the computed new moon be after 18 hours, the following day is to be taken, and if that happen to be Sunday, Wednesday, or Friday, it must be further postponed one day. If, for an ordinary year, the new moon falls on a Tuesday, as late as 9 hours 11 min. 20 sec., it is not to be observed thereon; and as it may not be held on a Wednesday, it is in such case to be postponed to Thursday. If, for a year immediately following an embolismic year, the computed new moon is on Monday, as late as 15 hours 30 min. 52 sec., the new year is to be fixed on Tuesday.

After the dates of commencement of the successive Hebrew years are finally adjusted, conformably with the foregoing directions, an estimation of the consecutive intervals, by taking the differences, will show the duration and character of the years that respectively intervene. According to the number of days thus found to be comprised in the different years, the days of the several months are distributed as in Table VI.

The signs + and − are respectively annexed to Hesvan and Kislev to indicate that the former of these months may sometimes require to have one day more, and the latter sometimes one day less, than the number of days shown in the table,—the result, in every case, being at once determined by the total number of days that the year may happen to contain. An ordinary year may comprise 353, 354, or 355 days; and an embolismic year 383, 384, or 385 days. In these cases respectively the year is said to be imperfect, common, or perfect. The intercalary month, Veadar, is introduced in embolismic years in order that Passover, the 15th day of Nisan, may be kept at its proper season, which is the full moon of the vernal equinox, or that which takes place after the sun has entered the sign Aries. It always precedes the following new year by 163 days, or 23 weeks and 2 days; and Pentecost always precedes the new year by 113 days, or 16 weeks and 1 day.

TABLE VI.—*Hebrew Months.*

Hebrew Month	Ordinary Year	Embolismic Year
Tisri	30	30
Hesvan	29+	29+
Kislev	30−	30−
Tebet	29	29
Sebat	30	30
Adar	29	30
(Veadar)	(...)	(29)
Nisan	30	30
Yiar	29	29
Sivan	30	30
Tamuz	29	29
Ab	30	30
Elul	29	29
Total	354	384

The Gregorian epact being the age of the moon of Tebet at the beginning of the Gregorian year, it represents the day of Tebet which corresponds to January 1; and thus the approximate date of Tisri 1, the commencement of the Hebrew year, may be otherwise deduced by subtracting the epact from

$$\left.\begin{matrix}\text{Sept. 24}\\ \text{Oct. 24}\end{matrix}\right\} \text{after an} \left\{\begin{matrix}\text{ordinary}\\ \text{embolismic}\end{matrix}\right\} \text{Hebrew year.}$$

The result so obtained would in general be more accurate than the Jewish calculation, from which it may differ a day, as fractions of a day do not enter alike in these computations. Such difference may also in part be accounted for by the fact that the assumed duration of the solar year is 6 min. $39\frac{25}{57}$ sec. in excess of the true astronomical value, which will cause the dates of commencement of future Jewish years, so calculated, to advance forward from the equinox a day in error in 216 years. The lunations are estimated with much greater precision.

The following table is extracted from Woolhouse's *Measures, Weights, and Moneys of all Nations*:—

TABLE VII.—*Hebrew Years.*

MAHOMETAN CALENDAR.—The Mahometan era, or era of the Hegira, employed in Turkey, Persia, Arabia, &c., is dated from the flight of Mahomet from Mecca to Medina, which was in the night of Thursday the 15th of July 622 A.D., and it commenced on the day following. The years of the Hegira are purely lunar, and always consist of twelve lunar months, commencing with the approximate new moon, without any intercalation to keep them to the same season with respect to the sun, so that they retrograde through all the seasons in about $32\frac{1}{2}$ years. They are also partitioned into cycles of 30 years, 19 of which are common years of 354 days each, and the other 11 are intercalary years having an additional day appended to the last month. The mean length of the year is therefore $354\frac{11}{30}$ days, or 354 days 8 hours 48 min., which divided by 12 gives $29\frac{191}{360}$ days, or 29 days 12 hours 44 min., as the time of a mean lunation, and this differs from the astronomical mean lunation by only 2·8 seconds. This small error will only amount to a day in about 2400 years.

To find if a year is intercalary or common, divide it by 30; the quotient will be the number of completed cycles and the remainder will be the year of the current cycle; if this last be one of the numbers 2, 5, 7, 10, 13, 16, 18, 21, 24, 26, 29, the year is intercalary and consists of 355 days; if it be any other number, the year is ordinary.

Or if Y denote the number of the Mahometan year, and

$$R=\left(\frac{11\,Y+14}{30}\right)_r,$$

the year is intercalary when $R<11$.

Also the number of intercalary years from the year 1 up to the year Y inclusive $=\left(\frac{11\,Y+14}{30}\right)_w$; and the same up to the year $Y-1=\left(\frac{11\,Y+3}{30}\right)_w$.

To find the day of the week on which any year of the Hegira begins, we observe that the year 1 began on a Friday, and that after every common year of 354 days, or 50 weeks and 4 days, the day of the week must necessarily become postponed 4 days, besides the additional day of each intercalary year.

Hence if $w=1$ indicate Sun.	2 Mon.	3 Tues.	4 Wed.	5 Thur.	6 Frid.	7 Sat.

the day of the week on which the year Y commences will be

$$w=2+4\left(\frac{Y}{7}\right)_r+\left(\frac{11\,Y+3}{30}\right)_w \text{ (rejecting sevens)}$$

$$\text{But, } 30\left(\frac{11\,Y+3}{30}\right)_w+\left(\frac{11\,Y+3}{30}\right)_r=11\,Y+3$$

$$\text{gives } 120\left(\frac{11\,Y+3}{30}\right)_w=12+44\,Y-4\left(\frac{11\,Y+3}{30}\right)_r,$$

$$\text{or } \left(\frac{11\,Y+3}{30}\right)_w=5+2\,Y+8\left(\frac{11\,Y+3}{30}\right)_r \text{ (rejecting sevens).}$$

So that

$$w = 6\left(\frac{Y}{7}\right)_r + 3\left(\frac{11\,Y + 3}{30}\right)_r \text{ (rejecting sevens),}$$

the values of which obviously circulate in a period of 7 times 30 or 210 years.

Let C denote the number of completed cycles, and y the year of the cycle; then $Y = 30\,C + y$, and

$$w = 5\left(\frac{C}{7}\right)_r + 6\left(\frac{y}{7}\right)_r + 3\left(\frac{11\,y + 3}{30}\right)_r \text{ (rejecting sevens).}$$

From this formula the following table has been constructed:—

TABLE VIII.

Year of the Current Cycle (y.)				Number of the Period of Seven Cycles $= \left(\frac{C}{7}\right)_r$						
				0	1	2	3	4	5	6
0	8			Mon.	Sat.	Thur.	Tues.	Sun.	Frid.	Wed.
1	9	17	25	Frid.	Wed.	Mon.	Sat.	Thur.	Tues.	Sun.
*2	*10	*18	*26	Tues.	Sun.	Frid.	Wed.	Mon.	Sat.	Thur.
3	11	19	27	Sun.	Frid.	Wed.	Mon.	Sat.	Thur.	Tues.
4	12	20	28	Thur.	Tues.	Sun.	Frid.	Wed.	Mon.	Sat.
*5	*13	*21	*29	Mon.	Sat	Thur.	Tues.	Sun.	Frid.	Wed.
6	14	22	30	Sat.	Thur.	Tues.	Sun.	Frid.	Wed.	Mon.
*7	15	23		Wed.	Mon.	Sat.	Thur.	Tues.	Sun.	Frid.
	*16	*24		Sun.	Frid.	Wed.	Mon.	Sat.	Thur.	Tues.

To find from this table the day of the week on which any year of the Hegira commences, the rule to be observed will be as follows:—

Rule.—Divide the year of the Hegira by 30; the quotient is the number of cycles, and the remainder is the year of the current cycle. Next divide the number of cycles by 7, and the second remainder will be the Number of the Period, which being found at the top of the table, and the year of the cycle on the left hand, the required day of the week is immediately shown.

The intercalary years of the cycle are distinguished by an asterisk.

For the computation of the Christian date, the ratio of a mean year of the Hegira to a solar year is

$$\frac{\text{Year of Hegira}}{\text{Mean solar year}} = \frac{354\frac{11}{30}}{365\cdot2422} = 0\cdot970224.$$

The year 1 began 16 July 622, Old Style, or 19 July 622, according to the New or Gregorian Style. Now the day of the year answering to the 19th of July is 200, which, in parts of the solar year, is 0·5476, and the number of years elapsed $= Y - 1$. Therefore, as the intercalary days are distributed with considerable regularity in both calendars, the date of commencement of the year Y expressed in Gregorian years is

$$0\cdot970224\,(Y - 1) + 622\cdot5476,$$
$$\text{or } 0\cdot970224\,Y + 621\cdot5774.$$

This formula gives the following rule for calculating the date of the commencement of any year of the Hegira, according to the Gregorian or New Style.

Rule.—Multiply 970224 by the year of the Hegira, cut off six decimals from the product, and add 621·5774. The sum will be the year of the Christian era, and the day of the year will be found by multiplying the decimal figures by 365.

The result may sometimes differ a day from the truth, as the intercalary days do not occur simultaneously; but as the day of the week can always be accurately obtained from the foregoing table, the result can be readily adjusted.

Example.—Required the date on which the year 1362 of the Hegira begins.

$$\begin{array}{r}
970224 \\
1362 \\
\hline
1940448 \\
5821344 \\
2910672 \\
970224 \\
\hline
1321\cdot445088 \\
621\cdot5774 \\
\hline
1943\cdot0225 \\
365 \\
\hline
1125 \\
1350 \\
675 \\
\hline
8\cdot2125
\end{array}$$

Thus the date is the 8th day, or the 8th of January, of the year 1943.

To find, as a test, the accurate day of the week, the proposed year of the Hegira, divided by 30, gives 45 cycles, and remainder 12, the year of the current cycle.

Also 45, divided by 7, leaves a remainder 3 for the number of the period.

Therefore, referring to 3 at the top of the table, and 12 on the left, the required day is Friday.

The tables, page 670, show that 8th January 1943 is a Friday, therefore the date is exact.

For any other date of the Mahometan year it is only requisite to know the names of the consecutive months, and the number of days in each; these are—

Muharram, ...	30	Shaaban, ...	29
Saphar, ...	29	Ramadân, ...	30
Rabia I., ...	30	Shawall, ...	29
Rabia II., ...	29	Dulkaada, ...	30
Jomada I., ...	30	Dulheggia, ...	29
Jomada II., ...	29	and in intercalary years	30
Rajab, ...	30		

The ninth month, Ramadân, is the month of Abstinence observed by the Turks.

The Turkish calendar may evidently be carried on indefinitely by successive addition, observing only to allow for the additional day that occurs in the bissextile and intercalary years; but for any remote date the computation according to the preceding rules will be most efficient, and such computation may be usefully employed as a check on the accuracy of any considerable extension of the calendar by induction alone.

The following table, taken from Woolhouse's *Measures, Weights, and Moneys of all Nations,* shows the dates of commencement of Mahometan years from 1845 up to 2047, or from the 43rd to the 49th cycle inclusive, which form the whole of the seventh period of seven cycles. Throughout the next period of seven cycles, and all other like periods, the days of the week will recur in exactly the same order. All the tables of this kind previously published, which extend beyond the year 1900 of the Christian era, are erroneous, not excepting the celebrated French work, *L'Art de vérifier les Dates*, so justly regarded as the greatest authority in chronological matters. The errors have probably arisen from a continued excess of 10 in the discrimination of the intercalary years.

M. restituti Explicatio*, Rome, 1603; *L'Art de vérifier les Dates;* Lalande, *Astronomie*, tom. ii.; *Traité de la Sphère et du Calendrier*, par M. Revard, Paris, 1816; Delambre, *Traité de l'Astronomie Théorique et Pratique*, tom. iii.; *Histoire de l'Astronomie Moderne; Methodus technica brevis, perfacilis, ac perpetua construendi Calendarium Ecclesiasticum, Stylo tam novo quam vetere, pro cunctis Christianis Europæ populis, &c.*, auctore Paulo Tittel, Göttingen, 1816; *Formole analitiche pel calcolo della Pasqua, e correzione di quello di Gauss, con critiche osservazioni su quanto ha scritto del Calendario il Delambri*, di Lodovico Ciccolini, Rome, 1817; E. H. Lindo, *Jewish Calendar for Sixty-four Years*, 1838; W. S. B. Woolhouse, *Measures, Weights, and Moneys of all Nations*, 1869. (T. G.—W. S. B. W.)

CALENDER, a mechanical engine employed for dressing and finishing cloths and various descriptions of fabrics, preparatory to sending them into the market. It is also used by calico-printers to prepare the surface of their cloths for the operations of printing. The first object of calendering is to produce in the cloth as perfect extension and smoothness of surface as can be attained,—so that no wrinkle or doubled folding may remain in it. The second end attained by the calendering of cloth is the compression of the yarn or threads of which the texture is composed, which in some degree divests them of their cylindrical shape, and reduces them to a degree of flatness, which, by bringing them more closely into contact with each other, gives to the fabric a greater appearance of closeness and strength than it would otherwise possess. The operation of the calender also improves the superficial appearance, by flattening down all knots, lumps, and other imperfections, from which no material from which cloth is fabricated can ever be entirely freed during the previous processes of spinning and weaving. And, thirdly, in certain fabrics it is desirable that cloth should receive, by means of friction, an additional lustre or polish, which is distinguished by the appellation of glazing. For the accomplishment of these objects the agencies on which the calenderer has to rely are moisture, heat, pressure, and friction, and these he variously combines to produce many different effects.

The term calender, which really means only the chief mechanical engine employed, gives the general name to the finishing establishments where all the varied operations of cloth-lapping are carried on; and it is as usual to say that goods are *packed* as that goods are *dressed* at a calender. The common domestic smoothing-iron may be regarded as a form of calendering utensil; as is also the old-fashioned domestic mangle, which consists of a cylinder applied to a plane, upon which it is rolled backward and forward, until some degree of smoothness is produced by this reciprocating motion. A form of mangle, consisting of an enormously heavy cylinder, which is worked forwards and backwards over a plane surface, is still used in calendering establishments for the finishing of very heavy linens and similar goods.

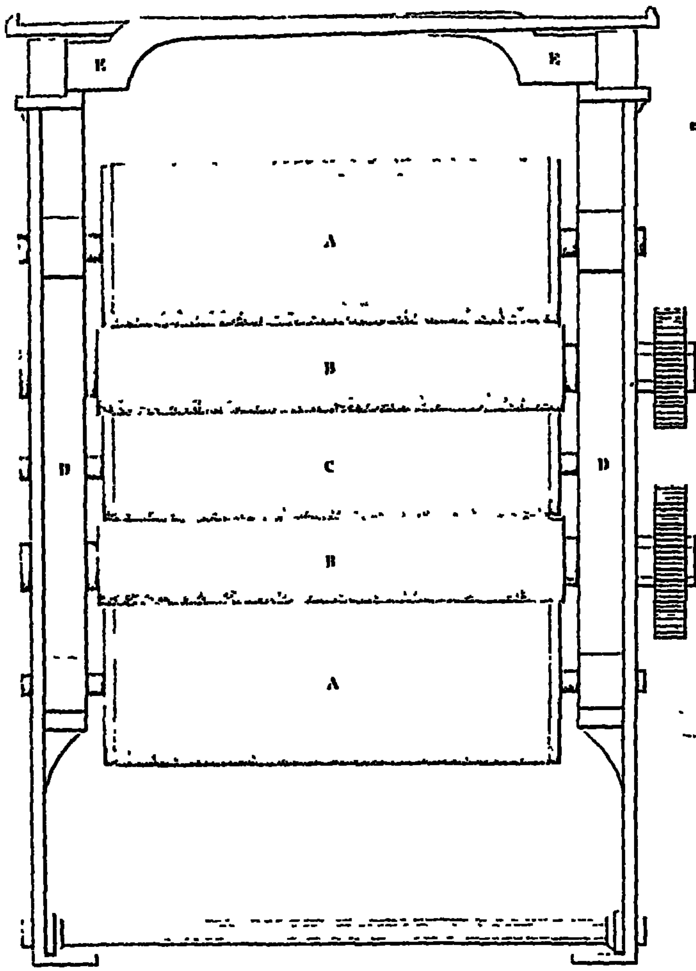
The smoothing calender completes the substitution of cylindrical for plane surfaces, all the parts which operate upon the cloth being of that form. This ingenious engine, which was introduced into Britain from Flanders and Holland during the persecution of the Huguenots, has, since its introduction and adoption, undergone no very material or important alteration or improvement in point of theoretical principle; nor, until the extension of the cotton manufacture had introduced a general spirit of mechanical improvement, were any great advances made in the practical applications of it

Calenders are constructed with from two to five rollers or cylinders, technically termed "bowls,"—three or five-bowl calenders being most frequently employed. The materials of which these cylinders are made are wood, compressed paper, and metal, such as chilled cast-iron, brass, or copper. They are variously arranged in relation to each other, and as mechanical arrangements are required—1st, for varying pressure; 2d, for applying heat within a metal bowl from steam, hot iron, or burning gas; and 3d, for varying the rate of motion of a pair of the bowls so as to produce friction—the gearing of a calender is somewhat complex. Commonly a three-bowl calender has an upper and under cylinder of paper, the central one being of metal, and in such an implement either two pieces may pass through at the same time, or one piece may receive two pressures. An ordinary five-bowl calender has the first, third, and fifth cylinders of paper, the intermediate being of metal, and here four successive pressures may be given. Fig. 1, Plate XXXII., is an elevation of a five-roller calender for finishing cloth. A, A are two paper rollers, of 20 inches diameter each. B, B are two cast-iron cylinders, externally turned until perfectly smooth; their diameter is 8 inches, allowing the substance of iron to be 2 inches, and leaving a perforation of 4 inches diameter. C is a paper roller of 14 inches diameter; D, D is the framing of cast-iron for containing the bushes in which the journals of the rollers revolve; E, E are two levers by which the rollers are firmly pressed together while the cloth is passing through.

Fig. 2 is an end view of the same calender, with the wheels for glazing cloth. The wheel on the upper cylinder is 10 inches diameter, the wheel on the under cylinder is 13 inches diameter; they are connected by the wheel F, which communicates the speed of the upper cylinder, so that the wheel on the under cylinder being nearly one-third of an inch more in diameter, the difference of their motions retards the centre paper roller, by which means the upper cylinder passes over the cloth one-third faster than the cloth passes through the calender, and polishes it in consequence.

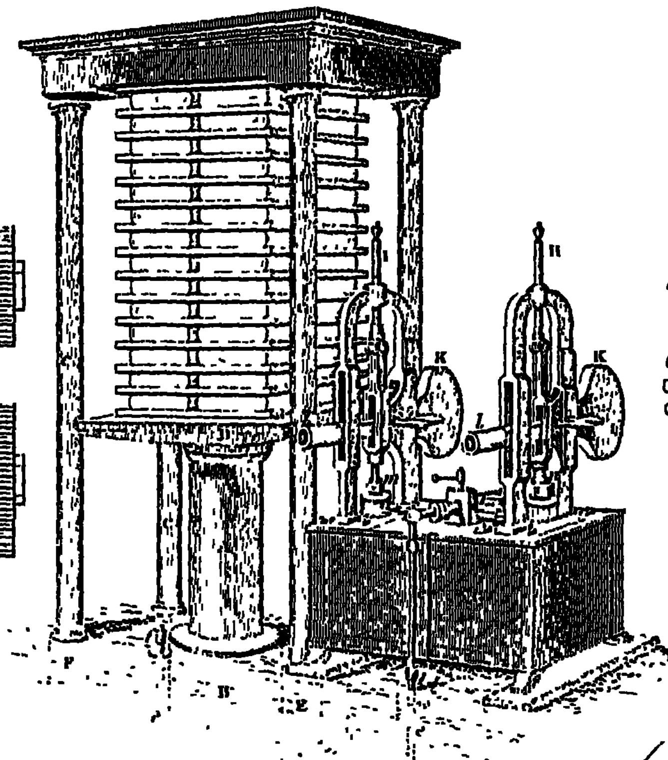
The construction of paper or pasteboard rollers for calenders is a process of great interest and importance. The frequent heating and cooling to which the apparatus is subject necessarily produces warping and splitting in wooden bowls, which are thereby rendered useless, but the substitution of paper afforded a radical cure for these defects as well as a collateral advantage arising from its being susceptible of a much higher degree of superficial polish, which is always transferred to the cloth. In the construction of paper cylinders an axis or journal of malleable iron and two circular plates of cast-iron of the same diameter as the cylinder to be made are, in the first place, provided. A plate is secured on one end of the journal. The entire space between the two iron plates is then to be filled with circular pieces of paper or pasteboard, exceeding by about 1 inch in diameter the iron plates, and having each a correspondent perforation, through which the iron journal passes. A cylinder is thus formed, the substance of which is of paper locked together by plates of iron at the extremities, and susceptible of immense compression which it receives in a hydraulic press. After undergoing this preparation, the cylinder is exposed to strong heat in a confined apartment in which the paper contracts and becomes loose. It is again put into the press, more sheets of paper are added, and this process goes on till the cylinder has gradually acquired the requisite compression. It is then re-exposed to the ordinary temperature of the atmosphere, and by its re-expansion presents a body almost remarkably compact, its specific gravity in this state being greater than even that of silver.

Fig. 1



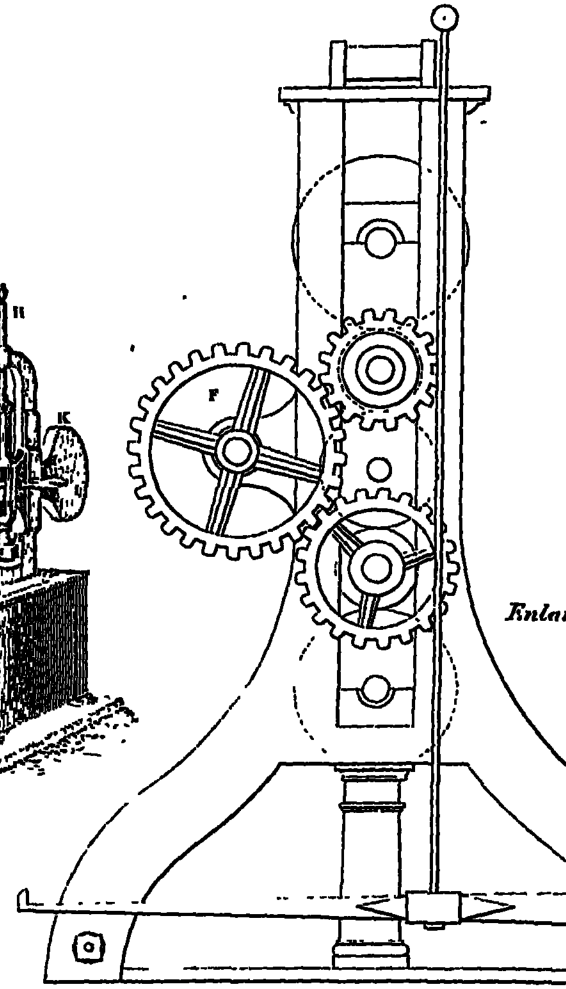
Five-bowl Calender - front elevation

Fig. 3.



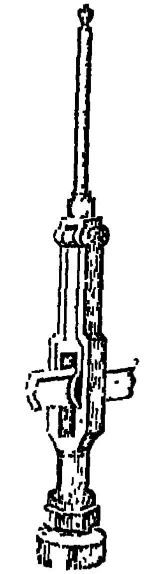
Hydraulic Press

Fig. 2.



Five-bowl Calender, - side elevation.

Fig. 4.



Enlargement of H & L
Fig. 3.

The only operation now required is that of turning its superficies until correctly cylindrical; and this is a work of immense labour and patience.

For dressing muslins, gauzes, lawns, and other goods of a light kind, a smaller species of calender is employed. It consists of only three cylinders of equal diameter (generally about 6 inches), and is easily moved by a common winch or handle. The middle cylinder is iron, and the others are of wood or pasteboard. All the cylinders are of equal diameter, and are moved with equal velocities by means of small wheels. This machine is always used in a cold state.

By means of the calender, also, is produced the waved or watered surface, known as *moiré* among the French, and best seen in the silk textures called moire antique, and in woollen moreens. The effect is produced in a variety of ways, the principal method employed consisting of passing two webs laid above each other through the calender at the same time. The threads of the web not running perfectly parallel to each other are at some places superimposed, and at other points they fit into alternate spaces,—the result being that at the places where the threads press directly on each other a higher gloss is produced, which gives the watered appearance to the texture. Watering is also effected on a single thickness of material by moving the web to the right and left as it enters the calender, and thus varying the direction in which it travels over a bowl on which there are a series of engraved lines running in a parallel direction. Embossed patterns, or imitations of the grain of leather, &c., for bookbinders' cloth, are produced by means of a calender having a bowl of brass or other metal on which the pattern is engraved. When a paper cylinder is used along with an embossing cylinder, the paper must be turned into such exact proportion to the embossed bowl that it will repeat the pattern accurately on its circumference, so that the depressions on the one bowl always fit accurately into the elevations on the other. For many purposes a covering of leather, felt, or lead is used for the cylinder which works against that on which the pattern is engraved.

Goods after passing through the calender are folded, either by machinery or on long pins by hand-working into a variety of forms according to their nature and destination, and when so folded they are submitted to a very powerful compression either in a screw-press or in an hydraulic press.

Fig. 3, Plate XXXII., is a perspective view of an hydraulic press. A is the piston, 8 inches diameter, working in the cylinder B, and kept water-tight by passing through a collar of leather; D, a cast-iron plate raised by the piston A, between which and the entablature E, E the goods to be pressed are laid; C, C, C, C, four malleable iron columns, $2\frac{3}{4}$ inches diameter, having screwed ends, with nuts, by which the entablature and the base F, F are firmly connected together; G, a cistern for holding water to supply the two force-pumps H and I, the largest of which has a piston $1\frac{1}{2}$ inch diameter, and the other one of $\frac{1}{2}$ inch diameter, which is used to give the highest pressure; K, K, weights to balance the pump-handles which fit into the sockets at *l*, *l*. The pistons of the force-pumps are made water-tight by collars of leather, kept in their place by the screwed pieces *m* and *n*. *e*, *e*, *e* is a pipe communicating with the pumps and the large cylinder B; there is a stopcock at *f*, which shuts this communication when required.

Fig. 4 is an enlarged view of the force-pump piston, to show the method of keeping the rod parallel.

An illustration of a glazing calender as used by bleachers and calico-printers, with further details as to finishing processes, will be found under Bleaching. See also Calico-Printing.

CALEPINO, Ambrogio (1435-1511), an Augustine monk, born at Bergamo in 1435, was descended of an old family of Calepio, whence he took his name. He devoted his whole life to the composition of a *polyglott dictionary*, first printed at Reggio in 1502. This gigantic work was afterwards augmented by Passerat and others. The most complete edition, published at Basel in 1590, comprises no fewer than eleven languages. The best edition is that published at Padua in seven languages in 1772. Calepino died blind in 1511.

CALHOUN, John Caldwell (1782-1850), a leading politician of the United States, was grandson of an Irish Presbyterian, who founded Calhoun settlement, in the district of Abbeville, South Carolina. It was there that John Calhoun was born in 1782. For some years he assisted his widowed mother in the management of her farm, but at the age of eighteen he commenced to study for the bar. He graduated with honours at Yale College, and spent eighteen months at Litchfield, at that time the only law school in the country. He then returned to practise in his native district of Abbeville. While there, in June 1807, the searching of the Chesapeake having aroused strong feeling in America, Calhoun drew up for a public meeting a resolution expressive of indignation against Great Britain, and supported it in a speech of such power that he was soon after elected a member of the legislature, and in November 1811, became member of Congress, where he continued to be an enthusiastic and prominent adherent of the war party. For seven years (commencing with 1817) he acted with credit as secretary of war under Monroe; in 1825 he became Vice-President of the United States under J. Quincy Adams; and in 1829 he was re-elected under General Jackson. He now began to be looked upon as champion of the South; and, though he had supported the protective tariff of 1816, he became an eager advocate of free-trade,—that policy being, even popularly, recognized as specially advantageous to the cotton-growing States. He is, however, best known as a strenuous defender of slavery, and as the author of a doctrine to which the Civil War may be traced,—the doctrine of "nullification," according to which each State has the right to reject any act of Congress which it considers unconstitutional. This view was in 1829 adopted by the legislature of his native State, and drawn up in a document, mainly prepared by Calhoun, which was known as the "South Carolina Exposition," and which was approved by Virginia, Georgia, and Alabama. In 1832 the legislature of South Carolina carried the theory into practice by passing laws nullifying the obnoxious tariff of that year; but its opposition was crushed by the firmness of General Jackson, who declared that he would resort to force, if necessary. The most important of the other political acts of Calhoun are his defence of the right of veto which belongs to the president, his advocacy of the annexation of Texas, and his maintenance of the cause of peace, when war with Great Britain was threatened by the claims of the United States to Oregon. He died at Washington on the 31st March 1850. His works, with memoir, were published posthumously in 6 vols. in 1853-4, by Richard K. Cralle, who had been his amanuensis. They include a dissertation *On the Constitution and Government of the United States*; and from this book we learn that he advocated the election of two presidents, one by the free and another by the slave States, the consent of both of whom should be essential to the passing of any law. Calhoun's speeches were always directly to the point, clear, and forcible, while he seldom indulged in the imaginative or purely rhetorical. The integrity and worth of his character have been spoken of in the highest terms even by political opponents.

CALICO-PRINTING

CALICO-PRINTING is the process of imprinting on textile fabrics patterns of one or more colours on a white or coloured ground. Though, as the name implies, the art is directed primarily, as it is by far most extensively, to calico or cotton textures, the same methods of ornamentation are also employed for certain woollen, linen, and silk fabrics, and the process of printing is also applied to unwoven yarns, notably in the case of worsted yarns intended for use in the weaving of tapestry carpets. But as certain of the processes employed for printing cotton agree essentially with those used for woollen and silk fabrics, it will be unnecessary here to refer specially to any other than the methods employed in the printing of calico proper.

There is a curious passage in *Pliny's Natural History* (xxxv. 42), from which it is evident that calico-printing in his time (the 1st century) was understood and practised in Egypt. The following is a translation of this passage:—

"There exists in Egypt a wonderful method of dyeing. The white cloth is stained in various places, not with dye-stuffs, but with substances which have the property of absorbing (fixing) colours. These applications are not visible upon the cloth; but when the pieces are dipt into a hot caldron containing the dye, they are drawn out an instant after dyed. The remarkable circumstance is, that though there be only one dye in the vat, yet different colours appear on the cloth; nor can the colours be afterwards removed. A vat which would of itself only confuse the colours on cloth previously dyed, in this way imparts several colours from a single dye-stuff, painting as it boils." It is evident enough that the substances employed to stain the cloth, as Pliny expresses it, were different mordants, which served to fix the dye upon the cloth. Thus if we suppose certain parts of a piece of cotton cloth to be impregnated with alumina, and the cloth afterwards dyed with madder, after the clearing, those parts only impregnated with the mordant would retain their red colour, while the remaining parts will continue white.

The general opinion is, that this ingenious art originated in India, and from that country made its way into Egypt. Whether this notion be well or ill founded, it is certain that calico-printing was known and executed by the Indians at a very early period. Their colours were beautiful and fast, and the varieties of pattern and the number of colours which they knew how to fix on different parts of the cloth gave to their printed calicoes a beauty and a value of no ordinary kind; but their processes are so tedious and so clumsy that they could be put in practice only where labour was exceedingly cheap.

It was not till towards the close of the 17th century that calico-printing was introduced from India into Europe, having probably been practised first in Holland, to which country a knowledge of the art was carried by the Dutch East India Company. Evidence exists which shows that calico-printing was commenced in the neighbourhood of London so early as the year 1676, and there the art continued long to be practised. In 1738 it extended to Scotland, and took firm root in the country around Glasgow, but it was not till 1764 that it was introduced to what is now its chief centre, Lancashire. The extent of the industry in Great Britain at the present day is probably unequalled by the combined production of all other nations of the world. The other European countries where the art is prosecuted to any considerable extent are France, Switzerland, and Germany, to the last of which the annexation of the Rhine Provinces, consequent on the war of 1870-1, has added a famous centre of the industry. The art is also extensively cultivated in the United States, while Oriental communities still continue to prosecute it in their own peculiar fashions.

In Europe the art has been in a great measure created anew. By the application of machinery, and by the light thrown on the processes by the progress of chemistry, the tedious methods of the Indians have been wonderfully simplified; and the processes are remarkable for the rapidity with which they are now executed, and for the beauty, fastness, and variety of the colours which are applied on the surface of cotton. So great have been these improvements, that at the present time in Manchester a piece (25 yds.) of calico can be printed in the short period of one minute; and the quantity of calicoes printed in Great Britain in one year cannot measure less than three quarters of a million of miles, seeing the exports alone of printed cotton piece goods during the year 1874 amounted to 1,003,101,107 yards, of a value of £19,602,706, an amount exceeded by 140,000,000 yards in 1872.

Grey calico is prepared for printing by an elaborate process of BLEACHING, for the details of which the reader is referred to the article under that head, vol. iii. p. 811. The bleached cloth previous to printing is generally passed through a shearing machine, which removes from its surface the fine downy pile and short threads, thus preparing a smooth uniform surface capable of taking a sharp distinct impression from the engraved printing-blocks or rollers. The printing processes which follow are exceedingly complex and varied, demanding for their proper execution an extended range of chemical knowledge and mechanical ingenuity; and as commercial success depends largely on the tasteful and harmonious colouring of patterns, no little artistic ability and discrimination is required for the efficient superintendence of such works.

There are two modes of printing,—namely, *block-printing* and *machine-printing*. The former has been practised from time immemorial; the latter is a modern invention, and originated after the introduction of the art of printing into Great Britain. In the case of block-printing the figure intended to be communicated to the cloth is cut out upon a block of sycamore, the parts which are to make the impression being left prominent, and the rest of the block cut away, just as practised for wood engravings. When the figure is too complicated, and the lines too fine, to admit of being cut in wood, it is made by means of small pieces of copper, which are very ingeniously driven into the block, and the interstices are filled up with felt.

By means of a modern invention several colours may be applied at once on the cloth by means of one block. The machine used for this purpose, which is called a "toby," consists of a box divided into several compartments filled with various colours, which are in communication through tubes with bottles filled with the same colours; and by means of a gentle pressure the colouring fluid in each of the compartments of the machine is propelled through the felted cloth which covers each compartment. The block, being pressed against the cloth, takes the colour which is to be conveyed to the white calico by the block-printer.

By Continental printers an intricate apparatus for printing called the Perrotine, from the name of its inventor, is employed; but it has never been introduced to any considerable extent in England. In this machine the intended figures are engraved upon a flat copper plate of about a square yard or more in size. Upon this plate the

colour to be applied is spread. The plate is then pulled backwards, the excess of colour being removed by a "doctor," and the colour remaining on the engraving is then printed on the white cloth.

Printing is now almost universally accomplished by means of cylinder machines, in which the impression is given by one or a series of engraved copper cylinders; a different cylinder being required for each separate colour or shade in the pattern. The cylinders are made about 3 feet 6 inches long and 6 inches in diameter; and in establishments of any considerable extent many thousands of these are kept in stock, involving an enormous outlay of capital. There are three different methods in practice for engraving patterns or portions of patterns on the cylinders. In the first, the "die and mill" process, a cylindrical steel die is engraved with the pattern, which is afterwards transferred to a "mill" or cylinder of soft steel. The pattern on the mill is in relief, and after hardening it is by pressure impressed into the copper roller. The diameter of the mill is such that the repeats of the pattern fit with the utmost precision when transferred to the copper roller. The "die and punch" process is a modification of the foregoing, in which small patterns are impressed on the copper cylinder by means of a punch which has the pattern in relief transferred to it from a sunk steel die. The third process by which engraved rollers are prepared is by the aid of the pentagraph, a most complex and ingenious machine, with which by the movement of a single tracer in the deep lines of an enlarged pattern cut in a zinc plate, these lines are reproduced on the original scale, traced at five different places through a coating of bituminous varnish on the surface of the cylinder. After the engraving is complete, the cylinder is placed in a bath of dilute nitric acid, by which the pattern is bitten in along the surfaces of the metal exposed by the scratching of the pentagraph points.

Calico-printing machines are arranged to print with any number of such cylinders, from one up to as many as twenty; but in practice few machines carrying more than eight cylinders are employed. The accompanying diagrammatic section (fig. 1.) illustrates the arrangements necessary for printing one colour, and each of the separate colours on a machine is similarly mounted round the periphery of the central bowl or cylinder *a*. Against this central bowl *a* the engraved copper cylinder *b* presses, and between them the cloth to be printed and a thick cloth or blanket pass. The cylinder is supplied with the printing material by means of a furnishing roller *c*, which revolves in the colour-box *d*. The superfluous colour is removed from the cylinder by means of the colour doctor *e*, a steel blade which fits closely to the surface of the roller, and removes all colour except that which fills the engraved portions. The lint doctor *f* similarly removes all impurities which adhere to the roller after it has communicated its impression to the cloth. Fig 2 shows the elevation of a six-colour machine by Messrs Mather and Platt of Manchester, to whose courtesy we are indebted for illustrations of the most recent and approved forms of apparatus. The essential parts of this machine consist of the central iron bowl or cylinder A, and the six radiating arms B, each of which holds in position an engraved roller colour-box, &c., as shown in diagram fig. 1. By means of screws and other fine mechanical adjustments the pitch of each roller can be arranged so that its particular colour falls on the proper place with the utmost exactitude, producing a perfect pattern. In printing, the white calico is batched at C, and the cloth D passes inwards over tension rails, proceeding round the periphery of the bowl A, receiving from each roller B a separate colour or mordant, and issuing at D', printed and ready for the further processes to be hereafter detailed. Around the central bowl A are lapped, for the sake of elasticity, several folds of cloth. Between the central bowl and the cloth to be printed there passes, 1st, an endless band of cloth or blanket, seen entering at E and issuing at E'; and 2d, a "grey back" or web of unbleached calico, used to keep the blanket clean, which enters at F and issues at F'.

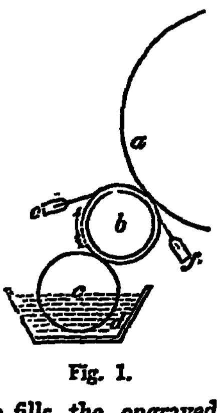


Fig. 1.

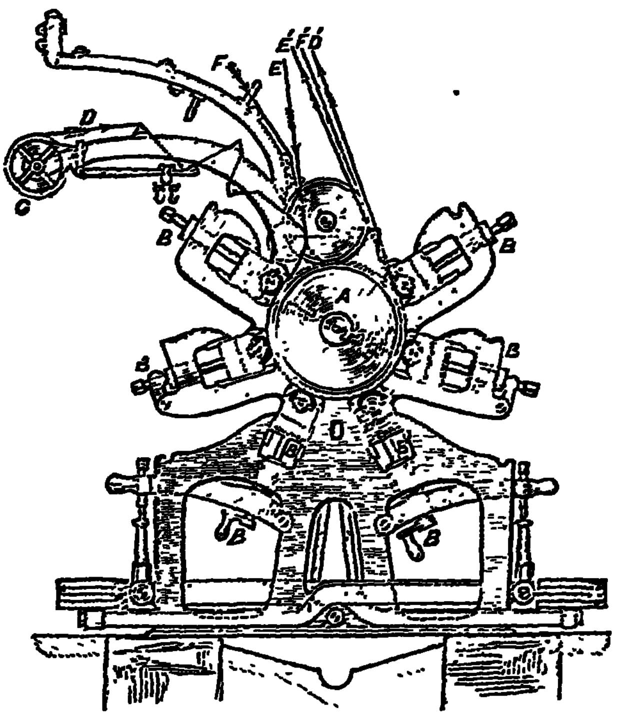

FIG. 2.—Cylinder Printing-Machine—six colours.

By whatever mechanical means the printing is performed, whether by hand-block, perrotine, or cylinder machine, the effect is precisely the same, and the colours or mordants employed are in all cases alike. The substances to be printed on the surface of the calico have to be brought to a proper consistency for printing by means of thickeners, with which they are mixed up in colour pans. Although these are only mechanical agents, it is found in the practical operation of printing that particular thickeners are more suitable for certain colours or mordants than others, and the printer is guided by experience in selecting that thickening adjunct which gives the clearest impression. Among the numerous thickeners available, those most commonly employed are wheat flour and starch, potato starch, dextrin or British gum, and gum-senegal or other varieties of gum-arabic. The mordant or the colour and its appropriate thickeners are placed in a range of colour pans, in which the materials are thoroughly incorporated. A pair of these pans (one in section), as constructed by Messrs Mather and Platt, embracing the most recent and approved appliances, is shown in fig. 3. In the cut, A represents the driving pulleys, B the driving shaft, wheels, and catch-box, *c* wheels for giving a rotary motion to the brass stirrers *d*. E is the colour pan, of copper, double cased, made to swivel on centres or pivots f^1 and f^2. Through f^1 water and through f^2 steam are supplied to the space between the outer and inner body of the pan for the purpose of boiling and cooling down the contents of the pan alternately as required. The supply of steam or

of water to these pipes is regulated by the tap g. H is the framing, J stands, with the necessary appliances for turning over the pans to empty their contents, K a pipe and swivel tap for supplying water to the pans. L is the main steam pipe to f^1, m the water pipe to f^2 and K, and n and o are taps for washing out and for condense water respectively.

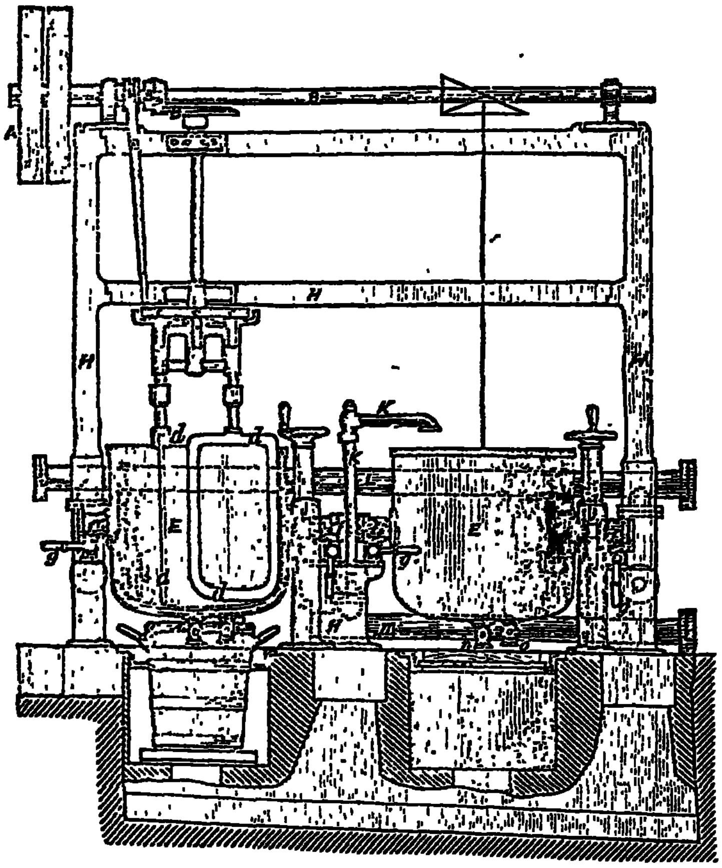

Fig. 3.—Colour Pans.

The variety of methods by which colours are produced on calicoes is almost endless, and the processes employed, both chemical and mechanical, as well as the tinctorial agents used, are also very numerous and diversified. The processes are in practical works generally classified under the heads of numerous different styles, combinations of several of which are frequently employed in the production of a single pattern It is at once impossible and unnecessary to enter into details of these various styles here; but they all resolve themselves into a few general groups, under which heads they will be briefly treated of. In certain styles a mordant, or chemical substance, which possesses an affinity for both the cloth and the dye-stuff, is the substance printed in the cylinder machine, and the calico has to undergo a subsequent process of dyeing by which those portions of the cloth which received the mordant are alone permanently dyed Again, the colour-box may contain all the ingredients necessary for the production of the colour, but to develop it in the fibre it is necessary to expose the printed cloth to the oxidizing influence of the atmosphere, or otherwise produce an oxidation of the dye-stuff by which the colour is developed and fixed. By a third process the colour is prepared and applied direct to the cloth mixed with some agent which, under the influence of heat and moisture, either mechanically attaches or chemically precipitates the colour in the fibre. And a fourth process, which may be regarded as a modification of the third, consists of mixing the dye with powerful mordanting substances, which, after printing, are merely dried, the mordant volatilizing sufficiently to fix the dye, not very fast, on the cloth. There are thus these four divisions—

I. Dye colours.
II. Oxidation colours.
III. Steam colours.
IV. Spirit colours.

Along with these different methods patterns are also produced and modified by means of substances applied to cloth already dyed or printed in order to remove the colour from certain portions of it which are either intended to remain white, or to receive some other colour afterwards. These substances are known as "discharges," and examples of their action are seen in printed Turkey reds and bandannas.

Sometimes a substance is applied to cloth before it is dyed, in order to prevent the indigo, or any other colour, from being fixed on those parts to which it is applied, that they may remain white, or be afterwards made to receive other colours. Substances possessed of this property are called "resists."

Dye Colours.

Under this head are included prints prepared by printing the pattern in one or more mordants—substances which have an affinity for the fibre on the one hand and the dye-stuff on the other. The mordanted cloth is subsequently submitted to a process of dyeing, when the dye-stuff is fixed only on such parts of the cloth as have been impregnated with the mordant. By using more than one mordant, by mixing them, or by employing the same at different degrees of strength, a variety of shades or colours is produced in the process of dyeing with one dye-stuff.

Mordants.—The principal mordants employed for dye colours are the following :—

1. *Red Liquor.*—The acetate of alumina mordant or "red liquor" of the calico-printer is prepared by partly decomposing alum, held in solution by impure acetate of lime, commonly called pyrolignite of lime; sulphate of lime precipitates and acetosulphate of alumina is thus obtained. Red liquors thus prepared have a specific gravity of 1·08, and are composed as follows :—

Composition of four red Mordants per Gallon.

Substances.	Mordant A.		Mordant B.		Mordant C.		Mordant D.	
	grains.	oz. grs	grains.	oz. grs.	grains.	oz. grs.	grains.	oz. grs.
Alumina ..	1680 0	3 367	1830 0	4 80	1239 0	2 364	2164 4	4 414
Sulphuric acid	2642 5	6 20	2800 0	6 175	3017 0	6 392	1664 6	3 352
Acetic acid	3369 8	7 307	3970 0	9 32	1281 7	2 406	3679 2	8 179
Ammonia and water	674 1	1 236	910 0	2 35	693 1	1 255	...	...

In the manufacture of "red liquor," sulphate of alumina is frequently substituted for alum, and acetate of lead for pyrolignite of lime.

2. *Iron Liquor.*—The oxides of iron are much used as mordants, either in the state of protoxide or peroxide. The salt most employed is the impure pyrolignite of protoxide of iron, which is prepared either by decomposing green copperas with pyrolignite of lime, or by placing in large vats pyrolignous acid and old iron, when, after a few months, the iron, which is gradually oxidized, dissolves in the acid, and gives rise to pyrolignite of protoxide of iron. This valuable mordant is thickened with calcined farina, flour, starch, or gum, and applied on the calico. After being exposed for a few days in a moist atmosphere, it loses a part of the acid, and becomes partially peroxidized. Pyrolignite of iron of the specific gravity of 1·05 gives a black with madder and several "tannin" substances. Various shades of purple are obtained by adding different proportions of water to the mordant previously to applying it to the cloth; and various shades of chocolates are produced by mixing this with the alumina mordant previously described, and then dyeing also with madder.

These two mordants are the principal employed for madder colours; but several others are employed for special shades. Among these may be enumerated the aluminate

of soda or alkaline pink (used as a mordant when it has to act as a resist for another colour such as aniline black), and acetates of chromium, copper, tin, and other metals.

Dye Colours.—The principal dye colour is madder or some of its derivatives, including artificial alizarin, the dyeing principle of madder obtained synthetically from anthracene. Madder is the root of a plant, *Rubia tinctoria*, a native of Central Asia, but introduced and extensively cultivated in south Europe, especially at Avignon in France. For the purposes of the calico-printer, madder-root is prepared by simply grinding, or in the form of flowers of madder (*fleurs de garance*), of garancin, of garanceux, or of alizarin. Fleurs de garance is powdered madder deprived of its soluble constituents and redried, whereby the tinctorial strength of the preparation is increased nearly one-half. Garancin is prepared by boiling powdered madder in sulphuric acid; garanceux is spent madder similarly prepared; and alizarin, the chief tinctorial principle of madder, is obtainable from garancin by the action of superheated steam. Among the chemical principles of tinctorial value yielded by madder there is, besides alizarin, an allied substance named purpurin. Alizarin of precisely similar composition and behaviour is now artificially made from anthracene, one of the products of coal-tar, and purpurin also is obtainable by the oxidation of artificial alizarin. By chemical agency the essential ingredients of madder are thus now produced in a cheaper, more convenient, and more effective form than it was formerly possible to extract them from the cultivated root. Madder extract, garancin, and alizarin dye heavier and more brilliant colours than madder, and they require less soaping or other treatment to clean the whites after dyeing. Madder extract and artificial alizarin are also used as steam colours.

We may now briefly follow the stages in printing a madder style, taking for example a calico printed in four 'colours' (the technical name for whatever is printed by the machine, whether mordant or dye), with a padding or blotch of weak iron liquor. In this case the mordants or colours are—

Black from strong solution of iron liquor.
Purple from weak solution of iron liquor.
Red from solution of red liquor.
White resist of solution of citric acid (lime juice).
Purple pad or cover of weak iron liquor, which falling on the acid resist forms a soluble ferric citrate.

Drying.—The cloth after receiving these impressions passes into a drying apparatus, generally a closed chamber, highly heated by radiation from steam-chests of cast-iron. Through such a chamber the cloth passes up and down over numerous rollers, traversing a long distance before it emerges dry and ready for the next process. Another means of drying, employed in some of the best establishments, such as Thornliebank, is by passing the cloth round a long series of revolving steam cans or cylinders, the metallic surface of which is covered with felt. Recently a most effective system of drying has been introduced, which consists of forcing a strong current of heated air through an enclosed chamber by the action of a fan, connected with which is an apparatus filled with pipes, through which the air passes, while surrounding the pipes is a steam space. By this plan any temperature may be obtained, and the current of air adjusted by the speed of the fan.

Ageing.—From the drying apparatus the goods pass to the ageing room, a lofty and spacious chamber (fig. 4), where they are exposed to the combined influence of heat and steam. The pieces pass, as shown by the arrows, up and down over rollers from end to end of the room, travelling over a long space, for twenty minutes or thereby. The atmosphere is rendered moist by jets of steam blowing from pipes *a*, *a*, and hot by radiation from the same and other steam pipes. A difference of four degrees is maintained between the dry and wet thermometers; the readings average 80° and 76° Fahr. The cloth takes up about 5 per cent. of its weight of moisture in its passage, and as it issues at the further end of the apartment, it is piled up in loose bundles, and so left for two or three days in a warm moist atmosphere. The object of the operation of ageing is to precipitate the mordants in the fibre of the cloth, they in the meantime being partly decomposed with the disengagement of abundant fumes of acetic acid. The practical development of the modern process of ageing is due to the scientific ingenuity of the late Mr Walter Crum of Thornliebank, the method previously practised having been tedious and uncertain, depending upon variable states of the weather.

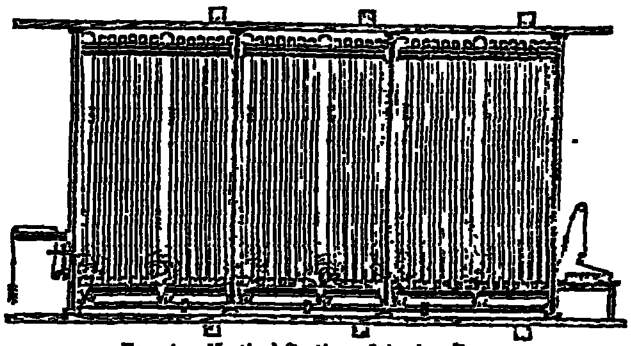

Fig. 4.—Vertical Section of Ageing Room.

Dunging.—It is next necessary to remove any superfluous uncombined mordant which may be on the cloth, and to take away the thickening agent with which the mordant was printed. These objects are accomplished by passing the goods through hot water, in which it was formerly the practice to dissolve cow's dung, hence the name; but now some of the numerous dung substitutes are chiefly used, the principal of which are the silicate and the arseniate of soda. The first operation in dunging is to pass the pieces through the "fly dunging" apparatus,—a cast-iron trough with rollers top and bottom,—by which the cloth is made to pass, in the open state, through the hot solution. This operation fixes the mordant in the fibre and prevents it from spreading to unmordanted parts of the cloth in the subsequent washing and dyeing operations to which it is subjected. Immediately after the fly-dunging the goods are washed and submitted to a second dunging, this time in a different kind of apparatus, through which they are passed in a coil or loose rope form. They are then thoroughly washed at a machine to remove the last traces of thickening matter and all uncombined ingredients.

Dyeing.—At this point the goods are ready for dyeing, the most important process in the whole series of operations. The dye-beck or vat, one form of which is shown in longitudinal and transverse section in fig. 5, consists of

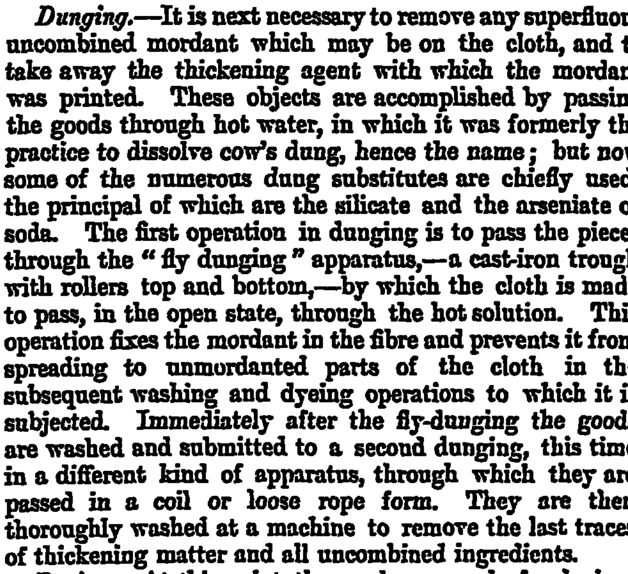

Fig. 5.—Sections of Dye Vat.

an iron cistern or trough A, into which the dyeing solution is introduced. Running along the whole length of the

trough is a steam pipe *b*, perforated at intervals, by which the requisite heat for the dyeing operation is raised and maintained. Sloping upward from the steam pipe is a perforated diaphragm of iron or midfeather *c*, and mounted on a strong framework over the trough is the winch D, which by its revolutions, effected by spur wheels, keeps the cloth moving down and up continuously into and out of the trough. A peg rail *e* runs along the length of the trough, which keeps the pieces from becoming entangled in their course. The figure shows the course of a chain of pieces being dyed on the endless system, in which about twenty-five pieces are sewn together, and passed in a spiral form up and down from end to end and back again, to go over the same course continuously throughout the entire time necessary for completing the operation. Another and more common method of arranging the pieces in the dye-vat is to pass two pieces, tied together end to end, over the winch between each separate pair of pegs, in which case the pieces revolve between the same pegs throughout the operation. Whichever method is followed, the operation and results are precisely the same. The required quantity of cold water is admitted into the trough, the pieces are arranged on the winch, the dye-stuff is introduced, and the machinery set in motion. Steam is then turned on, and the liquid is heated gently and gradually till it reaches about 180° Fahr. The process is continued for from an hour and a quarter to about two hours, during which time great care is taken to maintain the temperature arrived at, and to keep the pieces in constant circulation in and out of the vat. On the completion of the operation steam is shut off, and the pieces are rinsed through cold water, after which they are carefully and repeatedly washed. Fig. 6 presents a sectional view of an apparatus devised by Messrs Mather and Platt for loose washing after dyeing.

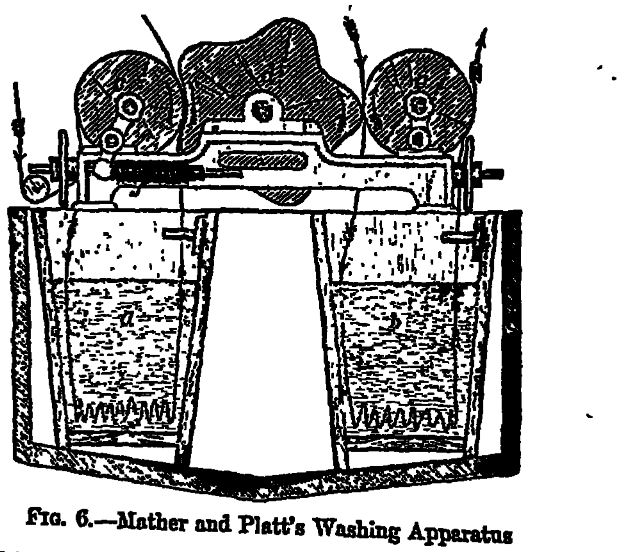

FIG. 6.—Mather and Platt's Washing Apparatus

In this machine there are two water-boxes *a*, *b*, and three bowls *c*, *d*, *e*, which are mounted horizontally in relation to each other. The central large bowl *d*, instead of being circular, has an irregular curved outline of alternate elevations and depressions. Against this irregular-shaped bowl the two side bowls *c* and *e* are made to press, and they move back and forward, following the irregular outline, pressed by powerful springs *f* acting on the axes on which they are mounted. They have thus a rubbing action in addition to their motion of revolution, an arrangement which produces a kind of flapping and squeezing action analagous to hand-washing.

Clearing.—At this point the dyed calicoes present a very unpromising appearance, the mordanted portions which have absorbed the dye being dull and heavy in colour, while the whites have a sickly pink aspect. The operations of clearing are necessary to remove all the dye-stuff which is loosely attached to the whites, and to develop and brighten the tints of dyed pattern. A variety of processes are pursued to accomplish this object, but in all the action of soap and some "chemick" or chlorine solution plays the principal part. The soap used must be free from all excess of alkali, and besides its detergent action it is supposed to be decomposed and give up part of its fatty acid to the lake formed by the mordant and the dye-stuff. The processes for clearing such calicoes as here described are as follows. After washing out of the dye-beck the goods are passed into a soaping beck, very similar in construction to the dye-beck, but surmounted with a pair of squeezing rollers instead of the winch of the dyeing apparatus. In this they are treated with a hot solution of soap; they are then washed out, squeezed, and again soaped,—the second time at a higher temperature than the first. After another washing they are "chemicked" in a weak chlorine solution, prepared by mixing chloride of lime with soda ash, with excess of soda, and from that a final washing in pure water should leave the goods clear and bright, ready for the finishing operations they receive in common with all other styles.

The reds and pinks produced by an alumina mordant with madder or artificial alizarin receive a different treatment. Mr Charles Dreyfus of Manchester, in a paper of great practical value communicated to the Society for the Promotion of Scientific Industry,[1] says of these colours: "They were some time ago dried and steamed; by the steaming a further quantity of colouring matter was combined to the mordant, and the shades thus obtained were fuller than if the goods had not been steamed. Now, instead of steaming only, the goods are passed through preparations the basis of which are fatty acids or fatty or resinous compounds; they are steamed after this preparation. I can speak highly of the good results obtained with some of these preparations, both as regards shade and saving of colour. The only difficulty is to obtain a good white; this can be overcome by careful and proper treatment of the goods. For reds and pinks there is a special and extra operation, commonly called the 'cutting.' It consists in passing the goods soaped and well washed through diluted nitromuriate of tin; the reds and pinks seem to be destroyed, becoming of a deep orange, but the subsequent soaping brings out again the brilliancy of the shade."

The processes above described are followed, with only modifications as to strength of mordants and the clearing operations, for the printing of calicoes with the madder preparations,—garancin, garanceux, and alizarin. The colours produced by these substances are as brilliant as madder colours, but they do not possess such fastness. On the other hand, the whites are not deeply stained in the dye-beck, and they generally require only a simple padding through a weak chlorine solution, and washing to clear the whites and prepare the goods for finishing. Some garancin and alizarin shades stand soaping well, and are improved in tone by such a treatment. Artificial alizarin and madder extract are now however chiefly used as steam colours, and to such perfection has printing in that style attained that the dye-house has been abandoned altogether in certain Continental establishments. The retention of dye-colour printing may now indeed be looked on as a question of comparative expense, which is determined chiefly by the price of fuel.

Turkey Red.—The production of this beautiful colour belongs rather to the province of Dyeing than to calico-printing; but as patterns are produced on it by means of discharges, it is necessary to include a notice of it under the head of dye colours. It is obtained with madder,

[1] Journal of the Society, vol. i. No. 3, Dec. 1874.

garancin, and both natural and artificial alizarin, but the pieces previously to being dyed have to undergo a long series of operations, which consist in passing them successively in olive oil and carbonate of soda, and hanging them in the air between the processes. They are then passed into a weak solution of red mordant, and afterwards of gall-nuts or sumach, well washed, and dyed in madder. When this has been effected, the colours are brightened by being boiled under pressure in a solution of soap and chloride of tin. On cloth so prepared certain discharge mixtures, principally tartaric acid properly thickened, are printed, and the pieces are passed through a solution of chloride of lime which removes the red, leaving a white pattern on a red ground. If a mineral colour or mordant is printed with the discharge it is left on the cloth in place of the discharged Turkey red, and thus various shades are produced in the brilliant red ground In bandanna printing the Turkey red calico is folded between metallic plates, which are perforated with designs, and so arranged that each figure of the design corresponds through the pile of prints so folded. The whole is then submitted to pressure, and a chlorine liquor is forced by pressure to percolate through the mass, which destroys the red colour in all those parts where the perforated plates allow the bleaching liquor to circulate.

Although madder and its various derivatives are the principal dye colours, there are various others which may be and sometimes are so treated. Of these the most important is logwood, the wood of *Hæmatoxylon campechianum*, which, although chiefly used as an oxidation colour, also yields with alumina and iron mordants black and sombre slate tints, which, however, do not possess the peculiar fastness of madders. Sapanwood and peachwood are also used as dye colours, the mordant and method of dyeing being the same as for madder or garancin; the cloth, however, does not receive the same treatment after dyeing, and does not require it, because these colours are much more easily removed from the parts of the cloth which are destitute of mordant. Beautiful reds and pinks are produced by means of cochineal; but this dye-stuff is chiefly used as a steam colour and for mousselines de laine. The mordant in the case of calicoes is either alumina or oxides of tin, and the method of proceeding is similar to that already described for madder and garancin colours. Quercitron bark (*Quercus tinctoria*), and flavin—a preparation from it, fustic, the wood of *Maclura tinctoria*, and Persian berries, the fruit of *Rhamnus infectorius*, are all used as dye colours, chiefly for the production of various shades of yellow In the paper above quoted, Mr C. Dreyfus states that mahogany has lately been brought out as a colour-giving substance, that it gives with the tin and alumina mordants very bright and fast shades of brown, much more brilliant than those made from catechu, and that he has dyed some very good specimens with Spanish mahogany.

Oxidation Colours.

Under this head is included a class of tinctorial substances which attach themselves to cotton fibre without the intervention of any mordant, but which for the development and fixation of their colour must undergo a process of oxidation after printing in the machine. The oxidation may be induced either by exposure of the pieces to atmospheric influences, by passing them through a solution containing an oxidizing agent, or by printing with the material some chemical substance which on exposure to heat gives off oxygen. The materials principally treated in this manner are indigo, catechu, aniline black, and certain blacks obtained from logwood. The processes adopted for the printing of indigo and aniline black—the two most important styles under this head—will make the practical application of the oxidation principle clear.

Indigotin, the colouring principle of indigo, is a substance obtainable from several other plants besides the species of *Indigofera*, from which it is commercially prepared. It is a body altogether insoluble in water, alcohol, ether, oils, or dilute acids or alkalies; but in presence of a variety of substances it takes up an additional equivalent of hydrogen, and thus is converted into white indigo, a colourless substance soluble in solutions of alkalies and alkaline earths. The change is thus represented.

$$\underset{\text{Indigotin}}{2(C_8H_5NO)} + \underset{\text{Hydrogen}}{2H} = \underset{\text{White Indigo}}{C_{16}H_{12}N_2O_2}.$$

White indigo is a most unstable compound, taking up oxygen with great facility either from the air or from certain solutions, and thus becoming retransformed into blue indigo. Advantage is taken of these circumstances in printing indigo colours; the colour is hydrogenized and dissolved, in which condition it is applied to calico, and on exposure of the pieces so dyed to the influence of oxygen the blue colour is both developed and fixed in the fibre. The following are the principal styles in practice:—

Indigo-blue dips.—This fine blue colour is produced in the old copperas vat method by putting in a vat holding 2000 gals. of water 60 ℔ of finely ground indigo, to which is gradually added 120 ℔ of green copperas, or sulphate of protoxide of iron, together with 180 ℔ of slaked lime. Owing to the lime removing the sulphuric acid from the salt of iron, the protoxide of that metal is liberated, and by its affinity for oxygen it decomposes the water, liberating hydrogen, which in its nascent condition reacts on the blue indigo, and thus transforms it into white indigo, which is soluble in the excess of lime employed in the operation. A zinc vat of recent introduction is now much more generally adopted than the above, its advantages being that the indigo is much more quickly converted, and by avoiding the abundant precipitate of sulphate of lime a better class of work is produced. The zinc vat is prepared by adding to the 2000 gals. of water 20 ℔ of ground indigo, 30 ℔ of iron filings, 30 ℔ of finely powdered zinc, and 35 ℔ of lime. The powdered zinc in presence of the lime decomposes the water, giving off hydrogen, which is taken up by the indigo, which then as white indigo dissolves in the lime.

By whichever process prepared, the dye-vat being ready, a piece of calico is hooked on a wooden frame and well stretched out; it is then dipped into the vat for fifteen minutes, taken out, and left exposed to the air for five minutes. The piece of calico, which is white when it comes out of the vat, gradually becomes green and then blue, owing to the oxygen of the air oxidizing the white indigo, and transforming it into blue, which is insoluble in water and fixed on the calico. The number of successive dips that the piece undergoes varies according to the various shades of blue which the printer requires. The pieces, after having been passed into a weak solution of sulphuric acid or "sours," which fixes the indigo thoroughly, only require to be well washed and dried.

To produce the well-known style of print which consists in a blue ground and white design, it is necessary to print a resist, pass the pieces into a vat containing lime, and then dye them in the above indigo vat. The principal resist used is the *blue resist*, a mixture of sulphate, acetate, and sometimes nitrate of copper, and the solution is thickened with British gum, or calcined flummery, together with pipe-clay for the block, and flour for the machine printing. When the cloth on which this paste has been printed is dipped into an indigo vat, the indigo is oxidized before it reaches the surface of the cloth. After

dyeing, the pieces are passed through weak sulphuric acid, not only to remove the oxide of copper, which has been precipitated, but also to fix the indigo on the calico, by liberating it entirely from its lime combination. Various other resist pastes are employed when it is desired to print other colours over the white portions, as for example, when orange or yellow grounds are desired the mixture consists of a salt of copper to resist the blue indigo vat, with a salt of lead to produce the chromate of lead by treatment with bichromate of potash after the blue dyeing is complete. The late J. Lightfoot of Accrington devised and patented, in 1867, a method of printing reduced indigo simultaneously with the mordants for madder, garancin, and other dye colours, by which a combination of indigo blue with other tints can be obtained of perfect clearness and brilliancy, without resorting to the complex and tedious processes involved in discharging colours, repeated printings, &c., when colours are blocked on a blue ground. The success of his process depends on the preparation of a pulp of indigotin and tin, in which he carefully avoided any excess of tin salt, so that it does not attract the alizarin in the madder beck, and in consequence leaves the indigo effects clear and unclouded.

China Blue.—This style of print is obtained by printing on the calico a mixture composed of pulverized indigo and sulphate of protoxide of iron, to which is sometimes added orpiment, and thickened with British gum. The pieces so printed are passed alternately, by means of rollers, first into a milk of lime, and then into a solution of sulphate of protoxide of iron, when there ensues one of the most interesting phenomena of calico-printing; for as fast as the blue indigo is reduced into white indigo, instead of being dissolved by the lime of the bath, it is retained with force through the molecular attraction of the fibre of the calico, and prevented leaving the cloth until it is fixed by the exposure of the piece to the oxygen of the atmosphere. The pieces then only require to be passed into weak sulphuric acid, washed, and dried, in order to be completed. This process is not now much used.

Pencil Blue is obtained by reducing blue into white indigo, by boiling it for several hours with protochloride of tin and alkali. When the indigo is well reduced, citrate of soda and starch are added; and after the whole is carried to the boiling-point, the calico is printed with it, passed into a milk of lime, washed, and dried.

Aniline Black is a most beautiful and fast colour, prepared by mixing a salt of aniline with a metallic salt and an oxidizing agent, which substances on exposure gradually react on each other, and develop a rich velvety black. There is thus produced one of the most unalterable colours known, resisting soap, acids, and even chlorine to a remarkable extent. It is a colour of recent introduction, having been first printed by Mr John Lightfoot of Accrington, in 1859, and patented in 1863; but it is now in very extensive use, many different methods for producing it having been devised and patented. The most extensively employed system is that patented in 1871 by Mr Lightfoot, the originator of the colour, which is thus given by Mr Dreyfus—30 pints chlorate of ammonia, prepared either by means of tartaric acid and chlorate of potash, or by another process without tartaric acid, are thickened with 6 to 8 ℔ wheat starch and 6 to 8 ℔ best dark British gum. When this colour has been well boiled, it is allowed to get cool, and then 7 pints of a solution of the purest and most neutral aniline salt that it is possible to get are added; this solution is made with 8 ℔ of salt to the gallon of water, with three-quarters to one pint of sulphide of copper paste. After the mixture is printed, the pieces are lightly dried and hung in the ageing room in a moist warm atmosphere, with the dry bulb thermometer about 80° and the wet bulb 10° lower. From thirty hours to two days are required to develop the colour, the printer judging of the progress of the ageing by the tint. According to Mr William Mather an ordinary ageing machine will effectually "age" the aniline black, if only a proper current of air is maintained of the requisite moisture and temperature. This is readily accomplished by having a properly contrived outlet to the chamber at the top, the draught of which is controllable, and inlets for fresh air in the sides of the chamber. This mode Mr Mather states is in successful operation, and by simple mechanical contrivances may be universally adopted. When the pattern has assumed a deep bottle-green tint, the goods are removed and passed through a solution either of bichromate of potash, of carbonate of soda, or of both mixed, and then soaped and dried. When aniline blacks are to be further printed with steam colours or dye colours, as is commonly the case, the treatment of the pieces after ageing is modified according to the necessities of the case.

Chrome Black is an oxidation colour produced by printing with logwood liquor and passing the goods through a bath of bichromate of potash, when the colouring principle of the logwood—hæmatoxylin—undergoes a special oxidation. The colours obtained from catechu are also fixed by oxidation, the colouring principle—catechuin—being only soluble in its unoxidized condition, and when oxidized after printing, it yields various browns and drabs, which have a very high degree of fastness.

Steam Colours.

The various processes of printing included under this head are of modern introduction, but they have steadily risen in importance, till now they embrace the largest part of the art, having so largely and rapidly superseded all other styles that the process would appear to be destined to become the predominant style of the future. Indeed, to such perfection have steam colours been brought that in some Continental establishments, it appears, the dye-house has been altogether closed and steam colours only now printed. As compared with the printing of dye colours the "topical" or steam colour style is simple, direct, and expeditious, requiring no tedious dyeing, and only light soaping, clearing, and finishing operations. By the dyeing processes alone the range of shades which it is practicable to print on one piece is strictly limited by what the mordants and their various combinations will yield with the particular dye-stuff used. But in steam colours there is no limit to the number and variety of shades which may be produced, each colour-box on the cylinder printing-machine containing the whole ingredients essential to the production and fixation of a separate and distinct shade or colour. In addition to this the steaming process can be and is extensively employed to supplement the effect of madder-printed or Turkey red goods by printing steam colours into the whites, produced either by resist pastes or by discharges printed on the dyed texture.

The distinguishing peculiarities of steam colours consist—1st, in printing direct and at one operation on the cloth the whole of the materials of the dye and its fixing agent properly mixed and thickened; and 2d, in submitting the printed cloth to the influence of steam, which effects the fixation of the colour. The effect produced by the combined heat and moisture of the steaming process is, in the case of certain combinations, purely mechanical, while in others a chemical reaction ensues. In the printing of what are termed pigment colours, or, in other words, insoluble coloured powders such as used by painters, they are simply mechanically fastened or glued to the cloth by means of albumen, or some body of similar constitution, which coagulates and becomes insoluble on the application of a

certain heat. In the case of the regular steam colours and aniline dyes there is printed on the cloth a chemical mixture or solution, which on the application of heat produces a reaction resulting in the precipitation of an insoluble compound in the fibres, or a volatilization of the solvent medium is caused, so that in both cases the same result—an insoluble precipitate—is produced.

With the development of steam colours efforts have been made with success to improve on the original crude and unsatisfactory manner in which the steaming was performed. The old method, still largely employed, consists in wrapping the printed cloth around a perforated cylinder of copper, called a "column," into one end of which a pipe passes for the admission of steam. Around the column are first wrapped several folds of felt, above which comes white calico, next the printed goods, and lastly an outer envelope of white calico. When so prepared the column is set perpendicularly on a steam pipe, a stop cock is opened, and steam is admitted into the interior of the column, which presses through and acts on the printed goods. Immediately on the conclusion of the process the column must be dismounted and the goods run off, otherwise steam might condense in the cloth and cause certain colours to run.

The most common arrangement for steaming, however, consists of the chest or "cottage," which is a cylindrical steam-tight chamber, into which a carriage is introduced. The carriage is mounted with a series of rollers on which the pieces to be steamed are hung, or, in a different arrangement, the cloth is fastened on a range of hooks projecting from a steam pipe. In the latter arrangement the hooks are heated by steam before the carriage is thrust into the chest, to prevent condensation of steam on the cold spikes, and consequent rust-staining of the cloth. Fig. 7 shows a

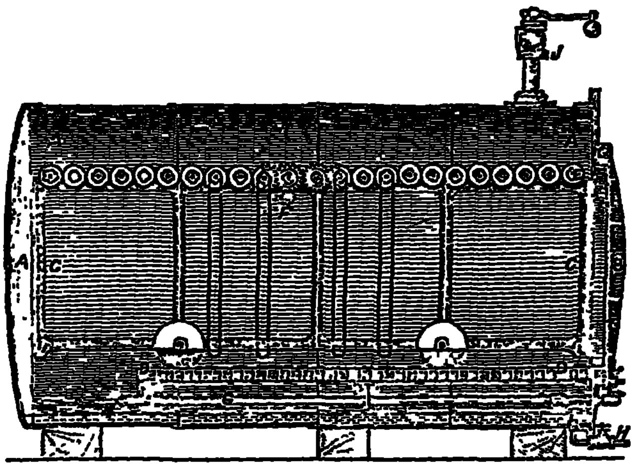

Fig. 7.—Section of Steaming Chest.

sectional view of an ordinary steaming chest by Messrs Mather and Platt. A represents the body of the chest; B the steam-tight door, which draws up when the chamber is to be opened; C the carriage or waggon fitted with a range of square wooden rollers E. The rollers are all geared to move by means of a cog-wheel F, which is turned by the attendant outside the chamber. The carriage is run in upon the rails D; steam is admitted by the perforated steam-pipe G; H is a tap for running off condensed water, and J is a safety-valve. While one carriage is in the chamber another is being filled and prepared outside to take its place when the goods are sufficiently steamed.

The steaming chest is at best only a crude and disconnected manner of performing one process in printing, and as all the others are continuous, it forms an awkward break in the series. To obviate this, and to secure expedition and continuity, a method of steaming has been devised by M. Cordillot of Moscow and Mr William Mather of Salford, which they patented in 1874. Their apparatus, of which a sectional illustration is shown in fig. 8, they claim will effectually steam 1000 pieces of 25 yards per

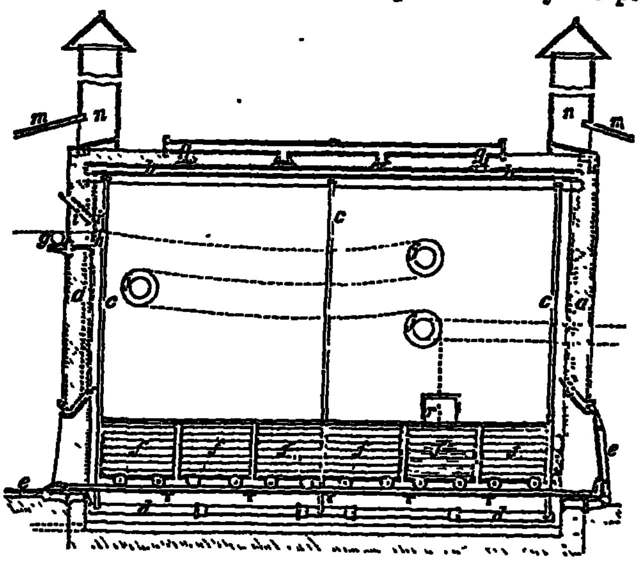

Fig. 8.—Cordillot and Mather's Steaming Apparatus.

day. According to their specification, it consists of "a brick or other chamber *a*, the roof of which is lined with a curved steam jacket *b*, connected by side pipes *c c* to the perforated pipe *d* near the floor. At each end of the chamber *a* is an opening closed by a steam-tight door *e*, through which openings the waggons for receiving the steamed fabrics are admitted and discharged. The fabric is fed into the chamber *a* over the feed roller *g* and between the small guide roller or tube *h* and copper troughs *i* and *i*, both of which and the tube *h* are heated by steam and project on each side of the wall to collect any moisture that may run down. When the fabric is in the chamber it is carried around three or other convenient number of rollers marked *j*, the last of which delivers it into one of the waggons *f*." The rollers are all heated by steam to prevent condensation, and as very moist steam is required for some colours, the supply pipe passes through water before entering through the pipes *q* into the curved jacket *b*, and thence going by the side pipes *c c* into the perforated pipe *d* as before described. "When the apparatus is in operation the steamed fabrics are deposited in one of the waggons, as shown in the figure, and when one is full both end doors are opened to allow the last waggon near the left-hand door to be discharged and to move the full waggon one step towards the exit door by the introduction of an empty waggon through the right-hand door; this brings another waggon in position for receiving the steamed fabrics, and while this is being filled the full waggon (after the four empty ones introduced to fill up the chamber at starting have passed through) that had been discharged can be emptied and brought back to the entrance door." The waggons are made of strong wire and are heated up before entering the chamber. By this system the patentees affirm that the goods are long enough exposed to the steam to allow the chemical reactions to take place in the cloth, so that the colours neither print off nor run during the remainder of the process, and the fixation is completed while the goods lie in the waggons inside the chamber. This system of steaming is in successful operation in some Manchester print-works.

Steam colours include two distinct classes of work—1st, pigment colours, or the series fixed by a mechanical effect produced in steaming; and 2d, ordinary steam colours, in which the fixation is effected more by chemical agency.

Pigment Colours are so named because the tinctorial agents employed are coloured lakes, and the insoluble mineral powders used otherwise as painters' colours. Only a limited number of painters' colours are so used, as, for a variety of reasons, many of them are not suitable for calico-printing. Colours containing arsenic, for example, and some others which produce brilliant effects, cannot be used on account of their highly poisonous nature. Others are excluded on account of their cost, some are too dull and muddy in colour, and some are liable to tarnish or darken on exposure to light, air, moisture, or other influences. The pigments which are most extensively useful are ultramarine blue, Guignet's or chrome green, and chrome orange, all of which are very largely used by themselves or in combination with other colours. Lamp black is also employed for the production of a solid grey, and vermilion-red with some other metallic sulphides are sometimes, though rarely, printed as pigment colours. The principal lakes used are carmine, corallin lake (a derivative of phenol or carbolic acid), black logwood lake, and several others prepared from the dye-woods with tin and alumina salts. The aniline dyes on their first introduction were also worked as pigment colours, and printed with albumen.

The first medium employed for fixing mineral pigments and lakes to calico was a solution of India rubber in coal naphtha, an agent which, so far as clearness and permanency of the printed colour is concerned, was perfectly satisfactory. The steaming dissipated the highly volatile naphtha and left the thin film of caoutchouc mixed with the colour firmly adherent to the tissue. But the inflammability of the copious naphtha fumes evolved gave rise to many serious accidents, and the method had on that account to be abandoned. No other medium has been found to give so satisfactory results as the protein compounds, of which albumen obtained from the white of eggs is the type. Besides egg albumen, blood albumen, lactarin or casein from milk, and gluten from wheaten flour are used as agents for fixing pigments. In printing with albumen advantage is taken of its well-known peculiarity of coagulating and becoming quite insoluble at a temperature under the boiling point. It is mixed with the colour and deposited on the cloth in its soluble state, when, by the operation of steaming, it coagulates and remains firmly attached to the tissue, imprisoning with it the particles of colour with which it was mixed. The cloth is not in reality dyed, but has only a coloured pattern mechanically fastened or glued to it. Egg albumen gives the most delicate and clear shades, but recent improvements in the preparation of blood albumen render it increasingly available for bright colours. Lactarin and gluten, dissolved by means of caustic alkalies, are used for printing ultramarine and other pigment colours. The length of time that pigment colours are left in the steaming apparatus varies from half-an-hour to an hour.

Ordinary Steam Colours.—The essential features of this style consist in printing direct on the cloth the dyeing material, mixed in proper proportion, with any necessary mordant, and certain acids or salts to keep the mixture in solution. On the application of moist heat after printing, the acid is evaporated or a chemical decomposition takes place in the case of the salt, and an insoluble precipitate is produced in the fibre. Steam colours possess great brilliancy, but they have not the fastness and solidity of madder-dyed goods. The dyes in the case of steam colours must be in the form of decoctions or prepared extracts of the special chemical tinctorial principles. Such preparations have of recent years come into very wide use, and with the progress of chemical science they are daily attaining greater prominence and perfection, so that the older application of crude materials is rapidly being supplanted by the use of agents of known strength and quality. Thus, as already mentioned, madder extract and artificial alizarin, treated as steam or "topical" colours, have largely taken the place of madder root as a dye colour, and by the preparation of artificial alizarin from anthracene, printers are now rendered independent of the vegetable kingdom as a source of their hitherto most important dye-stuff.

As a preparatory to printing, the cloth is mordanted or prepared by passing it through a solution of stannate of soda, and treating with a very weak solution of sulphuric acid which decomposes the stannate, combining with the soda, and leaves the stannic acid (peroxide of tin) precipitated in the fibres. Cloth thus prepared has much purer and brighter shades than simple bleached calico. The common steam colours include black and chocolate from logwood liquor, orange from annatto, yellow from Persian berry liquor and from bark liquor, green from Persian berries and yellow prussiate of potash, purple from logwood and red prussiate of potash, dark red from sapanwood and bark liquor, reds, purples, and chocolate from madder extract and alizarin, and blues from Prussian blue. Iron, alumina, and other mordants are used with these colours according to their character and the nature of the shades desired. The solvent principally employed is acetic acid, which readily volatilizes in the steaming process, but oxalic acid is also employed to keep certain special oxides in solution during the printing. Oxidizing agents, as the chlorate or bichromate of potash, are also required for the development of some colours. Steam blue is printed, not by using the Prussian blue colours ready formed, but by effecting the chemical reaction on the cloth itself, which results in the blue colour. In some cases yellow prussiate of potash is used, which yields Prussian blue; again, when the red prussiate is employed, Turnbull blue is the result; but a mixture of both, to which a proportion of ferro-prussiate of tin, called tin pulp, is added, is the source of the best steam blue. The reaction by which the colour is developed will be understood by instancing the development of Prussian blue from the yellow prussiate. It is mixed with an acid—tartaric, oxalic, or sulphuric—or the whole three combined, and printed on the cloth. In the steaming the added acid combines with the potassium of the prussiate and liberates ferrocyanic acid, which is further decomposed into cyanide of iron, abundant fumes of hydrocyanic acid (prussic acid) being meantime evolved. On withdrawing the goods from the steaming chest after this decomposition is complete the pieces are quite colourless, but exposure to the atmosphere in an ageing chamber, or passing them through an oxidizing solution, such as the bichromate of potash, develops the characteristic blue of Prussian blue.

Aniline Colours.—These colours now constitute the largest and most important section of steam-fixed dyeing materials, and in their behaviour and method of printing they form a class by themselves. The range of aniline colours now embraces almost every possible shade; and in no other department of scientific and technical research has equal activity been displayed within the few years which have passed since these colours were introduced; and the rewards of investigation have been commensurate. The number of colours introduced, and the methods of preparing them which have been suggested are beyond computation, and the list of those which are now in current use is exceedingly extensive. In addition to the dyes procured from aniline many more of an allied nature are prepared from other derivatives of coal-tar, phenol, naphthalin, and anthracene, some of which have also come into extensive use, and the applicability of others has been demonstrated. The topical use of these colours in connection with extract of madder, Guignet's green, ultramarine, &c., has exercised a powerful influence in improving the art of design in con-

nection with calico-printing, placing as they do at the disposal of the designer an unlimited range of the most striking, brilliant, and pure colours.

Aniline colours have a powerful affinity for animal substances, dyeing silk and woollen tissues readily without the intervention of any mordant. Taking advantage of this property aniline colours were, on their introduction, printed as dye colours, albumen being used as a mordant. An albuminous solution was printed and fixed on the cotton, and on its introduction, so prepared, into the dye-vat the albumen readily took up the colour, while the unmordanted portions merely imbibed an easily discharged stain. Aniline colours were also printed with albumen in the manner already described as applied to pigments and coloured lakes; and the patents secured by Mr Walter Crum, in 1859, for the application of gluten and lactarin in printing, had reference chiefly to the use of aniline colours. The process of fixing these colours now generally adopted is known as the arsenite of alumina process. In this process the dye is dissolved in water or acetic acid, carefully filtered through a fine cloth and mixed with acetate of alumina, a thickener, and arsenious acid dissolved in glycerine. This mixture is printed on the cloth, which is then introduced into the steaming chest. In the steaming, acetic acid is liberated and arsenite of alumina formed, which with the aniline colour is precipitated in the fibres as a brilliant insoluble lake.

Spirit Colours.

This style of printing consists simply of a modification of the process for ordinary steam colours, but excluding the steaming. All the decoctions and extracts used for regular steam colours may be employed in this method, but they are mixed with such large proportions of the mordants and acids that were they submitted to the action of steam the fibre would be quite destroyed. When printed, spirit colours are therefore simply dried and aged for several hours, after which they are rinsed in water, washed, and dried. The style yields very brilliant but very loose and fugitive colours, and is now falling into disrepute.

Finishing Processes.

After the prints have undergone the various operations described above, they are submitted to a series of processes, whose object is to give to the fabrics such an appearance as will please the eye of the buyer. All the finishing processes have one common end, namely, to fill up the interstices which exist in the fabrics, and thus give to the calico a more substantial and glossy appearance; and this is effected by filling the cloth with boiled starch, farina, or sour flour, which is obtained from wheat flour which has been allowed to ferment. To these are ofter added large quantities of sulphate of lime or baryta, and other similar substances, with the object of imparting to the cloth a weight and appearance of solidity which it does not really possess. The finishing processes are varied according to the nature of the print, muslins requiring a quite distinct method of treatment from ordinary calicoes, and furniture chintzes also receive a finish peculiar to glazed goods. Some of the apparatus employed in finishing will be found figured under the heading Bleaching, where also the subject is entered into in some detail. As the general features of finishing, including water-mangling, drying, damping, starching, and calendering are the same both for white cottons and prints, it is unnecessary here to detail these operations. The machines and operations in a finishing-room may be briefly noticed as follows. The goods are opened by passing over a winch at a considerable elevation, and if necessary stretched in breadth on a machine which evens the texture and draws it out laterally. They are then passed into the chloring machine, which has two rollers, one of brass and one covered with india-rubber. The lower one is made to revolve in an aqueous solution of chlorine, and as the cloth passes between the rollers it is saturated with this solution. It passes immediately through a box containing a vapour of steam, which at once arrests the action of the chlorine, the momentary contact being considered sufficient to brighten the white ground without giving time for the colours to be affected. From the steaming box the piece passes through a water mangle, where pure water is spurted on the cloth, and after passing through the trough it receives a hard squeeze to extract as much moisture as possible before the drying is reached. The machine is a range of steam cans, generally made of copper. The next operation is that of starching, the machinery of which is almost identical with that used for chloring, starch paste, however, occupying the place of the chlorine liquor. The lower roller revolves in and carries up the starch to the cloth, which passes round the upper rollers and becomes saturated by the squeezing action produced and regulated by the screws and levers of the machine. After starching, the goods pass direct to another drying machine, whence they are taken to be damped by a slight sprinkling of water, which they receive in passing over a simple machine for the purpose, consisting of a rapidly revolving brush throwing up a fine spray. Calendering is the next and final operation, after which each piece is separated and folded up by a plaiting machine, or hooked by hand. It is then made up in the ordinary book form, and after being pressed in a screw or hydraulic press is ready for the market. (J. PA.)

CALICUT, or Kolikod, a seaport town of India on the western coast, in the British district of Malabar and the presidency of Madras, situated about 560 miles S. of Bombay, in 11 15′ N. lat. and 75° 52′ E. long. The town stands on the sea-shore in a low and unsheltered position; and as there is neither river nor harbour, ships are compelled to anchor in five or six fathoms water, about two or three miles from land The houses are for the most part built either of sun-dried brick or laterite, and have a tidy appearance. In the quarter of the Moplahs or Mapillas there are several mosques, and the Portuguese quarter possesses a Roman Catholic church One of the largest buildings is the jail, which can accommodate 600 prisoners. The port is frequented by vessels from the Red Sea and the Persian Gulf, which return with freights of rice, cocoanuts, ginger, cardamoms, sandal-wood, and teak. The weaving of cotton, for which the place was at one time so famous that its name became identified with its *calico*, is no longer of any importance. Calicut is of considerable antiquity; and about the 7th century it had its population largely increased by the immigration of the Moplahs, a fanatical race of Mahometans from Arabia, who entered enthusiastically into commercial life. It was the first place in India visited by any European navigator, for it was there that Vasco de Gama arrived in May 1498, ten months and two days after his departure from Lisbon. At that time it was a very flourishing city, and contained several stately buildings, among which was especially mentioned a Brahminical temple, not inferior to the largest monastery in Portugal. In 1509 the Marshal Don Fernando Continho made an unsuccessful attack on the city; and in the following year it was again assailed by Albuquerque with 3000 troops. On this occasion the palace was plundered and the town burnt; but the Portuguese were finally repulsed, and fled

to their ships after heavy loss. Not long after they concluded a peace with Prince Zamorin or Tamuri, and were allowed to build a fortified factory in the town. An English factory was founded in 1616. The town was taken in 1765 by Hyder Ali, who expelled all the merchants and factors, and destroyed the cocoa-nut trees, sandal-wood, and pepper vines, that the country, reduced to ruin, might present no temptation to the cupidity of Europeans. In 1782 the troops of Hyder were driven from Calicut by the British; but in 1789 it was taken and destroyed by his son Tippoo, who carried off the inhabitants to Beypore, and treated them with great cruelty. In the latter part of 1790 the country was occupied by the British; and under the treaty concluded in 1792, whereby Tippoo was deprived of half his dominions, Calicut fell to the British. After this event the inhabitants returned and rebuilt the town, which in 1800 consisted of 5000 houses. The present population is upwards of 25,000, composed largely of Moplahs, but including about 4000 or 5000 Portuguese, besides Parsees, English, &c.

CALIFORNIA

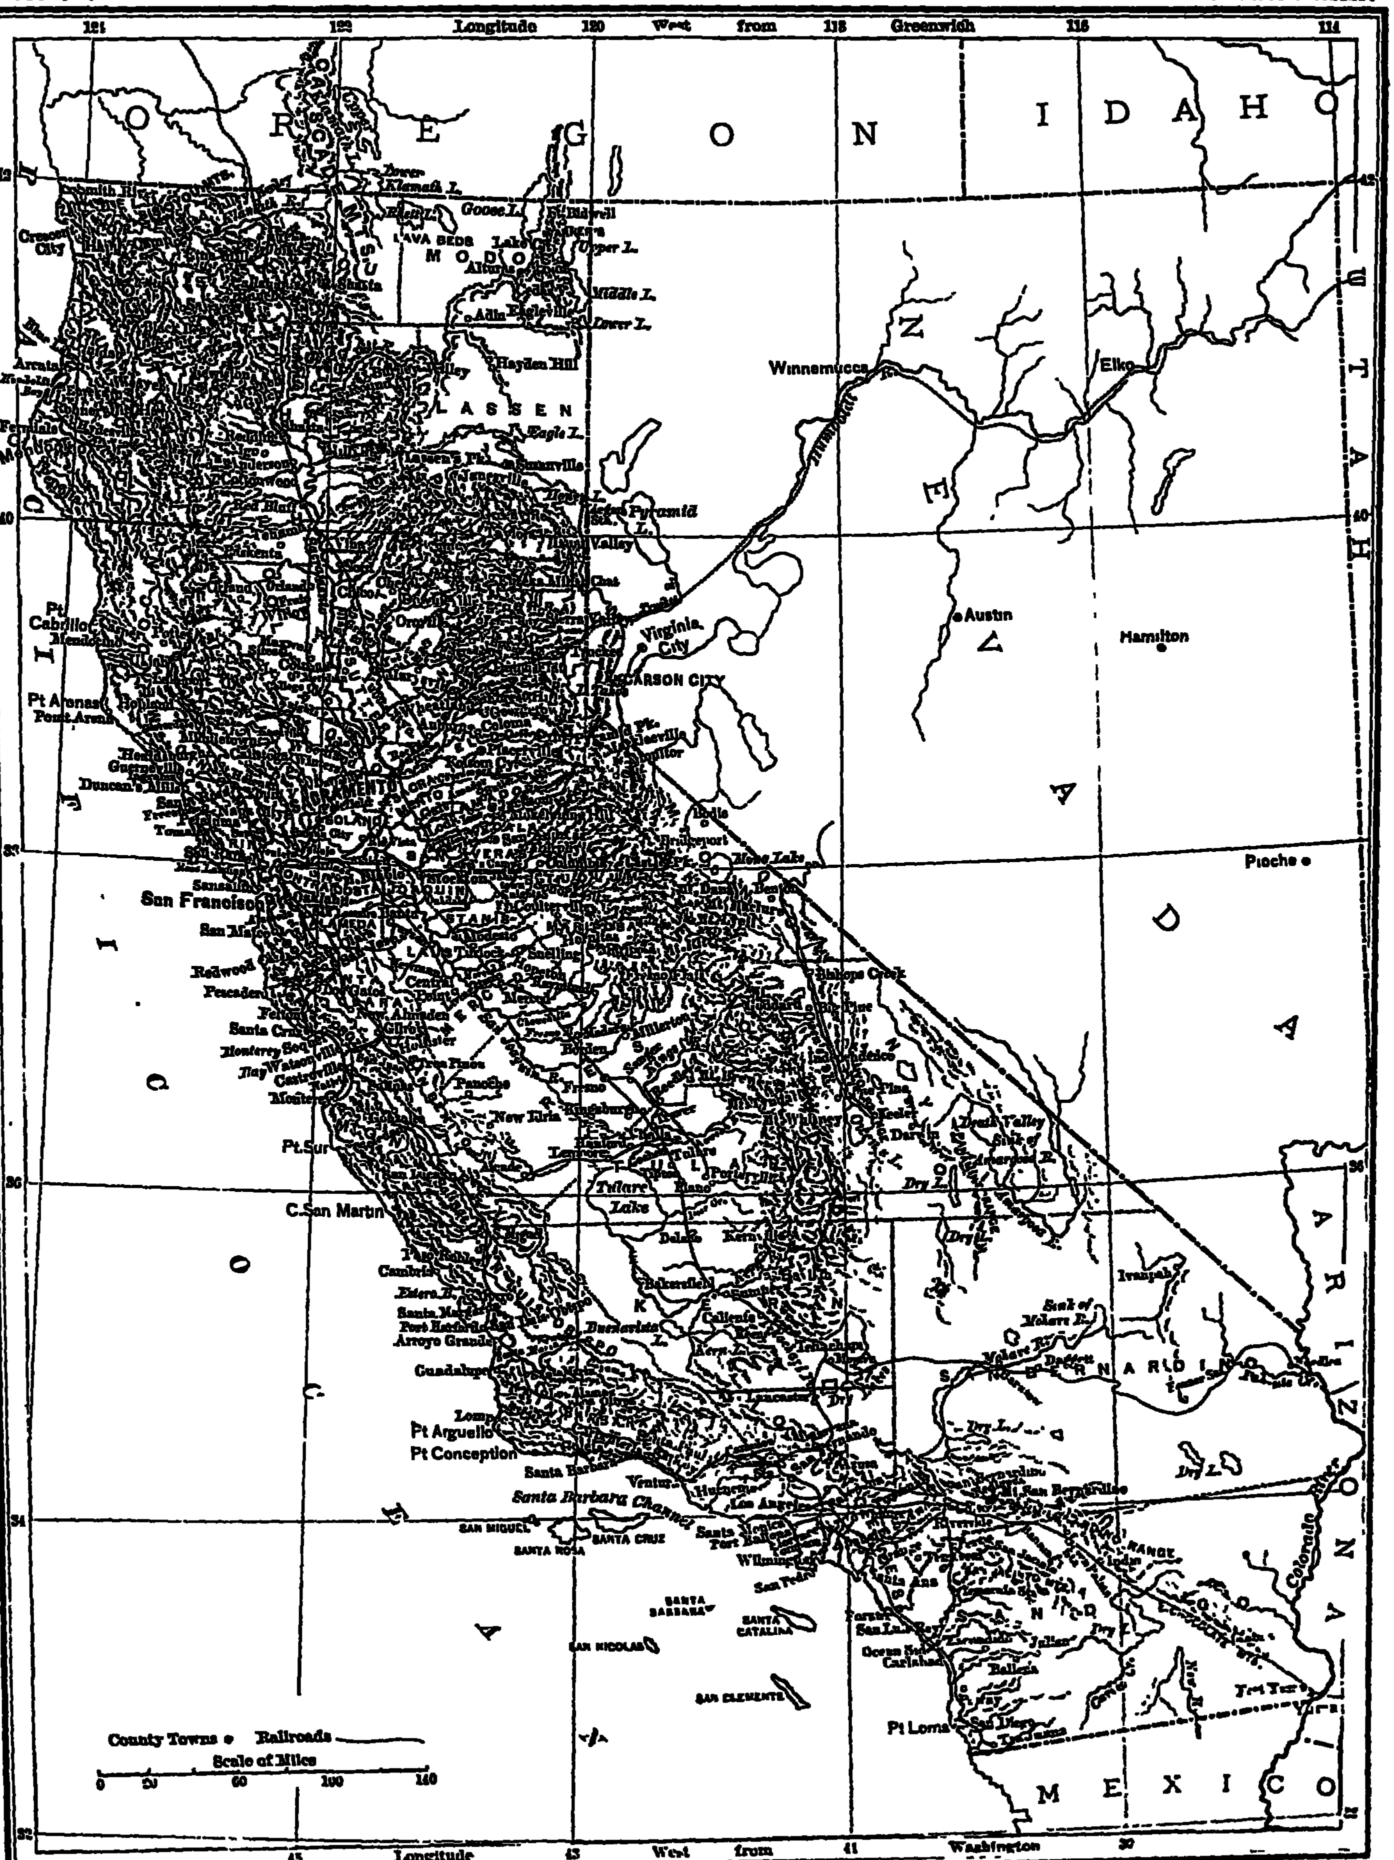
CALIFORNIA, the name originally given to a portion of the region of western North America bordering on the Pacific Ocean, and apparently taken from a Spanish romance (*Las Sergas de Esplandian*), in which the author speaks of "the great island of California, where a great abundance of gold and precious stones is found." This romance was published in 1510, and, becoming quite popular, the name of California probably struck the fancy of some one of the officers or companions of Cortez, and was applied by them to the newly-discovered country, perhaps on account of its association with a region fabulously rich in gold, the early Spanish discoverers in America always expecting to find an El Dorado in every new region they entered

As at first used, the name of California was applied to the coast and the territory at a little distance from it, north of Mexico; gradually it was extended over what we now call the "Great Basin," and with no well-defined limits to the north At the present time, the name California means only the State of California, one of the United States of America, and the peninsula is called Lower California. To the Spanish Americans these natural divisions of the country were and still are known as Upper and Lower California (Alta and Baja California), and the two were called "Las Californias"—the Californias.

The first discovery of the coast of Lower California was made in 1534, by an expedition sent out by Cortez, and consisting of two ships, commanded by Bezerra de Mendoza, and Hernando de Grijalva; and later, the gulf now known as the Gulf of California was discovered and navigated by Cortez himself; after whom it was for a time called El Mar de Cortez, and later El Mar Vermejo (the Red or Vermilion Sea), in consequence of the red colour which it has at times, and which is probably due to the multitudes of small animalculæ (crustaceans ?) inhabiting its waters. In 1540 the mouth of the Colorado River was discovered by Alarcon, in command of a fleet sent out by Mendoza for geographical exploration. In 1542 the coast of California proper was explored by Cabrillo as far north as Cape Mendocino, in latitude 40°30′. In 1578 Sir Francis Drake entered the Pacific, and coasted along the shores of the American continent, reaching a point as far north as 48°. Whether he discovered the bay and harbour of San Francisco has been and still is a matter of dispute. By some he is supposed to have tarried and refitted his ships at what is now known as Sir Francis Drake's Bay; by others he is believed to have done this in the Bay of San Francisco itself. The evidence seems to decidedly preponderate in favour of the first of these suppositions. In 1602 the bays of San Diego and Monterey were discovered by Viscaino; but more than a hundred and fifty years elapsed before the latter was visited again, and before settlements began to be made on the coast of Upper California. The peninsula (Lower California) was entered by Jesuit missionaries in 1697, and a permanent mission established at Loreto; where, and at other points, the Jesuits maintained themselves, on the whole successfully, until 1767, when they were expelled from the country by order of Charles III. of Spain, and all their property turned over to the Franciscan monks. Later, the Dominicans obtained exclusive possession of the peninsula; and the Franciscans, not unwillingly, withdrew to Upper California, where they established themselves, built numerous missions, and throve remarkably until Mexico became independent of Spain in 1822; this event was a death-blow to the establishments of the Franciscans, which from that time forward lost ground from year to year, and finally were broken up altogether in 1840. The treatment by the fathers of the natives of the country was successful so far as the accumulation of material wealth was concerned, but not in the slightest degree conducive to their intellectual advancement or development, as the so-called converts were simply the slaves of the "good fathers." The whole number of the mission establishments was twenty-one,—the first founded in 1769, the last in 1820. They were all on or near the coast or bay of San Francisco, and the fathers displayed most excellent judgment in selecting for their sites the very garden-spots of the country. The number of the aboriginal inhabitants of California has rapidly decreased within the past forty or fifty years. The various authorities agree in fixing their number at over 100,000 in 1823. In 1863, according to the census made by the Indian Department, there were only 29,000; the census of 1870 gave about the same results, namely, 29,025, 5784 being actually enumerated, and the remainder merely an estimate. It is certain that the decrease in the Indian population was at one time exceedingly rapid; it would appear, however, that at present it is much less so. The few that are left are mostly a degraded, miserable set of beings.

During the time of the flourishing of the missions of California, the connection of the country with Spain through Mexico was a very loose one. Gradually a trade of some importance sprang up between the Atlantic and Pacific sides of the continent. Boston had for a number of years an entire monopoly of this business, which consisted chiefly of an exchange of groceries and cotton goods for furs and hides. The voyage usually lasted two years or more, and the profits were large. A few Englishmen and Americans wandered into California from different parts of the world between 1810 and 1830; and some adventurous and daring men found their way across the continent, in the pursuit of the dangerous and exciting business of hunting and trapping. It is estimated that there were, in 1830, as many as 500 foreigners on the west side of the Sierra Nevada. Of all these early pioneers, John A. Sutter is the one who is best known, from the fact that the first effective discovery of gold, by the Americans, was made by men in his employ; and also on account of the generous hospitality with which he welcomed the first comers into California, notably Fremont and his party.

In 1842 Commodore Jones of the American navy captured the fort of Monterey, raised the stars and stripes, and took



ENCYCLOPÆDIA BRITANNICA NINTH EDITION

possession of the country for the United States; but the next day he hauled down his colours, and apologized for his mistake. About this time the attention of the United States Government began to be strongly attracted towards California; and, as is universally believed in that State, the French and the English were also looking in that direction, with a view to a future possible taking possession of the country All the circumstances connected with the seizing of California by the United States will probably never be known. It appears pretty clear, however, that the authorities at Washington, having determined on a war with Mexico, and fully aware of the importance to the United States of an extension of their territory on the Pacific, resolved to take possession of California, so that after the termination of the war, matters being settled on the basis of *uti possidetis*, that country would become a part of the United States. At all events, Fremont being accidentally engaged in conducting a scientific expedition on the Pacific coast, received in May 1846, verbal instructions from an officer dispatched from Washington in a national ship, and who had crossed from Vera Cruz to Mazatlan. In consequence of these instructions, he turned back, made his way at once to Sutter's Fort, then to Sonoma, where he organized a battalion of mounted riflemen; and on the 5th of July he called his forces together, and recommended a declaration of independence. On the 2d of the same month a United States frigate had arrived at Monterey, where, on the 7th, the commander hoisted the American flag, issuing at the same time a proclamation, in which California was declared to be, from that time forth, a portion of the United States. This was followed by some fighting with the native Californians, and much bitter discussion and dissension among the different officers of the navy and army, who were concerned in the conquest of the country. The principal result was, that Fremont, who was tried by court-martial, found guilty of mutiny, and sentenced to lose his commission, was ever afterwards considered by the people to have been the real conqueror of California; and, in consequence, he came near being elevated to the Presidency. The country was entirely pacified before June 1847; and in March 1848 a treaty was ratified between the Governments of the United States and Mexico, by which the whole of Upper California was ceded to the United States, just at the moment when the discovery of gold on the American River was beginning to attract attention; and when the news of the ratification reached the Pacific coast, the excitement had already spread far and wide; San Francisco was deserted, and the whole population of the country was at work in the mountains, digging gold. The discussion as to what should be done with California, when acquired, began in Congress in 1846; and the question of slavery or no slavery in the new territory was at once raised. A most furious conflict followed, and nothing was accomplished during that session or the next; even as late as the adjournment of Congress, on the 4th of March 1849, the only progress made towards creating a Government for the new territory, was that the United States revenue laws had been extended over it, and San Francisco made a port of entry. In consequence of this the people themselves got together in September 1849, and a constitution was framed forbidding slavery, and in other respects resembling the constitutions of the free American States On the 7th of September 1850, a bill finally passed Congress, admitting California into the Union as a State, and without slavery, but leaving New Mexico and Utah open to its introduction. At the same time the celebrated "Compromise Measures" became a law and these were supposed to have settled the question of slavery for ever in the republic; the lapse of a few years proved, however, that this was a problem which admitted of no peaceful solution. By the treaty with Mexico, the United States did not acquire the Peninsula of Lower California, although they had military possession of it at that time. It was probably known to the authorities at Washington that it was a region of little value, as compared with the country to the north of it, or California proper.

LOWER CALIFORNIA.—Under this designation is comprised the whole peninsula, and it extends from Cape St Lucas to the boundary between the United States and Mexico, which is a line "drawn from the middle of the Rio Gila, where it unites with the Colorado, to a point on the coast of the Pacific one marine league due south of the southernmost point of the port of San Diego." The breadth of the peninsula varies very much, it being from five to six times as great between the parallels of 27° and 28° as it is opposite the Bay of La Paz. The area of Lower California has been estimated as 58,000 square miles; the recent charts of the American Hydrographic Office, based on original surveys, make the peninsula narrower than it was formerly believed to be, and its area has not been computed since these surveys were made; it will probably not exceed 50,000 square miles.

The interior of Lower California is chiefly known to us, as to its physical and geological structure, from a reconnaissance made by Messrs Gabb and Loehr, of the State Geological Survey of California, in 1867. This exploration was set on foot in order that some information might be obtained relative to the value of a concession made by the Mexican Government to an American company This grant was expected to lead to a settlement of the country, but the whole thing turned out a failure.

According to Mr Gabb, the peninsula is divided into three distinct portions. The northern and southern extremities have much in common with each other, while the middle division differs decidedly from the others in its physical characters. The most southern division consists chiefly of granitic rocks and high ranges, which with their spurs cover nearly the whole area from Cape St Lucas to La Paz. Within this district, and lying between the spurs of the mountains, are many small valleys, some of which are very fertile, and well supplied with water. According to the American hydrographic charts, there are in this part of the peninsula two well-defined ranges, and the culminating point is given as 6300 feet in altitude. It is in this region, about half-way from Cape St Lucas to La Paz, that the principal mines of the peninsula are situated; and these are the only ones which, thus far, have proved to be of much value. They are in the districts of San Antonio and Triunfo. In 1867 these mines were producing at the rate of about $20,000 in value of silver per month; and, from recent newspaper notices, it would appear that they are still worked with success. The ores are, however, refractory, and not easily treated.

Proceeding northwardly into the middle section of the peninsula, the granitic masses unite and form one mountain range, which runs parallel with the coast of the gulf, and at a distance of fifteen or twenty miles from it. It is known as the Sierra Gigantea, or del Gigante, and has an elevation of from 3000 to 4000 feet. Crossing this range and descending its western slope, its inclination is found to be very gradual, the granitic mass being flanked on that side by heavy accumulations of sandstone, which has a gentle dip away from the crest of the ridge. This sandstone is quite destitute of fossils, but is believed by Mr Gabb to be of Miocene age. It is cut by numerous volcanic dykes, and also contains great quantities of material of eruptive origin.. in the form of interstratified masses. In this portion of the peninsula the settlements are confined to the eastern base of the Sierra Gigantea. Here, at numerous points along the coast, there are small valleys, with good harbours

adjacent; and these little patches of country are very fertile and adapted to the growth of tropical and semi-tropical plants. By far the greater portion of the region, however, is extremely barren and forbidding; although occasional deep ravines and narrow valleys offer a marked contrast to the general sterility of the rest of the country. The northern division of the peninsula is considerably broken by mountain ranges, resembling in this respect the southern extremity. The culminating point is put down on the American hydrographic charts at 9130 feet in altitude, and it is called Mount Calamahue. Between the ranges are broad valleys, covered with grass, and said to possess some agricultural value, although as yet almost entirely unoccupied.

The dryness of the climate is the characteristic feature of the peninsula of Lower California; and although there are no reliable statistics of the rainfall it is undoubtedly very small. It is, indeed, very irregular, there being long periods of absolute dryness, in certain regions at least. The yearly average fall over the whole peninsula, for a long period of years, would perhaps not exceed three or four inches. As in the drier portion of Upper California, so here, when the rain does fall, it occasionally comes down in almost destructive quantity, over a very limited area, in the form of what are popularly known as "cloud-bursts."

Owing to the dryness of the climate in part, and also to the character of the Mexican Government, all the numerous attempts which have been made to settle Lower California have proved failures. The population at present is estimated at from 8000 to 15,000, about two-thirds of whom live near the southern extremity of the peninsula. The harbours on both coasts are numerous, and that of Magdalena Bay is hardly inferior in extent and availability to the Bay of San Francisco itself. Whale-fishing on the west coast, and especially about Sebastian Viscaino Bay, was, a few years ago, carried on very extensively. In the winter of 1848 there were fifty American ships anchored in the bay and lagoons of Magdalena, chiefly engaged in capturing the "California Grey" whale (*Rhachianectes glaucus*, Cope). The pearl-fisheries of Lower California have also for many years been of some importance; they are conducted by companies, and the divers are chiefly Yaqui Indians. The total value of the pearls obtained, within the last century and a half, has been estimated at five or six millions of dollars; but this, of course, can hardly be considered as being anything more than a rough approximation. On the whole, the prospects of Lower California are not very cheering; dryness and sterility are the dominating features of a very large portion of the country. The emigration schemes have all failed, and not without considerable suffering to the unfortunate people who from time to time have been deluded into the belief that the peninsula was a rich and fertile region. The attempts at mining for copper, which have been made at various points north of Triunfo, have all proved unsuccessful.

THE STATE OF CALIFORNIA. *Area.*—This is what is now always meant when the word "California" alone is used. It is in part the equivalent of the "Upper California" (Alta California) of the Spanish,—the present state of Nevada, and also the territories of Arizona and Utah, as well as parts of Wyoming and New Mexico, having been also included under that somewhat vague designation. California extends from the boundary already defined on the south to the parallel of 42°, which is the dividing line between this State and Oregon. On the east, the 120th meridian forms the boundary from 42° south to the intersection of that meridian with the 39th parallel, which takes place within the waters of Lake Tahoe, near its southern end. From this point the boundary runs obliquely in a south-easterly direction to the intersection of the 35th parallel with the Colorado River, and thence down the river to the Mexican boundary line opposite the mouth of the Gila. The whole area thus embraced has been variously estimated at from 155,000 to 188,981 square miles. The last-mentioned figures are those given in the latest document published in connection with the United States census,—General Walker's *Statistical Atlas*,—as well as in the *Report* of the Commissioner of the United States General Land Office for 1866. It is believed, however, that the first-named figures are much nearer the truth than the other higher statement, and that the area of California is somewhere between 155,000 and 160,000 square miles.

Topography.—The surface and climate of California, although extremely varied in character, bear everywhere a peculiar impress, very different from that of the Atlantic coast and Mississippi Valley States. The division of the year into two seasons—the wet and the dry—marks this portion of the Pacific coast in the most decided manner, and this natural climatic area coincides almost exactly in its extension with that of the State of California itself. Soon after crossing the Oregon line, we enter a region of summer and winter rains; and, in Lower California, although the entire precipitation is exceedingly small, it is, on the whole, decidedly tropical in its character.

Before, however, the nature of the Californian climate can be understood, it will be necessary to give some account of the physical structure of the State, and to indicate the interesting and somewhat peculiar character of the relief of its surface. California may be divided into three quite distinct portions, and these are very different from each other in importance,—the central being much the most densely populated, and in every respect the most valuable. This central portion is embraced between the parallels of 35° and 40°, and has, on its eastern side, the Sierra Nevada, and on its western the Coast Ranges, with the Pacific Ocean at their western base. Between these two mountain chains lies the Great Central Valley, which forms so marked a feature in the topography of the state. This valley is drained by the Sacramento River, flowing from the north, and the San Joaquin from the south, the two uniting about midway between the northern and southern extremities of the valley, and entering the Bay of San Francisco through Suisun and San Pablo bays, which latter is, in fact, but the northern expansion of San Francisco Bay itself. Suisun Bay, on the other hand, is rather the partly submerged delta of the united rivers, being shallow, and containing large, low islands covered with a dense growth of "tule" (*Scirpus palustris*). The entire length of the Great Valley is about 450 miles; and its breadth, which is small in its northern part, and gradually increasing towards the south, averages about 40 miles, including the lower foot-hills, so that the entire almost level area contains about 18,000 square miles. The direction of the valley is parallel with that of the ranges between which it is enclosed, or about N. 31° W.; but it gradually takes a more northerly course to the north of the Bay of San Francisco, in harmony with the change in the trend of the coast beyond the parallel of 39°. From the mouth of the Sacramento to Redding, at the northern head of the valley, the rise is 556 feet in 192 miles; and from the mouth of the San Joaquin to Kern Lake it is 282 feet in 260 miles. A striking feature of the Sacramento River is the fact that for 200 miles north from the mouth of the Feather River it does not receive a single tributary of any note, although walled in by high mountain ranges. Indeed, the whole of the Great Valley is thus surrounded; the only break being at San Francisco, where the channel which connects it with the sea—

the Golden Gate—is only one mile wide in its narrowest part. The region thus enclosed, computing it from the divide, or water-shed, of the enclosing mountain ranges, is 520 miles in length, and it has an average breadth of 110 miles. This gives an approximate area of 57,200 square miles, as stated by U. S. Irrigation Commissioners, their estimates having been made on the basis of the State Geological Survey maps. The drainage of this entire area reaches the sea through the Golden Gate. But before noticing the lakes and rivers which belong to the Great Valley, it will be desirable to give some idea of the mountain ranges in which these rivers take their rise; and it should be added in justice, that nearly all that is known of the detailed structure and elevation of the mountain chains of California is due to the work of the Geological Survey.

The Sierra Nevada, or Snowy Range, of California is, on the whole, the largest and most interesting chain of mountains within the limits of the United States. Its scenery is attractive, and in some respects quite unique; its vegetation is unsurpassed in grandeur, unless it be by that of the Australian forests; its mining resources are large, and have been the direct cause of the rapid peopling of the Pacific side of the continent and of the building up of eleven States and Territories in what was before almost an unknown region. In general altitude, the Sierra Nevada does not much excel some of the ranges of the Rocky Mountains proper, although it has one summit higher than any yet ascertained to exist in the United States, not including, however, the Alaskan territory. The length of the chain, from Mount San Jacinto to Mount Shasta, is about 600 miles; but, on some accounts, it would be more proper to consider the Sierra as beginning at the Tahichipi Pass and terminating at Lassen's Peak, in which case its length would be about 430 miles. The breadth of this great mass of mountains varies from 75 to 100 miles; and it narrows towards the north, while its altitude also declines in the same direction. The slope of the range is everywhere long and gradual on the west, and short and precipitous to the east, in which latter direction, of course, the general level of the Great Basin is attained, and this is from 4000 to 5000 feet above the sea. The highest part of the range is between the parallels of 36° 30′ and 37° 30′; here the passes are about 12,000 feet in elevation above the sea-level, and the peaks range from 13,000 to 14,886 feet in altitude, the culminating point, Mount Whitney, being about 600 feet higher than any peak yet measured in the Rocky Mountains. From this peak, going north, the range declines gradually, and at the point where the Central Pacific Railroad crosses it the summit is only 7000 feet above the sea; this is in latitude 39° 20′. The slope of the Sierra in the central part of the State opposite Sacramento is about 100 feet to the mile, the range being there seventy miles in breadth between the valley and the crest; farther south, opposite Visalia, the average rise is as much as 240 feet to the mile, up to the summit of the passes, and 300 feet to the peaks. In this part of the range, the slope on the east is very abrupt, being as much as 1000 feet to the mile from the summit to the level of Owen's Valley, a descent of about 10,000 feet. The western side of the Sierra Nevada is furrowed by extremely deep and precipitous gorges, or cañons, as they are universally called in California. These are narrow at the bottom, where there is usually barely room for the river to run at an ordinary stage of water; their sides slope upwards at a very steep angle, often as much as 30°; and they are sunk from 1 to 3000 feet, or even more, below the general level. These cañons become more and more marked features of the range as we proceed north in the Sierra; and where the volcanic formations have spread themselves uniformly over the flanks of the mountains, so as to form a smooth and almost level surface, as is the case over an extensive area, the contrast between the deep and precipitous cañons and the plain-like region, with its gentle slope to the west, in which they have been excavated, is a very marked one.

The Coast Ranges form a large mass of mountains, almost as broad as the Sierra, but much inferior to it in elevation, and at the same time more complicated in details. The Sierra Nevada is essentially one range or chain, with great simplicity of structure. It is only here and there that, along the crest or near it, a double line of summits exists, with deep longitudinal valleys between, which are occasionally occupied by lakes, as in the case of Lake Tahoe; while the Coast Ranges, on the other hand, are made up of numerous broken and indistinct chains, each of which usually has a distinct name, the different groups of ranges having, however, on the whole a well-marked parallelism with the coast. Near the Bay of San Francisco the culminating summits are about 4000 feet in altitude; to the north and south of the bay the elevation of the ranges increases. Monte Diablo, twenty-eight miles distant from San Francisco in a north-north-easterly direction, is 3856 feet in height, and forms a well-known land-mark, being, from its somewhat isolated position on the north, a very conspicuous object over much of the central portion of the state. The view from its summit is remarkably comprehensive, as is that from Mount St Helena, at the head of Napa Valley, sixty miles north of San Francisco, and 4343 feet in height.

The flanks of the Coast Ranges on the western side of the Great Valley are very scantily provided with forests, and there is not a single stream on that side permanent enough to reach either the Sacramento or San Joaquin throughout the entire year. The only streams which carry water in summer on the west side of the Sacramento Valley are Puta, Cache, and Stoney creeks, and these all disappear during the dry season, soon after leaving the foot-hills. On the eastern side, however, *i.e.*, of the valley, the conditions are greatly changed. The rain-fall, almost entirely cut off on the eastern slope of the Coast Ranges, becomes considerable on the western side of the more elevated Sierra, and numerous large rivers are fed from the melting snow during the summer, although, towards the close of the dry season, the body of water which they carry has usually become very much diminished. The streams tributary to the Sacramento on the east side are—the Feather, Yuba, American, Consumnes, Mokelumne, and several other smaller ones. The Feather has the largest drainage area of any river having its source in the Sierra. It runs for a long distance parallel with the Sacramento, receiving on the east all the drainage which would otherwise run into that river. There are no lakes in the Sacramento division of the Great Valley; but at its southern extremity there are several, one of which is of large size, having an area of not less than 700 square miles. This is Tulare Lake, which, together with Kern and Buena Vista lakes, receives the drainage of the southern part of the Sierra, by the Kern, Kaweah, King's, and other smaller streams. Tulare Lake is quite shallow, being only 40 feet deep; its banks are low and reedy (hence the name, Tulare, a place of reeds or tules), and in wet seasons it overflows them, and becomes greatly extended in area. At such times the excess of the drainage passes off into the San Joaquin; but in dry seasons the evaporation is so great that there is no discharge in that direction. The northern branch of the San Joaquin heads in the grand group of summits of which Mounts Maclure, Lyell, and Ritter are the culminating points; the southern rises on the north side of Mount Goddard. The united stream issues from the mountains at Millerton; and, after gaining the centre of the valley, it turns and runs at right

angles to its former course, receiving three important tributaries and several smaller ones on the east, but not a single permanent one from the west. The area of the Sierra drained by the San Joaquin is only about half that of which the Feather collects the surplus waters.

There are several large mountain lakes in California, some of which are of pure and fresh water, while others are alkaline, being without any outlet. The finest of these is Tahoe, which lies on the very summit of the Sierra, and at an elevation of about 6200 feet. It has a length of about twenty miles, and is 1500 feet deep, its water being extremely pure, as it contains only three grains of solid matter to the gallon. The overflow of this body of water passes off by the Truckee River, and enters Pyramid Lake, where it "sinks," or disappears by evaporation. Clear Lake is another beautiful sheet of water, in the Coast Ranges, and about the same length as Lake Tahoe, but much narrower and more irregular in shape. Owen's Lake is the "sink" of Owen's River, and is about eighteen miles long. Mono Lake is the sink of the streams rising in the Sierra between Mount Dana and Castle Peak. It is about fourteen miles long, and nine wide, and lies at an elevation of about 7000 feet above the sea-level. There are several other large alkaline lakes in Lassen and Modoc counties, which receive the drainage of the eastern slope of the Sierra, within the limits of the State. Death Valley is the sink of the Amargosa River, and it has evidently been once an extensive lake, although now only a mud-flat in ordinary winters, and a dry, alkaline, desert plain in summer. All these lakes and depressions show very plainly, by the terraces which surround them, that the water was formerly much more abundant, and stood at a higher level than it now does.

North of the parallel of 40°, where the Coast Ranges and the Sierra unite, and the Great Valley disappears, the country is extremely rough and very thinly inhabited. The seven counties which are included within the region north from the head of the Sacramento Valley to the State line had in 1870 a population of only 19,269, and they had all lost in numbers during the previous decade. The counties of Lassen, Siskyou, and Modoc, which are embraced in the north-eastern corner of the State, are chiefly covered with volcanic plains, very dry and barren, lying between precipitous, although not very lofty, ranges. The waters of this region have no drainage to the sea. These three counties, with an area as large as that of Belgium, had in 1870 a population of only 8175, or less than one to the square mile. The north-western corner of the State is also extremely rough and mountainous, and a large part of it quite uninhabitable. The ranges which intersect it, and which are known as the Siskyou, Salmon, and Scott Mountains, seem to be geologically the continuation of the Sierra Nevada. They are from 6000 to 8000 feet in height; but they have never been accurately mapped, and very little is definitely known about them, although gold washings have been carried on for many years in some of the valleys bordering the Klamath River and its tributaries.

That portion of California which lies to the south and east of the southern inosculation of the Coast Ranges and the Sierra, comprising an area of fully 50,000 square miles, is also very thinly inhabited, with the exception of a narrow strip along the coast. Nearly all of San Diego and San Bernardino counties belongs to the Great Basin system, having no drainage to the sea. Los Angeles County, however, has within its borders some of the most fertile lands in the state. These form a strip about twenty miles wide along the coast; the north-eastern half of the county on the other hand, is extremely barren. The region lying east of the Sierra Nevada, and between the crest of that range and the boundary of the State, chiefly divided between the two counties of Mono and Inyo, is also a very mountainous tract of country. Owen's River runs through it from north to south for a distance of 180 miles, emptying into the lake of the same name, lying at the south end of Owen's Valley, and with no outlet. Here the scenery is extremely grand, the valley being very narrow and the ranges on either side elevated from 7000 to 10,000 feet above the lake and river. The Inyo range, on the east, is quite bare and destitute of timber, and its summits are only occasionally whitened with snow for a few days during the winter, the precipitation being almost entirely cut off by the Sierra on the west. East of Owen's Lake are several parallel ranges of mountains; and beyond them, at a distance of about forty miles from the lake, is Death Valley, which is about 150 feet below the sea-level. The name was given in allusion to the fate of a party of emigrants, who perished here, many years ago, from thirst, and perhaps starvation. Between Owen's Lake and Death Valley are the Panamint Mountains, which have lately been the scene of considerable mining excitement. A portion of the extreme southern part of the State in San Diego County is also below the sea-level. Here is a depressed area of fifty miles in length, the width of which is unknown; in its lowest part it is over 300 feet beneath the level of the sea. Dry Lake occupies the greatest depression of this area at the entrance to the Coahuila Valley.

There are many fine points in the scenery of California, some of which have already become well known from the descriptions of pleasure-travellers who have flocked to the State from all parts of the world. The granite pinnacles and domes of the Highest Sierra opposite Owen's Lake; the snowy cone of Mount Shasta, rising 10,000 feet above the adjacent plains; the lovely valleys of the Coast Ranges, with their peculiar vegetation,—all these have their charms; but the point which is most attractive of all is the Yosemite Valley. This is situated in the Sierra, about 150 miles in a direct line, a little south of east, from San Francisco. Its elevation is 3950 feet above the sea, and it is hemmed in by cliffs varying from 2000 to 3000 feet in elevation. The principal features of the Yosemite, and those by which it is distinguished from all other known valleys, are—first, the near approach to verticality of its walls; second, their great height, not only absolutely, but as compared with the width of the valley itself; and finally, the small amount of talus or *débris* at the base of these gigantic cliffs. The waterfalls in and about this valley are also of wonderful beauty and variety. Those of the Yosemite Creek, which descend from the cliffs on the north side, are most remarkable for their height, which is, in the whole, not less than 2600 feet, but divided into three parts, with one vertical fall of 1500 feet. The Nevada and Merced Falls of the Merced River, which flows through the whole length of the valley, combine great height with a large body of water, and are wonderfully grand. The Half Dome is one of the most striking features of the Yosemite, its elevation being 4737 feet above the bottom of the valley, with an absolutely vertical face of 1500 feet at the summit, turned towards the Tenaya Fork of the Merced, above which it rises. The scenery of the cañon of the Tuolumne River, which flows parallel with the Merced, a few miles further north, is also extremely picturesque, and remarkable especially for the great number and variety of the cascades which occur at short intervals in the deep gorge, the walls of which are bare and almost vertical precipices, in places more than a thousand feet high. The river, which is not much less than a hundred feet wide, falls 4650 feet in a distance of twenty-two miles. A few miles farther down, the narrow gorge opens out into a beautiful valley, in many respects a wonderful counterpart

of the Yosemite, although inferior to it in grandeur. This is called the Hetch-Hetchy. Above the Yosemite Valley the scenery of the High Sierra is very attractive, immense conical knobs or domes of granite being a prominent and very characteristic feature of this and other portions of the Sierra. Mount Dana, a little over 13,000 feet in height, dominates over the region above the Yosemite; and from its summit, which is quite easy of access, a magnificent panorama may be had of the Sierra Nevada, with Mono Lake, nearly 7000 feet below, spread out like a map, and beyond it the lofty, and, in some instances, snow-clad ranges of the Great Basin, while several well-formed and very large volcanic cones are seen just to the south of the lake.

Climate.—The climate of California presents many features of interest, differing considerably from those obtaining in the Eastern and Mississippi Valley States, which have furnished a majority of the immigrants to the Pacific coast and Great Basin. There can be no doubt that emigration to California has, especially within the past few years, been greatly stimulated by the desire of people at the East to escape the sudden changes, the intense heats of summer, and the bitter colds of winter, which characterize the climate of the whole country east of the Rocky Mountains.

The climate of California is very different in different parts of the State, according to distance from the ocean, situation with reference to the mountain ranges, and altitude above the sea-level. But there are certain peculiar features which obtain all over the State. In the first place, the division of the year into two seasons—a dry and a rainy one—is the most marked general characteristic of the Californian climate. But, as one goes north, the winter rain is found to begin earlier and last longer; while, on the other hand, the south-eastern corner of the State is almost rainless. Again, the climate of the Pacific coast, along its whole length, is milder and more uniform than that of the States in a corresponding latitude east of the mountains. Thus, we have to go as far north as Sitka, in latitude 57°, to find the same mean yearly temperature as that of Halifax, in latitude 44° 39. And in going south along the coast, we observe that the mean temperature of San Diego is six or seven degrees less than that of Charleston and Vicksburg, which are nearly in the same latitude as San Diego, and situated, one on the Atlantic, the other on the Mississippi River. But, in addition, we notice that the means of summer and winter are much nearer the mean of the year in California than in the east. Thus, comparing Washington and San Francisco, we have—

	Mean of Year.	Mean of Summer.	Mean of Winter.
San Francisco,..	56	60	51
Washington,.....................	56·07	76·3	36·05

This condition of things is not so marked as we advance into the interior of California; but everywhere in the state the winters are comparatively mild, and the heat of summer is much less disagreeable in its effects, because the air is exceedingly dry and the evaporation proportionately rapid. The climate of San Francisco is indeed wonderfully uniform; and the bracing, cool air which sweeps in from the ocean during the afternoons of the summer, although not favourable to persons with weak lungs or sensitive throats, is the very breath of life for those who are in vigorous health. One great drawback to the enjoyment of the delightful climate of California, however, is the dust of summer, which seems, until one becomes accustomed to it, quite unbearable. A more serious difficulty in this State is the extreme variability in the amount of rain which falls from year to year; and this uncertainty is something which must always be present in the mind of the farmer as likely seriously to influence his future. Some years are so dry that the crops are almost an entire failure, except directly on the coast, or where artificial irrigation is practised; other years are so wet, that serious inundations occur. During the interval from 1850 to 1872, the yearly rain-fall ranged, at San Francisco, from 7·4 inches to 49·27 inches. In going southward from San Francisco, the mean rain-fall decreases along the coast, and at San Diego it is only about 10 inches. At Fort Yuma it is a little over 3 inches. In the Sierra the annual precipitation increases as we rise in altitude; it is almost entirely in the form of snow at elevations greater than 6000 or 7000 feet; and this snow, as it melts during the summer, furnishes a store of water of immense importance to the State, supplying, as it does, the numerous ditches or small canals, which have been built, in connection with great reservoirs high up in the mountains, for supplying the miners, and which are more and more utilized for agricultural purposes, as the placer-mining claims cease to be worked. As there is no fall of rain or snow of any consequence on the Sierra during the summer, the accumulated stock of the previous winter melts gradually, and after a succession of dry seasons, it almost entirely disappears from the summits of the range. If, on the other hand, two or more rainy winters follow each other, the crest retains a large amount of snow to add to the next year's stock. The climatic conditions are such, however, that there are no true glaciers formed anywhere in the Sierra, although the traces of former ones are everywhere visible along the highest part of the range. These ancient glaciers once covered the summits and extended quite low down in some of the valleys,—notably in that of the Tuolumne, where the ice-flow may once have been from thirty to forty miles in length. The walls of the Hetch-Hetchy Valley are beautifully scored and polished by former glaciers, which once entirely filled the upper portion of this grand cañon. The nearest approach to a glacier which at present exists in the Sierra is to be found on Mount Shasta, on the north side of which, and almost at the summit, are large masses of ice having many of the characteristics of the genuine glacier.

The winds of California are, during the summer, exceedingly regular in their movement. As the interior becomes heated by the sun, the air rises, and a current of colder air rushes from the sea to take its place. Wherever there is an opening, therefore, in the Coast Ranges down to the level of the sea, there the wind will blow through it fiercely during the hottest part of the summer day, towards the interior. Thus, in going from the Bay of San Francisco towards the mountains, or up either the Sacramento or the San Joaquin Valley, the wind will be with the traveller. In fact the current spreads out fan-shaped from that point, and reaches far up from the ocean. A very strong wind and cool and bracing weather at San Francisco are indications of exceptionally hot days in the interior. At night the breeze slackens, and usually ceases altogether, a light mist often enveloping the city of San Francisco. At the same time, the cooler air draws gently down the mountain slopes, in opposition to its direction during the day. In the interior, the days, in summer, are extremely warm, the thermometer sometimes rising to 120° in the shade, and 160° or 170° in the sun. The farther one goes from the Bay of San Francisco, the hotter it becomes. At night, however, the radiation is rapid, and the temperature falls, so that a warm covering is almost always needed. The south-eastern corner of California is exceedingly dry, and has a very high temperature. At Fort Yuma the mean of the year is 76°, and the heat in summer is almost intolerable, the thermometer ranging above 90°, sometimes for weeks, both by night and by day. Among the peculiarities of the Californian this is not one of the least striking, that, as one

leaves the Sacramento and San Joaquin plains, and travels into the mountains, it becomes quite perceptibly warmer, at least for the first 2000 or 3000 feet of ascent. Thus, the mean temperature of the year at Colfax, 2400 feet above the sea-level, was, for 1871, 1°·6, and for 1872, 1°·4 higher than that of Sacramento, which is only 30 feet above the sea. As high up as 8000 or 10,000 feet the days in summer are comfortably warm, and even on the high peaks of the Sierra, at 12,000 or 13,000 feet of altitude, at mid-day it is usually so warm that an overcoat is not needed. At night, however, at these elevations, it is almost always so cold that frost occurs, although occasionally it is very warm all night long, even at as great an altitude as 8000 feet. It adds very much to the pleasure of travelling in the High Sierra that the weather is, by day, almost all summer long, delightfully mild and clear, and without rain; so that one of the greatest discomforts to which tourists are exposed in Switzerland and most other regions of pleasure-travel is here entirely unknown.

Geology.—The geological structure of California is comparatively simple, although the extreme paucity of fossils in the rocks of the gold region for a long time rendered it impossible to ascertain the age of the auriferous belt. It is also true that, for similar reasons, the formations which make up the main body of the Coast Ranges were not easily made out. A geological survey was authorized by the legislature in 1860, and continued, with occasional stoppages, until 1874. In the published volumes and maps which have been issued in the course of this work, almost all that is known with accuracy in regard to the geology and mineral resources of the State may be found.

The Sierra Nevada first claims attention, as being the dominating range It has a central core or axis of granitic rock, which forms almost the whole body of the range in its southern portion, diminishing in width as it is followed towards the north. All the higher points of the Sierra, in its most elevated portion, are of granite. Farther north there are a few high peaks of metamorphic rock, and many of the summits are capped with volcanic materials. Flanking the granite is a very heavy mass of slaty metamorphic rocks, commonly known as the auriferous belt of the Sierra. This consists chiefly of argillaceous, chloritic, and talcose slates, with a great variety of other metamorphic rocks in smaller amounts, and some large, apparently isolated patches of limestone, which succeed one another in the line of direction of the axis of the range. The strike of the slates is usually parallel with that of the axis of the range, and their dip is, in general, at a high angle towards the east. Low down in the foot-hills, sandstones of Tertiary and Cretaceous age occur in considerable quantity. From the Stanislaus River towards the south, these strata are Tertiary, and they form quite a broad belt on White River and Pose Creek. On the American River, and north of it, the Cretaceous rocks are occasionally well developed and full of organic remains. All these beds rest in almost horizontal position on the upturned edges of the auriferous slates, showing that the elevation and metamorphism of the chain of the Sierra took place previous to the Cretaceous epoch. These beds are of marine origin; but there are very extensive masses of sedimentary materials higher up in the Sierra which are fluviatile and fresh-water deposits, and they are associated with great quantities of volcanic detritus and solid lava which has evidently come down from the higher portions of the chain. The eruptive materials do not usually lie where they were ejected, but seem to have been carried far from their original position by currents of water, as they are made up, in great part, of rolled or brecciated masses, and are interstratified with gravels and finely laminated clays. These latter often contain impressions of leaves and whole trunks of trees, usually silicified, as well as bones of land and aquatic animals. The character of these fossil remains indicates that the formation is of late Tertiary age, and it may be considered as Pliocene. Although the crest of the Sierra is frequently crowned by large masses of volcanic materials, there are no indications of present activity along the range, and only occasionally can remains of ancient crateriform openings be seen. In Plumas County, however, and especially in the neighbourhood of Lassen's Peak, there are several solfataric areas and well-formed cinder cones, some of which exhibit very marked appearances of recent action. From here northward, volcanic masses cover more and more of the higher regions, and almost the whole of the north-eastern corner of the State is exclusively occupied by rocks of this character. Lassen's Peak (10,577 feet) and Mount Shasta (14,440 feet) are both extinct volcanoes, and the latter has, near its summit, hot springs and indications of solfataric action. The auriferous slates of the Sierra contain occasional fossils; and, in quite a number of localities, these have been found in close proximity to well-marked and productive veins of quartz, which are now, or have formerly been, extensively worked for gold. These fossils are of Jurassic age, and no Silurian or Devonian forms have ever been discovered anywhere in the Sierra. In Plumas County, Triassic fossils have also been discovered, but only in one locality of limited extent. These are, however, identical with species belonging to the Alpine Trias, which have been found in large quantities, and in numerous localities, on the eastern side of the Sierra, and which prove that this interesting group of rocks has a wide distribution on the Pacific side of the continent. The limestone belt, already mentioned, appears to be entirely destitute of organic remains, except in the extreme northern part of the State, where, in one or two localities, it has been found to contain well-marked carboniferous types. Farther south, this rock has become much metamorphosed, and is in many places converted into marble, while its organic remains appear to have become entirely obliterated.

The Coast Ranges are made up almost entirely of Cretaceous and Tertiary marine strata, chiefly sandstones and highly bituminous shales. The Cretaceous rocks occur from the Cañada de las Uvas northward along the east side of the Coast Ranges, gradually occupying more and more space in a northerly direction. After passing the Bay of San Francisco, this formation makes up nearly the whole mass of the mountains, which grow more elevated and rougher towards the north, the rocks being much metamorphosed and broken by granitic intrusions. In the vicinity of Clear Lake (latitude 39°) there is a belt of volcanic materials, accompanied by hot springs, and solfataric action, crossing the ranges from east to west. The Coast Range mountains have been much disturbed, and in part elevated during the most recent geological epoch, as large masses of strata of Pliocene age are found in various localities to have been turned up on edge; but volcanic activity seems to have been more general and continued to a later date in the Sierra than in the Coast Ranges. Some of the granitic masses along the shores of the Pacific are more recent than the Miocene Tertiary, as strata of this age have been uplifted and turned up on edge by the protruding granite. Indeed, everything in the Coast Ranges points to great geological disturbances as having occurred at a very recent date. Among the illustrations of this condition of things, the changes produced by earthquakes in modern times may be cited. Like all the rest of the Pacific coast, California is liable to these disturbances, and this circumstance has undoubtedly had considerable influence in retarding the settlement of the State. No year has been known, since the conquest of the country by the Americans, so disastrous as were the spring

and summer of 1812; the destruction of life at that time would probably have been large if California had been as thickly settled as it now is. During the whole of May of that year the southern part of the State was violently agitated, and the disturbances continued with more or less severity through the entire summer. So frequent and violent were the shocks that the people abandoned their houses and slept on the ground. In September the missions of San Juan Capistrano and La Purisima were destroyed, and thirty or forty persons killed at the first-named place; also a considerable number at Purisima, but how many was never ascertained. At Santa Barbara a tidal wave rushed into the interior; but the inhabitants, having observed the previous recession of the sea, had fled to the adjacent high ground, and thus escaped destruction. In the year 1808, in the months of June and July, there were numerous shocks at the Presidio of San Francisco. On the 8th of October 1865 the whole region adjacent to the Bay of San Francisco was violently disturbed, and many buildings thrown down, while hardly one of brick or stone within the city itself escaped injury; but few lives were lost, although great alarm was felt. Since that time there has been no severe shock having its focus near the coast; but in 1872 the whole Sierra Nevada, and the adjacent State of Nevada, were most violently shaken, the centre of the shock having been along the axis of the range, from which the waves were propagated east and west with about equal velocity. Immense quantities of rock were thrown down from the granite pinnacles in the Highest Sierra. The small settlement of Lone Pine, in Owen's Valley, at the east base of the mountains, was completely demolished, and between twenty and thirty persons killed. Luckily the heaviest part of the shock was limited to a region hardly at all inhabited, so that the destruction of life was insignificant in comparison with the extent and violence of the disturbance. Lighter shocks continued to be felt, for two or three months after the first severe one, through the whole extent of Owen's Valley. The extinct or dormant volcanoes, of which there is a fine group midway in the valley between its two extremities, showed no signs of being affected by this exhibition of the seismic forces. There are in the Coast Ranges long and very straight fissures in the rocks, which have been produced by earthquakes in modern times; and these have, in some instances, been accompanied by changes in the relative level of the ground on each side.

Mining.—California was for many years chiefly known to the world as the region where gold was obtained in extraordinarily large quantities. The excitement occasioned by the discovery of the precious metal was very great throughout the United States, and this and the finding of an equally important auriferous region in Australia, only two or three years later, produced an immense effect on the commerce of the world, stimulating emigration in a way never before dreamed of. The existence of gold had long been known in California, and washings had been carried on in the southern part of the country, near the San Fernando Mission, for several years, having commenced there as early as 1841. No discovery had been made, however, which attracted much attention, or caused any excitement, previous to the occupation of the country by the Americans. In January 1848, a piece of native gold was picked up in an excavation made for a mill-race on the South Fork of the American River, at a place now called Coloma. It was several months, however, before the number of persons brought together by this discovery had become large; but, by the end of December, washing for gold was going on all along the foot-hills of the Sierra, from the Tuolumne River to the Feather, a distance of 150 miles. The first adventurers came from Mexico, the South American coast, and even from the Sandwich Islands. The excitement extended to the eastern Atlantic States in the course of the autumn and winter succeeding the discovery; and, in the spring of 1849, the rush of emigration across the plains, and by way of the Isthmus of Panama, commenced; and it was estimated that 100,000 men reached California during that year, among whom were representatives of every State in the Union. The emigration to the land of gold was continued, with but little abatement, during the three succeeding years; but the excitement fell off in a marked degree in 1854, at which time there was a decided reaction throughout the United States in regard to mining matters. The Californian discoveries had given rise to a general search for metalliferous deposits in the Atlantic States; and this had been followed by wild speculations, a great deal of money having been sunk in opening new mines, and in attempting to develop old ones which had never yielded anything of value. How many miners were actually at work in California at the time of the greatest excitement can only be a matter of conjecture. It is generally believed that not less than 50,000 men were engaged in mining for gold at the close of the year 1850. Those who had good opportunities for observing think that there were as many as 100,000 at work in 1852 and in 1853. At the time of their greatest productiveness, the yield of the Californian gold washings reached about sixty-five millions of dollars in value a year; this was from 1850 to 1853. If there were 75,000 miners actually employed at this time, the average amount obtained must have been fully $8 a day per man. The average is thought by many to have been as high as $20 a day during the year following the first discovery. At this time the diggings for gold were chiefly along the rivers. These were "flumed,"—that is, the water was taken out of the natural channel by means of wooden flumes,—and the accumulations of sand and gravel in the former beds were washed. All the small "gulches" or ravines leading down the sides of the steep and narrow valleys, or cañons, were worked over, either with or without the aid of water. These were the first and richest "placers," and in them the precious metal was most unequally distributed. Those who first got hold of the rich bars on the American, Yuba, Feather, Stanislaus, and the other smaller streams in the heart of the gold region, made sometimes from one to five thousand dollars a day; these rich spots were chiefly very limited in area, and after one was worked out, it might be days or weeks before another was found.

During the year 1851 the miners, not finding any longer room for employment on the river-bars, began to extend their "prospecting" to the higher ground, and it was not long before it was discovered that the so-called "high gravels"—that is, the detrital deposits of Tertiary age—contained gold, although the quantity was so small that washing it in the ordinary way was not profitable. This led, in 1852, to the invention of the "hydraulic process" of working the auriferous detritus, the idea of which is due to E. E. Matteson, a native of Connecticut. This process has now received an immense development, successive improvements having been made in the method and the machinery for applying it, until the results have become indeed wonderful. The "sluice" which is used with it, and, in fact, in all gold-washing in California at present,—almost without exception,—is also a Californian invention. Previous to its introduction, first the "rocker" and then the "tom" were employed. During the first years of the Californian excitement there was much wandering about within the State and in the adjacent territories in search of new "diggings," the miners seeming to have the fixed idea that somewhere an auriferous centre or focus would be found, vastly richer than any thing previously discovered. They were an excitable body of men, and frequently left

valuable localities in search of something better, always hoping that deposits of unheard-of richness would be developed. Occasionally a kind of frenzy would seem to seize on them, and thousands would flock to some new and perhaps distant locality, on the strength of newspaper reports, where many would perish from disease and starvation, the rest returning in poverty and rags. Thus, in 1855, the Kern River fever raged through the State, at least 5000 miners going to that distant region of the Sierra, only to find that the gold deposits were limited in extent, and already worked out. In 1858 the "Fraser River rush" occurred; and this was more disastrous to California than the most deadly pestilence would have been; for it caused a terrible amount of suffering. Nearly 20,000 men left the State for that remote region, where few met with even moderate success, while all suffered great privations, and many died, the survivors coming back in a state of complete destitution. The shallow "placer diggings" of California are now pretty well worked out, and the gold at present is chiefly obtained from the hydraulic mining operations and from the quartz veins. The deep or high gravels, as they are indiscriminately called, and which are worked by the hydraulic process, lie chiefly in Nevada, Placer, and Sierra counties, in the region extending between the branches of the American and Yuba rivers. These gravels are usually associated with heavy deposits of volcanic materials, and, indeed, they are often entirely covered by immense flows of lava, under which the workings are carried by means of tunnels.

All the operations connected with the exploitation of the large hydraulic "claims" are usually on a grand scale. As much as twenty-five, or even fifty, tons of powder are sometimes used in a single blast to loosen the gravel, so that it can be acted on with ease by the jet of water thrown from the "pipes." To give an idea of the force of the agent thus employed, it may be stated that, when a six-inch nozzle is used, under a head of 300 feet, as is sometimes done, not less than 1600 cubic feet of water are discharged in one minute, with a velocity of 140 feet per second. The water, as it thus issues from the nozzle, feels to the touch like metal; and it retains its cylindrical form unbroken until it strikes the gravel bank at a distance of a hundred or more feet. The detritus, thus powerfully acted on, crumbles rapidly, and the disintegrated material is carried by the current into the sluice-boxes, where it leaves its auriferous particles in the "rifles," which are chinks or cavities between the bars or blocks of wood or stone with which the bottom of the sluice are lined. Gold-mining in the solid rock—or quartz-mining, as it is usually called, because the gangue or vein-stone which carries the gold is almost exclusively quartz—is also extensively carried on in California, having been begun as early as 1851. The mines are scattered over the State from San Diego to Plumas counties; but the most important and productive ones are in Amador and Nevada. The distribution of the gold in the veins is exceedingly irregular, and, consequently, the business of quartz-mining has been, in most cases, a very uncertain one. A large number of the principal workings are on, or in the neighbourhood of, what is known in California as the "Great Quartz Vein," or the "Mother Lode," an immense development of quartz, which has been traced from Mariposa County to Amador, over a distance of eighty miles,—not continuously, but in a series of nearly parallel belts, or lenticular masses, with barren intervals between them; these have very nearly the same direction, and are parallel with the axis of the Sierra. It is on the Great Quartz Vein that the celebrated Mariposa mines are situated; which, however, have not, on the whole, proved successful. In the same position are the mines of Amador County, among which the one formerly called the Hayward Mine is the best known, and for a long time one of the most profitable. The mass of quartz worked in this mine was of great size, although of low tenure in gold. It was, for some years, the deepest mine in the country; but several of those on the Comstock Lode in Nevada have now attained a considerably greater depth.

Silver-mining has been attempted in many localities in California, and much money spent in trying to develop the argentiferous lodes which have from time to time been discovered. A few years ago, there was a great excitement on the very summit of the Sierra in regard to supposed valuable silver-bearing veins, and particularly at a locality called Meadow Lake, in Nevada County. Quite a number of mining camps and towns were built up, one of which had for a time several thousand inhabitants. Nothing permanently valuable was discovered, however, and the region was soon entirely abandoned. The most persistent efforts have been made, for the past ten years, to work argentiferous deposits in the volcanic rocks near the summit of the Sierra, in Alpine County, at and near Silver Mountain. Although it does not appear that any mine in this region has been successful, the expenditure is still kept up. Slate Range, a little to the east of Owen's Lake, was the scene of considerable excitement some ten or twelve years ago, rich silver ores having been discovered there; but it was found that mining could not be made profitable in that distant region destitute of water and fuel. Quite recently, the Panamint Range, in the same vicinity, has attracted much attention. The only paying silver mines in the State seem, however, to be those in the Inyo Range, at Cerro Gordo, where the ore is chiefly galena, rich in silver, and also containing considerable gold. The yield of this district in the year 1872 was nearly a million of dollars in value, six-tenths of which was silver. Silver.

Quicksilver has been extensively mined in California, the mine of this metal at New Almaden, Santa Clara County, having been worked previous to the gold excitement. All the workable deposits of cinnabar thus far known to exist are situated in the Coast Ranges, and they are chiefly limited to the metamorphic Cretaceous group of rocks, in which they are associated with serpentine, imperfect jasper, hornstone, and chalcedony. By far the most important mines are those at New Almaden, a few miles west of San José. These produced, in their palmy days, during the years 1853 to 1857, and 1861 to 1869, from 2,500,000 to 3,500,000 lb of quicksilver per annum. In 1870, the production had fallen off to 1,000,000 lb. The total production of the New Almaden mines between 1850 and 1870 was a little over 40,000,000 lb. The New Idria Mine is in Fresno County, about ninety miles south of New Almaden. This has also been, for some years, a quicksilver-producing locality of considerable importance. Cinnabar also occurs in considerable quantity at numerous places north of the Bay of San Francisco, in Napa and Lake counties. The most important mine in this region is the Redington, near Knoxville, in Lake County. The export of this metal from California was, in former years, very large, reaching, in 1868, the amount of 44,506 flasks, or 3,404,709 lb; in 1870, it was only 6,359 flasks, although the production for that year was estimated at 28,600 flasks, or 2,187,900 lb, of which 12,000 were the product of the New Almaden mine, 7600 of the New Idria, and of the remainder, about one-half was from the Redington, and the rest from various smaller mines north of the Bay of San Francisco. Quick-silver.

Copper ores occur in a great many localities within the limits of the state of California, and at some of these a large amount of work has been done, although at the present time there does not seem to be a single locality where the ores of this metal are now mined. Quite large masses of nearly pure native copper, mixed with the red oxide have Copper.

been found in the north-western corner of the State, and also farther south in the Coast Ranges. No permanent mine has, however, yet been developed at any point on the west of the Great Valley. In the foot-hills of the Sierra, at a place known as Copperopolis, in Calaveras County, there is a very extensive deposit of copper ore, which was actively mined some ten years ago, producing very largely for a time. The mass of ore here was, in places, as much as 30 feet wide, although not of high grade. In 1864 the value of the shipments of copper ore from California was a little over a million dollars; this was almost all from one mine, **Tin.** the Union, at Copperopolis. Tin has been discovered at one locality in the southern part of the State, in the Temescal Range, about forty miles south-east of Los Angeles; and mining was attempted here, but the locality has been for some time abandoned. Zinc and lead occur, in the form of the sulphuret, in a great number of the quartz veins of the gold-bearing belt; they are generally present, however, only in small quantity, and have not been made the object **Iron.** of mining enterprise. Iron ores are also found, in several localities, in large quantity; the want of suitable cheap fuel has prevented these ores from being utilized, and all the iron consumed on the Pacific coast comes from the Atlantic States **Coal.** or from Great Britain. Coal of the true Carboniferous period does not occur anywhere on the North American continent west of the eastern base of the Cordilleras; but there are, at various points, extensive deposits of lignite and imperfect coal; in some of these, the woody structure is entirely obliterated, and the substance may with propriety be called coal. It is rarely the case, however, that it does not contain a large percentage of water. These deposits are both of Tertiary and Cretaceous age; but at the localities extensively worked in California and on Vancouver Island, the beds belong exclusively to the last-named group. The only mines of coal of any consequence in California are those of Monte Diablo, so called because situated on the north slope of that mountain, and a few miles from the entrance of the San Joaquin River into Suisun Bay. The coal raised at these mines is of tolerably good quality for domestic use; but it cannot be used for ocean steaming or for making gas, as it contains a large amount of sulphur, and from 10 to 12 per cent. of water. These mines have yielded of late about 175,000 tons per annum. There is also a large deposit of about the same quality, and the same geological age, on Eel River, in Mendocino County. This is too far from navigable water to be utilized at present, as it cannot compete with the more accessible deposits on Vancouver Island, and at Bellingham and Coos bays, or with those more recently opened near Seattle in Washington **Petroleum.** Territory. Petroleum was thought likely, at one time, to become of great importance as a product of California, and several millions of dollars were expended in boring and searching for it, but almost entirely without success. The great bituminous slate formation, of Miocene age, which stretches along the coast from Monterey to Los Angeles, does, indeed, contain a large amount of combustible matter, which may at some future time become of economical value. At present there seems to be no immediate prospect of this; and it is certain that the geological conditions are such that flowing wells, like those of Pennsylvania, will not be found **Borax.** on the Pacific coast. Borax is one of the mineral productions of California, which is becoming of some importance. The value of the exports of this article from San Francisco in 1873 was over $400,000. Of this, however, a considerable portion came from the adjacent State of Nevada. Sulphur has been mined in several localities, to some extent, **Building stones.** for the manufacture of sulphuric acid. Marble occurs in many places in the Sierra Nevada, and is quarried for ordinary architectural purposes. Granite and freestone are abundantly distributed; the former exists in inexhaustible quantity on the line of the Central Pacific Railroad, the latter near San Francisco and in many other places in the Coast Ranges.

Mam[mals]. *Fauna.*—Somewhat over a hundred species of mammalia have been found in California. Among the most interesting are the grizzly bear (*Ursus horribilis*), formerly very common, but now only met with in out-of-the way localities; they are especially abundant in the Coast Ranges south of Monterey—the Santa Lucia Range. They are savage and powerful animals, but do not care to attack men unless suddenly intruded upon, or when with their young. The black bear (*U. americanus*) is still pretty common in the higher parts of the mountains; and the so-called cinnamon and brown bear are supposed to be varieties of this species. The sea lions (*Eumetopias stelleri*) are of little value commercially, but they excite a great deal of interest on account of their size, their strange gambols and extraordinary noises; they abound on the coast, and especially on the Farallones. Visitors to San Francisco from abroad rarely fail to go to the beach opposite Seal Rock, an isolated point near the city, and almost always crowded with these animals, whose curious habits can be watched from the mainland at a short distance. The beaver (*Castor canadensis*) was formerly very common in the State, and many are still left. The spermophiles, or ground squirrels, are extremely abundant, and great nuisances; the ground is often honey-combed for miles with their burrows. The large hare-squirrel and the tiny pine-squirrel are common in the mountains. Gophers are very troublesome to the farmers; there are five species of them, the largest (*Thomomys bulbivorus*) being abundant in the central portion of the State near the coast. The elk (*Cervus canadensis*), formerly found in great numbers in California, is now almost exterminated, unless it be in the northern counties, in the recesses of whose forests they may be still occasionally seen. The deer (*C. leucurus*) is quite common, at a distance from settlements, and especially in the southern High Sierra. A few antelopes are still met with; but when the Americans first entered California, these animals were seen in immense herds all over the plains of the San Joaquin and Sacramento valleys. The mountain sheep (*Ovis montana*) is also nearly exterminated. **Birds.** Of birds, over three hundred and fifty species have been described as occurring in California. Some of the most characteristic of this State are the road-runner (*Geococcyx californianus*), nearly allied to the cuckoo, but like a pheasant in its habits of running and inability to fly; the California woodpecker (*Melanerpes formicivorus*), which has the curious habit of boring holes in the bark of trees and filling them with acorns, which fit most accurately and closely in the cavities thus made. The object of this arrangement appears to be, to allow the grubs to fatten inside the acorns, which thus in time are found to contain a nice meal for the provident bird. The California vulture (*Cathartes californianus*), the largest flying bird in North America, is not limited to this State, but is common there. The sage hen (*Centrocercus urophasianus*) is a fine game bird, found in abundance on the east slope of the Sierra, among the "sage-brush." Two species of quail are very abundant, and very characteristic, in the State,—*Oreortyx pictus* and *Lophortyx californica*. They both have elegant crests of long narrow feathers, in one species turned backwards, in the other forwards. **Fishes.** Fish are very abundant on the coast; salmon are caught in great numbers in the Sacramento River, and are an important article of food, especially in Oregon. Sturgeon are also abundant: and as their flesh is sold at a very low price, it is much eaten by those who are obliged to be economical. The salmon is also in this respect a very valuable fish. The so-called "rock-fish" are among the fish most abundant in the San Fran-

cisco market, and perhaps the most characteristic. They belong to the genus *Sebastes*, and there are several species of different colours. Smelts are abundant; but they are not true smelts, and are inferior to them as an article of food. There are several fish of the flat-fish family, and called soles and turbot; although in no case are the species identical with those found on the Atlantic coast or in Euroope. The Tom-cod is abundant in the winter months, and although small, it is one of the best of the fishes of the coast. The barracouta (*Sphyræna argentea*) is decidedly the best-flavoured fish found on the coast; but it is not at all common. The oysters of the Californian coast are small; but foreign ones are planted in the Bay of San Francisco, where they grow rapidly. Hard-shell clams and mussels are abundant, and are eaten in considerable quantity. The haliotis called *Abelone* is taken in great numbers, but eaten exclusively by the Chinese. Crabs, lobsters, and shrimps, are abundant on the coast; and they are used to some extent as food. The variety of species of the crab family is very great, and some of them are very large. Quite serious attempts have been made, under the auspices of the United States Fish Commissioner, to introduce some of the eastern fishes into Californian waters, especially the shad; but these trials have not yet led to any satisfactory results.

Flora.—The vegetation of California has many features of interest The great extent of the State and the varied character of its surface are strongly impressed upon its flora. A great number of botanists and professional seed collectors have visited California from time to time; but no general review of all the species has ever been made, although such a one is now in progress under the auspices of the Geological Survey. The entire number of species found in the State is estimated at about 2500. There is not so great a variety of forest-trees as would naturally have been expected; and many of the most useful varieties are entirely wanting. The forests have, in places, and especially along the Sierra, at an elevation of from 2000 to 6000 or 7000 feet, a character of grandeur hardly surpassed in any part of the world. Many of the trees are of gigantic dimensions. Coniferous trees greatly predominate in the densely wooded portion of the State. Of the pines, the sugar pine (*Pinus Lambertiana*) is perhaps the finest tree, reaching occasionally 300 feet in height. Its wood is valuable for inside work, and it is much used in the Sierra, where the tree is chiefly found. This, and the *Pinus Coulteri*, have cones of great size. *Pinus sabiniana*, the digger pine or nut pine, is the characteristic tree of the foot-hills of the Sierra, where it occurs associated with the black oak (*Q. sonomensis*), sparsely scattered over the hill-sides, and never in dense forests. This is the foot-hill arboreal vegetation. Rising a litle higher, at an elevation of 3000 to 5000 feet, the pitch pine (*P. ponderosa*), the sugar pine, the white or bastard cedar (*Libocedrus decurrens*), and the Douglas spruce (*Abies Douglasii*) are the predominating and characteristic trees. Still higher, the firs come in, namely the *Picea grandis* and the *amabilis*, as well as the tamarack pine (*P. contorta*). This belt ranges at from 7000 to 9000 feet elevation in the Sierra, through the central portion of the State. The big tree (*Sequoia gigantea*) belongs to the same belt as the sugar pine, Douglas spruce, and pitch pine. This tree occurs in groves or patches from latitude 36° to 38° 15′, nowhere descending much below 4000 feet in elevation, or rising above 7000. There are eight or nine of these patches of big trees, and by far the largest is that one which extends along the tributaries of King's and Kaweah rivers, about thirty miles N.N.E. of Visalia. This belt is probably over ten miles in length. the trees are, however, not grouped by themselves, but stand scattered among other species. The tallest big tree yet discovered measures 352 feet in height. The circumference of the largest, near the ground sometimes reaches nearly 100 feet. Many are over fifty feet in circumference, at 6 feet above the ground. One in the Calaveras Grove, which was cut down, measured 24 feet and $1\frac{1}{2}$ inches in diameter, without the bark, at 6 feet above the ground; this would probably have measured about 27 feet with the bark. Its age was a little less than 1300 years. As the big tree is exclusively limited to California and to the Sierra Nevada, so the only other species of the same genus, the redwood (*S. sempervirens*), is peculiarly a Coast Range tree. It is found chiefly in the counties north of San Francisco Bay, where it forms magnificent forests, exclusively limited to this one species. A few of these trees may be found beyond the line dividing the State from Oregon; but this species, as well as the big tree, is peculiarly Californian. The wood, although brittle and splintery, is durable, and much used for building purposes in San Francisco. In size, this tree is very little inferior to the *Sequoia gigantea*. It appears that this species cannot thrive except where it is frequently visited by the ocean fogs. Another characteristic Coast Range tree is the California laurel (*Tetranthera californica*), which has a beautifully grained wood much valued for cabinet-work. Some species of Coniferous trees occurring in the Coast Ranges are very limited in their range; as, for instance, the well-known ornamental tree, the *Pinus insignis*, which is found near Monterey, and the Cypress (*Cupressus macrocarpa*), of which there is a magnificent grove at Cypress Point, near Carmelo Bay. The *Abies bracteata* is another of these trees of singularly limited distribution. The Douglas fir, or spruce, on the other hand, is spread over a vast area in California, Oregon, Washington Territory, and through the Rocky Mountains. Of shrubs, the manzanita (*Arctostaphylos pungens*) is a very characteristic one, being found all over the Sierra Nevada in dry places; the California buckeye (*Æsculus californica*) is another low-spreading tree or shrub, abundantly distributed through the Sierra and in the coast valleys; and another shrub, called by the Spanish the chamiso (*Adenostema fasciculata*), is widely scattered up and down the Sierra and Coast Ranges. The chamiso and the manzanita, with a variety of shrubby oaks and other thorny plants, when combined together in a dense and sometimes quite impenetrable undergrowth, form what is called by the Spanish a "chaparral." If the chamiso occurs alone, the thicket is known as a "chamisal." The oaks are very characteristic trees of the California Valley, to which they often give by their graceful grouping in isolated clumps a wonderfully park-like character. The burr oak (*Q. lobata*) is the most striking of these trees, growing to a great size, and having peculiar, gracefully-drooping branches. The elm, the hickory, the beech, the chestnut, and many other of the most characteristic and useful trees of the Eastern States, are entirely wanting in California. One valuable variety of the ash occurs, but only in limited numbers, and there is no species of maple which is suitable for use. Indeed, there is no wood on the Pacific coast from which any part of the running-gear of a good waggon can be made; consequently there is a large importation into the State, from the Atlantic side, of timber for this and similar purposes; while, on the other hand, the ornamental forest-trees of California are already widely spread over the world.

Agriculture.—The amount of land in California, which can properly be called tillable, cannot be stated with any approach to accuracy; and the estimates would vary, according as the peculiarities of the climate, and the possibilities of artificial irrigation, were taken into consideration. A large part of the State consists of barren deserts or precipitous mountains, either too rough or too

elevated, or too dry for cultivation under any circumstances. A considerable portion of the Great Valley will not yield sufficiently to pay for cultivation, unless a thorough system of irrigation should be adopted. Extensive districts produce valuable crops when the season has been wet enough; and an excess of rain which is injurious in one part of the State is of great benefit in another. The number of acres of "improved land" in the state, as given by the census of 1870, was 6,218,133; but Mr Hittell, in the third edition of his *Resources of California*, published in 1867, estimates the amount of cultivated land at only 1,000,000 acres. The same authority says, "Not more than one acre in ten could now be tilled profitably." Allowing the census returns to be correct, the proportion of improved land would be about one-eighteenth of the whole. Owing to the peculiarities of the climate, and especially its mildness in winter, and the dryness of the summer, the whole system of cultivation is very different in California from what it is in the Mississippi Valley and the Eastern States. If the season is favourable, that is, if rain falls in abundance by November, so that the ground becomes soft enough to plough, then sowing is begun at once, and the best crops are raised when the "latter rains,"—as they are usually called,—which fall in March and April, are tolerably abundant, and yet not so much so as to cause inundations. June and July are the harvest months, and the grain can remain out of doors during the whole summer without injury, or until it can be conveniently carried away, barns being little used. Almost everything, except ploughing, in connection with agricultural work, is done on a large scale, with the help of machinery; and the profitable farms are usually of great size, comprising many thousand acres. According to the census of 1870, the amount of the principal productions of the soil was in that year as follows:—wheat, 16,676,702 bushels; barley, 8,780,490 bushels; wool, 11,391,743 ℔; potatoes, 2,049,227 bushels; wine, 1,814,656 gallons; butter, 7,969,744 ℔. Barley is the most certain crop raised, and wheat and wool are the most important for exportation. The Californian wheat is of the finest quality, and is largely shipped to foreign countries. In 1873, according to the statistics of the San Francisco *Commercial Herald*, the shipments of wheat and flour were as follows:—to Great Britain, of flour, 245,708 barrels, and of wheat, 9,152,303 quintals; to China, flour, 125,891 barrels; to Central America, flour, 42,835 barrels; to Japan, flour, 9566 barrels; to Panama, flour, 12,777 barrels; to Australia, wheat, 22,400, bushels; with other smaller amounts to numerous ports in and about the Pacific. The total shipments for the years 1871–1873 were as follows:—

	Flour, barrels.	Wheat, quintals.	Barley, quintals.
1871	232,094	1,311,679	12,371
1872	247,088	6,071,383	176,153
1873	479,417	9,175,960	260,890

Fruit is an item of great importance in the agriculture of California, the quantity raised being very large, and the quality excellent. The pear, plum, apricot, and grape are especially good; and large quantities would be sent to the Eastern States if the distance were not such as to make it difficult and expensive to transport this bulky and perishable commodity. A large amount of capital has been invested in the manufacture of wine. As early as 1861 a million of gallons were made in that year, and in 1870 the product was estimated at 2,500,000 gallons. The principal wine-producing districts are in the vicinity of Sonoma, north of the Bay of San Francisco, and in the region about Los Angeles. The value of the exports of wine has not increased much in the last three or four years; in 1873 it was $356,373. The quantity of wine which might be produced in California, if there were a market for it, would be very large; but the quality is not all that could be desired, although the persons engaged in this business are sanguine in the belief that, with time and experience, the difficulties will be overcome, and their products be largely in demand in the Eastern States where at present there is scarcely any sale for them.

California is a country particularly adapted to raising sheep, and the wool interest is a very important one. The winters are so mild that shelter for the flocks is not required, and they have no other food than that which they pick up for themselves on the lower plains in winter, and in the higher mountain valleys in the summer. The summit valleys of the Sierra are literally alive with sheep during the months of July, August, and September, countless herds being driven there from the parched-up plains at the base of the range. In 1873, according to the *Commercial Herald*, about 30,000,000 ℔ of wool were exported from San Francisco, and 3 000 000 ℔ consumed in the home manufactories.

Manufactures.—The value of the manufactures of California is given, in the census report of 1870, at $66,594 536 the increase having been rapid within the past ten years; previous to 1860 almost every manufactured article used in the State was imported from the East or from Europe. The great distance of the Pacific coast from the manufacturing districts of the world offers a heavy premium for the establishment of various industries, especially for those which furnish bulky and inexpensive products, such as wooden wares, agricultural implements, machinery, coarse articles of clothing, and vehicles. The drawbacks are, the high price of labour, where the Chinese cannot be employed; the absence of good coal, and the scarcity of other fuel; the distance of the water-power from the principal markets, and its high cost at all points, which is due to the necessity of building long canals, dams, and other appliances for storing and utilizing the water; and the absence of those woods which are most needed for the innumerable uses to which this material is put in manufacturing. There are certain articles, however, which have to be made in California, because the people of other countries find it difficult to ascertain exactly what is needed to meet the requirements of the Pacific coast. Thus, mining machinery is a very important article of Californian manufacture, and many improvements have been made in this department, called out by the peculiar wants of this State and of Nevada. The manufacture of heavy woollen goods, especially blankets, is an item of importance, there being three large establishments of this kind in San Francisco. Leather is tanned in considerable quantity in the coast counties, and the exports of this article amounted in value, in 1872, to the sum of $258,692. Boots and shoes are manufactured in large quantity for home consumption and from native leather.

Population.—The population of California is concentrated in and around San Francisco; and it becomes rapidly less dense as one recedes from the centre. The extreme northern and southern counties are very thinly inhabited. The central part of the State, embraced between the parallels of 36° 20′ and 40° including only one-third of its whole area, contained in 1865 over ninety-five per cent. of the population. A region of 4000 square miles adjacent to the Bay of San Francisco includes probably half of the entire number of inhabitants in the State,—San Francisco alone, by the last census, having 38 per cent. of the whole. The reasons of this concentration around the bay are not difficult to find; the climate is more agreeable and healthier, and the valleys which open out to its waters are the most delightful and most fertile portions of the state. The desire of concentration is strongly felt in a region where the country is so thinly settled, and where the facilities

of communication are not great, and schools and churches far apart, or wanting altogether. Those who have made fortunes in mining come to "the Bay" to spend them; those who have lost their all, or become "strapped,"—to use the miner's phrase,—go to the great city to find employment. And San Francisco is not only the metropolis of California, but of the whole Pacific coast. There is not another city or town having one-tenth of its population anywhere from Alaska to Panama. It has the only really good harbour along the entire line of coast from Lower California north to Puget Sound, that of San Diego excepted, and this has a desert region behind it, where settlements cannot be made. The population of San Francisco, by the census of 1870, was 149,473, having increased to that number in the previous decade from 56,802, the gain of the city being relatively considerably greater than that of the State itself. Sacramento city, the capital, is the only other town in California which has as much as one-tenth of this number. It is claimed, indeed, that the present (1876) population of San Francisco is not less than 250,000, the increase having been unusually large during the past year, which has been, on the whole, a very prosperous one for the State. The other large towns are—Sacramento, 16,283; Oakland, 10,500; San Jose, 9089; Grass Valley, 7063; and Los Angeles, 5728,—all these figures being those of the census of 1870. The population of the whole State, according to the same authority, was, in 1870, 582,031, an increase of 53 per cent. since the previous census of 1860. The growth of California has not been in the years from 1860 to 1870 as rapid as in the decade preceding that, when the increase amounted to 310 per cent. Remarkable as has been the development of this State, it does not equal that of some of those of the Mississippi Valley during the same period. Thus Iowa gained more between the years 1860 and 1870 than did California, although having only one-third of the area of that State; and in the decade previous to that her gain was relatively nearly equal to that of the Golden State, and actually twice as great. The actual increase of population in Massachusetts, with its area of only 7800 square miles, was greater in the years 1860–1870 than was that of California.

The brilliant discoveries of metalliferous deposits in Nevada, wholly developed within the past fifteen years, have added much to the wealth and resources of California, for the ties of business are nearly as strong between the two States as if there were no political line of division between them. Nearly all the capital invested in the region at the eastern base of the Sierra came from the Pacific side of the mountains, and most of the machinery used there has been constructed in San Francisco. Nevada takes a large amount of the surplus agricultural products of California, and gives bullion in exchange, that being the only thing she produces for exportation.

The Chinese element in California is a peculiar and interesting feature. By the last census there were 49,31 of that race in the State. They are settled in great numbers in San Francisco, where they are house-servants, and operatives in the manufacturing establishments, which could not be successfully carried on with white labour. They also work the abandoned placers, although the amount of their gains in this operation must usually be very small, as they are only allowed to occupy spots supposed by the white men to have been quite worked out. "The white miners have a great dislike to Chinamen, who are frequently driven away from their claims, and expelled from districts by mobs. In such cases the officers of the law *do not* ordinarily interfere; and, no matter how much the unfortunate yellow men may be beaten or despoiled, the law does not attempt to restore them to their rights or avenge their wrongs" (Hittell, in *Resources of California*, 3d ed. p. 375).

General Considerations.—Finally, California has in its favour its immense extent of area, its variety of physical configuration, the fertility of a portion of its soil, and, above all, the mildness and attractiveness of its climate. Its position on the Pacific is one which justifies the confident expectation that the commercial interests of San Francisco will continue to increase in magnitude, since it must always concentrate the trade of an immense area. There are some conditions which may eventually operate powerfully to retard the development of this State. Of these the most important is, perhaps, the wastefulness of the present method of agriculture, by which crops are continually taken from the soil, and nothing restored to it. Another serious matter is the constant wholesale destruction of the forests going on in the Coast Ranges and in the Sierra; there is reason to fear that this will eventually have a disastrous effect on the regimen of the rivers, causing inundations in the spring and excessive droughts in summer. The danger from earthquakes has already been alluded to; and there is no question that it has had and will continue to have an influence in retarding the growth of the State, as there is not the least doubt that it similarly affects the whole South American Pacific coast. The facility with which the legislature can be manipulated, and brought to sanction schemes fraught with injury to the people, is not a circumstance peculiar to California; although, in several instances, heavy blows have in this way been struck at the prosperity of San Francisco. The distrust of the legislature often leads the people to reject that which is good, from the fear that an undertaking which looks well at the start may be so managed as to result in ruin. Thus, it seems impossible to carry out any general system of irrigation, or of forest culture and preservation, desirable as these things may be, because the people have no confidence in anything which has to be managed by the legislature, or which can be interfered with by that body at any time, and diverted to the subservience of private ends, to the injury of the public. (J. D. W.)

CALIGULA, Caius Cæsar, the third of the Roman emperors, was the son of Germanicus and Agrippina, and was born in 12 A.D. He was brought up in his father's camp among the soldiers, and received the name Caligula, from the *caligæ*, or foot-soldiers' shoes, which he used to wear. In 32 he was summoned to Tiberius, who was then living at Capreæ, and did all in his power to ingratiate himself with the tyrant. Perhaps about 35 he married his first wife, Junia Claudia, who died in the following year. Caligula seems then to have resolved upon obtaining the succession to the empire. For this purpose he leagued himself with Macro, commander of the prætorian guards, whose wife he had seduced, and there can be no doubt that the death of Tiberius was hastened by one or both of them. The senate conferred the imperial power upon Caligula alone, although Tiberius, the grandson of the preceding emperor, had been designated as co-heir, and he entered on his first consulship in July 37. For an account of his reign and character see Roman History.

CALIPH, or Khalif, the sovereign dignitary among the Mahometans, vested with an almost absolute authority in all matters relating to religion and civil polity. In the Arabic it signifies *successor* or vicar, the caliphs bearing the same relation to Mahomet that the popes, in

the estimation of Roman Catholics, bear to St Peter. It is at this day one of the titles of the grand seignior or sultan, who claims to be successor to Mahomet, through the line including Abu-Bekr, Oman, and Othman (the Sunnite view), and also of the Sophi or Sufi of Persia as claimant through Ali (the Shiite view). The history of the rule of the Sophis may occasionally remind the student of the saying current respecting Russian autocracy some fifty years ago, that it was "despotism tempered by assassination." When Louis XIV. was one day, in the presence of some courtiers, extolling the government of the Sophis as something approaching to an almost ideal excellence, the Marshal d'Estrees replied, "But, sire, I have seen three of them strangled during my lifetime." One of the chief functions of the caliph, in his quality of imaum or chief priest of Islamism, was to begin the public prayers every Friday in the chief mosque, and to deliver the *khootba* or sermon. In after times they had assistants for this latter office; but the former was always performed by the caliph in person. The caliph was also obliged to lead the pilgrims to Mecca in person, and to march at the head of the armies of his empire. He granted investiture to princes and sent swords, standards, gowns, and the like, as presents to princes of the Mahometan religion, who, though they had thrown off the yoke of the caliphate, held of it as vassals. The caliphs usually went to the mosque mounted on mules; and the Seljukian sultans, though masters of Baghdad, held their stirrups and led their mules by the bridle some distance on foot, till the caliphs gave them the sign to mount on horseback. At a window of the caliph's palace there always hung a piece of black velvet 20 cubits long, which reached to the ground, and was called the *caliph's sleeve;* this the grandees of his court kissed daily with great respect. After the destruction of the caliphate by Hulagu, the Mahometan princes appointed a particular officer in their respective dominions to sustain the sacred authority of caliph. In Turkey this officer is called *mufti*, and in Persia *sadne.*

The successions of caliphs continued from the death of Mahomet till the 655th year of the Hegira, when Baghdad was taken by the Tatars. After this, however, there were persons who claimed the caliphate, as pretending to be of the family of the Abbassides, and to them the sultans of Egypt rendered great honours at Cairo, as the true successors of Mahomet; but this honour was merely titular, and the right allowed them only in matters of religion; and though they bore the sovereign title of *caliphs*, they were subjects and dependents of the sultans. In the year of the Hegira 361, a kind of caliphate was erected by the Fatimites in Africa, and lasted till it was suppressed by Saladin. Historians also speak of a third caliphate in Yemen or Arabia Felix, erected by some princes of the family of the Jobites. The emperors of Marocco assume the title of *grand scherifs*, and pretend to be the true caliphs, or successors of Mahomet, though under another name. For particulars concerning the caliphs and caliphate see works bearing on Mahometan rule, such as Ockley's *History of the Saracens;* Gibbon's *Decline and Fall*, chap. li.; Von Hammer, *Histoire des Ottomans;* and for a brief survey, Freeman's *History and Conquests of the Saracens*, Oxford, 1856. See also articles ABBASSIDES and MAHOMETANISM.

CALISTHENICS. See GYMNASTICS.

CALITRI, a town of Italy, in the province of Principato Ulteriore and district of Sant' Angelo de' Lombardi, about 40 miles S.E. of Benevento. It is situated on an eminence near the River Ofanto, and is supposed to occupy the site of an ancient town called *Aletrium*. Its principal buildings are the parish church and a Benedictine convent. Population, 6629

CALIXTUS, the name of three different popes or bishops of Rome. Little is known of CALIXTUS I., bishop of Rome from about 220–226 A.D., during the reigns of Heliogabalus and Severus. CALIXTUS II., Guido of Vienne, was elected in 1119, after the death of Gelasius II. In 1122 he concluded with the Emperor Henry the important treaty of Mentz, by which the mutual rights of the church and the empire were definitely settled. He died in December 1124. CALIXTUS III., Alphonso de Borgia, was raised to the Papal chair in 1455 at a very advanced age. He was feeble and incompetent. The great object of his policy was the excitement of a crusade against the Turks, but he did not find the Christian princes responsive to his call. He died in 1458.

CALIXTUS, GEORGIUS (1586–1656), a celebrated Lutheran divine, born at Middleburg in Holstein in 1586. After studying at Helmstadt, Jena, Giessen, Tübingen, and Heidelberg, he had an opportunity of travelling through France and England, where he became acquainted with the leading Reformers, and saw the different forms which the Reformed church had assumed. On his return he was appointed professor of divinity at Helmstadt by the duke of Brunswick, who had admired his abilities in a contest which he had when a young man with the Jesuit Augustine Turrianus. After becoming a master of arts he published a book, *Disputationes de Præcipuis Religionis Christianæ Capitibus*, which provoked the hostile criticism of several learned men; and on his elevation to the professorship he published his *Epitome of Theology*, and soon after his *Epitome of Moral Theology*, which gave so great offence as to induce Statius Buscher to charge him with a secret leaning to Romanism. Scarcely had he refuted the accusation of Buscher, when, on account of his intimacy with the Reformed divines at the conference of Thorn, and his desire to unite them with the Lutherans, a new charge was preferred against him, principally at the instance of Calovius, of a secret attachment to Calvinism. The disputes to which this gave rise, known in the church as the Syncretistic controversy, lasted during the whole lifetime of Calixtus, and distracted the Lutheran Church, till a new controversy arose with Spener and the Pietists of Halle. Calixtus died in 1656. There is a monograph on Calixtus by Henke, 2 vols. 1853–56; see also Dorner, *Gesch. d. Protest. Theol.*, pp. 606–624.

CALLAO, the chief port of Peru, lies 8½ miles from Lima, the capital city, in 12° 4′ S. lat., 77° 13′ W. long. It is built on a flat point of land in the recess of a spacious and well-sheltered bay, which is partly enclosed by the islands of San Lorenzo and Fronton, and affords the best anchorage on the Peruvian coast. The modern town lies half a mile north of the site of an older city, destroyed by an earthquake and invasion of the sea in 1746. It consists mainly of houses built of wicker-work and plastered with mud, stronger buildings being dangerous from the frequency of earthquakes; but a walled quadrangular fortress, built by the Spanish Government between 1770 and 1775, extends over about 15 acres, and is now used for the custom-house offices and stores. There are also several forts mounting cannon, and among the public buildings are the military and naval Government offices and barracks, three Catholic churches and a Protestant chapel, two clubs, a hospital, and four banks. Several newspapers are published in the town. Callao is the headquarters of the Pacific Steam Navigation Company in South America (incorporated in 1840), and the works in connection with their large fleet of steam-vessels—foundries, carpenters' shops, flour-mills, bakeries, and gas-works—occupy a large area near the custom-house. A large steam sugar-refinery is also in operation. Harbour works, consisting of sea walls of concrete blocks, and docks, with

berthing space for thirty large vessels, begun in 1871, were completed in February 1875, superseding the old and inconvenient pier and boat harbour. These works comprise also eighteen steam-cranes for loading goods, a triple line of railway along the dock walls, gas illumination, and supplies of fresh water. A floating dock, 300 feet in length, capable of taking up a vessel of 21 feet draught, and 5000 tons weight, was built in Glasgow and sent out to Callao harbour in 1863. The phenomenon of the bubbling up of sulphuretted hydrogen gas in the harbour, known as "Callao painter," from its action on the paint of ships, has generally been ascribed to volcanic action, the belief having been that Callao is in the crater of an extinct volcano; but the borings for the new works discovered the cause of this to be in strongly impregnated springs forcing their way up through a stratum of clay and mud. Callao communicates with Lima by carriage road, and by a railway, completed in 1852, which is now extended through the capital towards Oroya over the Maritime Andes. The Pacific Company despatches or receives an ocean steamer almost every week to or from Liverpool by Valparaiso, the Strait of Magellan, and Rio de Janeiro; a separate bi-weekly steam line unites the port with Valparaiso, and communication is maintained with Panama by steamers four times a month each way. French and German steam lines have also headquarters at Callao. Trade is carried on mainly with Britain, the United States, France, Italy, Germany, Norway, and Central America, an average of nearly 2000 vessels entering the harbour annually, and frequently clearing in ballast for the Guano Islands, although exportation from the former main source of supply of guano —the Chincha Islands—ceased in 1872. This substance continues to be the most valuable export; after it come sugar, cotton, wool, hides, silver, and gold. Callao imports timber and railway material, wheat, ice, cattle, coal, and mixed cargoes of manufactures from foreign countries, and considerable quantities of flour from Chili. The whole value of imports and exports exceeds £6,000,000 annually. Since 1850, with the exception of the years between 1856 and 1861, when the immigration was prohibited by Congress, Chinese coolies have been imported in considerable numbers through Callao from the Portuguese possession of Macao in China. Perhaps 100,000 male Chinese have been introduced under contracts to serve for eight years; the passages have too often been attended with great hardships and frightful mortality, but the Chinese prove valuable workers on the great railroads now constructing in Peru.

Though the climate of Callao is good, having the pure breeze from the Pacific, and a temperature rarely exceeding 77° or falling below 65° Fahr., yet, in the absence of all hygiene, diseases, such as fevers and smallpox, are very prevalent, and the rate of mortality is high. The population, in default of recent exact enumeration, may be taken at from 15,000 to 18,000; the census of 1866, the latest, gave 14,800, a decrease of upwards of 2000 in seven years, and the number was further reduced by the havoc made by yellow fever in 1868. The traffic and business, and with these probably the population, of the port are, however, increasing.

CALLCOTT, Sir Augustus Wall (1779-1844), Knt., R.A., one of the most distinguished of English landscape painters, was born at Kensington in 1779, and died there in 1844. His first study was music; and he sang for several years in the choir of Westminster Abbey. But at the age of twenty he had determined to give up music, and had exhibited his first painting at the Royal Academy. He gradually rose to distinction, and was elected an associate in 1807 and an academician in 1810. In 1827 he received the honour of knighthood; and, seven years later, was appointed surveyor of the royal pictures. His two principal subject pictures—Raphael and the Fornarina, and Milton dictating to his Daughters, are much inferior to his landscapes, which are placed in the highest class by their refined taste and quiet beauty. Callcott always chose to paint nature in her lovely and placid aspect; and has therefore been called the English Claude.

CALLCOTT, John Wall (1766-1821), brother of the preceding, was born at Kensington in 1766, and was the son of a builder. At the age of seven he was sent to a neighbouring day school, where he continued for five years, studying chiefly Latin and Greek. During this time he frequently went to Kensington church, in the repairs of which his father was employed, and the impression he received on hearing the organ of that church seems to have roused his love for music. The organist at that time was Henry Whitney, from whom Callcott received his first musical instruction. He did not, however, choose music as a profession, being desirous to become a surgeon, only when on witnessing a surgical operation he found his nervous system seriously affected by the sight, he determined to devote himself to music. His intimacy with Dr Arnold and other leading musicians of the day procured him access to artistic circles; and his successful competition for the prize offered by a musical society called the "Catch Club" soon spread his reputation as composer of glees, catches, canons, and other pieces of concerted vocal music. On these his reputation as a creative musician is mainly founded. In them he displays considerable skill and talent, and some of his glees retain their popularity at the present day. They are well adapted to the voice, and their melodies are pleasing and not without feeling. As an instrumental composer Callcott never succeeded, not even after he had taken lessons from Haydn. But of far greater importance than his compositions are his theoretical writings, and it is chiefly for the sake of the latter that he is noteworthy beyond other English composers of equal merit. His *Musical Grammar*, published in 1806 (3d edition, 1817), was long considered as the standard work of musical instruction in this country, and has not been superseded up to the present day by any other book produced by an English musician. It is a scholarly and lucid treatment of the rudiments of the art, but at present, of course, antiquated to a great extent, and, indeed, all but useless to the student of modern music. Callcott was a much esteemed teacher of music for many years. He also held the position of organist at various churches. In 1800 he took his degree of Mus. D. at Oxford, and in 1805 he succeeded Dr Crotch as musical lecturer at the Royal Institution. Towards the end of his life his artistic career was frequently interrupted by ill-health. He died, after much suffering, in 1821. A posthumous collection of his most favourite vocal pieces was published with a memoir of his life by his son-in-law, Mr W. Horsley, himself a composer of note. Numerous other works remain in manuscript.

CALLCOTT, Mrs Maria Graham (1786-1844), daughter of Admiral Dundas, became the wife of Sir Augustus Callcott in 1827. With her first husband, Capt. Graham, R.N., she travelled in India, South Africa, and South America, where she acted for some time as teacher of Donna Maria, who became queen of Portugal in 1826; and in the company of her second husband she spent much time in the south of Europe. She published accounts of her visits to India (1812), and to the environs of Rome (1820); *Memoirs of Poussin* (1820); a *History of France*; a *History of Spain* (1828); *Essays toward a History of Painting* (1836); *Little Arthur's History of England* (1836); and the *Scripture Herbal* (1842).

CALLIMACHUS, a celebrated Greek poet, was a native of Cyrene, and a descendant of the illustrious house of

the Battiadæ, whence by Ovid and others he is called Battiades. He flourished under Ptolemies Philadelphus and Euergetes, and probably succeeded Zenodotus as chief librarian of the famous Alexandrian library, an office he held from about 260 B.C. till his death, which took place about 240 B.C. He was regarded, according to Quintilian, as the prince of Greek elegiac poets. His style is elegant and nervous, yet his excellences are rather the result of excessive elaboration than of genuine poetic power: hence Ovid (*Am.*, i. 15) says of him—*Quamvis ingenio non valet, arte valet.* Perhaps the *Hymn to Apollo* should be excepted from this criticism. Callimachus was a learned critic and grammarian, and the instructor of Eratosthenes, Aristophanes of Byzantium, and Apollonius Rhodius. He wrote in prose and in verse on a great variety of subjects; but his only existing works are six hymns, seventy-three epigrams, and some fragments of elegies. Of the various imitations of Callimachus by the Roman poets, the small poem by Catullus, *De coma Berenices*, is the most celebrated.

Among the numerous editions of his works the following may be noticed:—By Grævius with Spanheim's Commentary, Utrecht, 1697; by Ernesti, Leyden, 1761; by Bloomfield, Lond., 1815; by Volzer, Lips. 1817; *Fragmenta*, by Næke, 1844; *Hymni et Epigrammata*, by Meineke, 1861; *Callimachea*, by Schneider,—i. (*Hymni*), 1870, ii., 1847.

CALLIMACHUS, an architect and statuary, the inventor of the Corinthian column, was probably a native of Corinth. He is said to have derived the idea of the Corinthian capital from observing an acanthus plant surrounding a tile-covered basket which had been placed over a tomb. His era is uncertain; but as the Corinthian column was used in 396 B.C., by Scopas, the architect of the temple of Athena Alea at Tegea, he must have lived before that time. Though Callimachus worked admirably in marble he is said to have spoiled his original conceptions by excessive elaboration, which rendered his style artificial. (Plin., *N. H.*, xxxiv. 8, s. 19.)

CALLIOPE, the muse of epic poetry. She was so named from the sweetness of her voice, and was the last of the nine sisters. Her distinguishing office was to record heroic actions; and she is represented with a tablet and style, or a roll of paper in her hand. See MUSES.

CALLIRRHOE, in Greek legend, was a daughter of the river god Achelous, and became the wife of Alcmæon, who had wandered from Argos to be purified in the water of the Achelous from the crime of having killed his mother Eriphyle. He had taken with him from Argos the ill-omened necklace and *peplos* of Harmonia, with which his mother had been misled by Polynices, but he had left them in Arcadia. Callirrhoe pressed so hard to obtain them that he was compelled to go for that purpose to Phegeus, the king of Psophis in Arcadia, with whom he had left them. While returning he was waylaid by Phegeus and killed. Callirrhoe now implored the gods to cause her two young sons to grow at once to manhood to avenge their father's death. This was granted, and her sons slew Phegeus with his two sons, and returning with the necklace and *peplos*, dedicated them at Delphi.

CALLISTHENES, a philosopher of Olynthus, and a relation and pupil of Aristotle, through whose recommendation he was appointed to attend Alexander in his Asiatic expedition, 334 B.C. He had the imprudence to censure the conqueror's adoption of Oriental customs, inveighing especially against the servile ceremony of adoration. Having by the boldness of his censures rendered himself highly obnoxious to the king, he was accused of being privy to a treasonable conspiracy; and after being kept in chains for seven months he died, either by torture, or of a disease arising from excessive obesity. Callisthenes wrote an account of Alexander's expedition, a history of Greece, and other works, all of which have perished.

CALLISTO, in Greek Mythology, an Arcadian nymph, who was transformed into a bear as a penalty for having born to Zeus a son, Arcas, from whom the Arcadians, or bear-people, derived their name (Ovid, *Metam.*, ii. 468, *fol.*) Arcas, when hunting, encountered the bear Callisto, and would have shot her, had not Zeus with swift wind carried up both to the skies, where he placed them as a constellation. Artemis, as goddess of hunting, was styled Callisto in Arcadia, and had the symbol of a bear.

CALLISTRATUS, an Athenian orator, whose eloquence made such an impression on Demosthenes that he resolved to devote himself to oratory. On account of the surrender of Oropus to the Thebans Callistratus, despite his magnificent defence, was condemned to death, 361 B.C. He fled to Methone in Macedonia, where it is said he founded the city of Datum, afterwards Philippi. Having returned to Athens, he was put to death.

CALLISTRATUS, an Athenian poet, whose works have nearly all perished. He is now only known as the author of the hymn in honour of Harmodius and Aristogiton, who fell in their attempt to put down the dynasty of the Pisistratidæ at Athens. This ode, which is contained in Athenæus, has been beautifully translated by Thomas Moore.

CALLOT, JACQUES (1593–1635), a French engraver, was born in 1593 at Nancy in Lorraine, where his father was a herald at arms. He early discovered a very strong predilection for art, and at the age of twelve quitted home without his father's consent, and set out for Rome, where he intended to prosecute his studies. Being utterly destitute of funds he joined a troop of Bohemians, and arrived in their company at Florence. In this city he had the good fortune to attract the notice of a gentleman of the court, who supplied him with the means of study; but he removed in a short time to Rome, where, however, he was recognized by some relatives, who immediately compelled him to return home. Two years after this, and when only fourteen years old, he again left France contrary to the wishes of his friends, and reached Turin before he was overtaken by his elder brother, who had been despatched in quest of him. As his enthusiasm for art remained undiminished after these disappointments, he was at last allowed to accompany the duke of Lorraine's envoy to the Papal court. His first care was to study the art of design, of which in a short time he became a perfect master. Philip Thomasin instructed him in the use of the graver, which, however, he ultimately abandoned, substituting the point as better adapted for his purposes. From Rome he went to Florence, where he remained till the death of Cosmo II., the Mæcenas of these times. On returning to his native country he was warmly received by the then duke of Lorraine, who admired and encouraged him. As his fame was now spread abroad in various countries of Europe, many distinguished persons gave him commissions to execute. By the Infanta Isabella, sovereign of the Low Countries, he was commissioned to engrave a design of the siege of Breda; and at the request of Louis XIII. he designed the siege of Rochelle, and the attack on the Isle of Ré. When, however, in 1631, he was desired by that monarch to execute an engraving of the siege of Nancy, which he had just taken, Callot refused, saying, "I would rather cut off my thumb than do anything against the honour of my prince and of my country;" to which Louis replied—that the duke of Lorraine was happy in possessing such subjects as Callot. Shortly after this he returned to his native place, from which the king failed to allure him with the offer of a handsome pension. He died in 1635 at the age of forty-two. He engraved in all about 1600 pieces,

the best of which are those executed in aquafortis. No one ever possessed in a higher degree the talent for grouping a large number of figures in a small space, and of representing with two or three bold strokes the expression, action, and peculiar features of each individual. Freedom, variety, and *naïveté* characterize all his pieces. His Fairs, his Miseries of War, his Sieges, his Temptation of St Anthony, and his Conversion of St Paul will be sought after and admired as long as there are artists to learn and a public to appreciate.

CALMAR, or KALMAR, the capital of a province of the same name in Sweden, on Calmar Sound opposite the island of Öland, about 190 miles from Stockholm, in 56° 40′ N. lat., 16° 20′ E. long. It is built on the island of Quarnholm, and communicates with the suburbs on the mainland by a bridge of boats. Most of the houses are built of wood; but the cathedral, erected in the 17th century by Nicodemus Tessin the younger, the castle, the town-house, and other public edifices are of stone, of which there are good quarries in the island of Öland. It has a gymnasium, and several smaller educational establishments. The harbour is safe and commodious, but a large part of the trade has been transferred to Stockholm. Besides its manufactures of woollen stuffs, leather, tobacco, and potash, the town carries on shipbuilding and an export trade in flax, timber, iron, alum, pitch, &c. Calmar was once a flourishing and strongly-fortified town; and, previous to the conflagration of 1647, was built on the mainland. It is frequently mentioned both in the military and political annals of Sweden, and especially gives name to the treaty by which Sweden, Denmark, and Norway were, in 1397, erected into one kingdom under Queen Margaret. Population in 1868, 9420.

CALMET, DOM AUGUSTINE (1672–1757), a scholar and Biblical critic, born at Mesnil-la-Horgne in Lorraine, in 1672. In his fifteenth year he went to the university of Pont-a-Mousson, which he attended for a single session. In 1688 he joined the Benedictines at the abbey of St Mansin, into whose order he was publicly received in the following year. His theological and philosophical studies he completed at the abbey of Munster, to which he was sent in 1704 with the rank of sub-prior. He here organized an academy of eight or ten monks, the sole business of whose life was to assist him in preparing his *Commentary on the Bible*. The publication of this voluminous work, begun in 1707, was not completed till 1716. Two years after this latter date he was rewarded for his services with a presentation to the abbey of St Leopold at Nancy, and ten years after to that of Sénones, where he died in 1757. His attachment to his country and congregation was such, that he refused a bishopric *in partibus* offered to him by Pope Benedict XIII. Besides his *Commentary*, he wrote many other works, of which the most important are his *Histoire de l'Ancien et du Nouveau Testament*, an introduction to the *Ecclesiastical History of Fleury*; *Dictionnaire historique, critique, et chronologique de la Bible*, an extremely learned, but by no means judicious work; and *Histoire universelle sacrée et profane*, 15 vols. 4to. The *Dictionary of the Bible* has been translated into English, and is a well-known work.

CALMUCKS, KALMUCKS, or KALMUIKS, a people of Mongolian race who inhabit various parts of the Russian and Chinese empires, as well as other portions of Central Asia. They are of the middle height, fairly proportioned, and of considerable strength; their cheek-bones are prominent, the chin short, the nose turned up, the beard thin, and the hair scrubby. For the most part still in the nomadic stage, they inhabit conical felt tents, which they set up in regular lines like the streets of a town. Their wealth consists entirely in small but high-spirited horses, excellent cattle, and broad-tailed, rough-fleeced sheep. They are so much addicted to gaming that they not unfrequently stake everything they possess. In religion they are adherents of Lamaism, and their conduct is greatly under the control of their priests. Their language is closely connected with Mongolian proper, and is written with a similar alphabet; its grammar and vocabulary have been made known to Europeans more especially by A. H. Zwick about 1853. Of their literature the great proportion is religious, and is derived from Indian originals. The *Siddhi Kür*, a collection of stories, which is one of their most famous productions, was published with a German translation, a glossary, and notes, by B. Jülg, at Leipsic in 1866. As early as the 16th century the Calmucks possessed an extensive district of Central Asia between the Altai mountains and the Thian Shan, and between the desert of Gobi and the Balkash or Tengis Lake; and they were also settled in what is now the southern part of the Yeniseisk government, where indeed they were first met by Russian emigrants. At that time they bore the name of Derben Oirat, or Four Confederates, being divided into the four tribes of Jungars, Turguts, Khoshots, and Durbots. In the 17th century the Calmucks grew extremely strong, and after violent feuds united themselves, under the leadership of Batur and his son Galdan, into the powerful Jungarian kingdom. The strife which preceded the unification occasioned important movements of some Calmuck bands towards the E. and S.E. of Russia. Under Kourliuk, the great mass of the Turguts appeared for the first time within the Russian territory on the eastern side of the Volga in 1630. They conquered the nomadic Nogais of the district, but on this first occasion turned back to the Kirghiz steppes. In 1636 as many as 50,000 *kibitkas* or more than 200,000 men and women crossed the Emba, and took possession of the Trans-Volga steppes of the present Astrakhan government; and plundering incursions began to be made on the Russian settlements, in Saratoff, Penza, and Tamboff, while Tobolsk, in Siberia, had to defend itself with arms in 1646. After the fall of Kourliuk, in an attack on Astrakhan itself, the Calmucks became less aggressive, and in 1655 passed of their own accord under Russian authority. Down to the middle of the 18th century bands, however, continued to arrive, and the depredations on Russian ground did not cease during all the long reign of the Khan Ayuka (1670–1724). This chief more than once broke his oath to the Russian Government; but he also on several occasions supplied very important contingents to the imperial army. His power is shown by the fact that his court was visited in 1713 by an ambassador from China. In the reign of the Empress Catharine the Russian Government created great discontent among the Calmucks by their general treatment, and still more by refusing to confirm Ubashi, the grandson of Ayuka, in his dignities. A Calmuck chieftain from Jungaria skilfully took advantage of this condition of affairs to persuade Ubashi and his subjects to return to Jungaria, and attempt its conquest. The result was the wonderful and disastrous flight of the Calmucks from Russia in 1771, so graphically described by De Quincey. The number of the fugitives amounted, according to some authorities, to 120,000. Harassed on all sides by savage troops of Cossacks and Khirghises, the wretched Calmucks pursued their way across the barren steppes, and their main body was routed in a terrible battle on the shores of the Balkash. The remnants were settled on the banks of the Ili by the Chinese emperor Kien Long, and there their descendants are still to be found. There still remained in Russia the Durbots, who were living in the Don territory, and those of the Astrakhan Calmucks who at the time of the flight happened to be on the right bank of the Volga.

The total number now in the Russian empire may be estimated at 120,000. In the Chinese territory, where they are known as Eliots, or Olüts, their numbers are considerable, but are not precisely known.

Altai*, 1838, Quatremère, "Observ. géogr. et hist. sur les Calmouks," in *Journ. des Savants*, 1839; Hommaire de Hell, *Les steppes de la mer Caspienne*, 1843; Tchihatcheff, *Voyage d'Altai*, 1846; Semenoff, *Slovar Ross. Imp.*

CALNE, a town of England, in the county of Wiltshire, connected with the Great Western railway system by a branch line opened in 1863, and situated about 16 miles directly east of Bath. It stands in a valley intersected by the little brook of Calne, and is surrounded by the high table-land of Marlborough Downs and Salisbury Plain. The town is clean and well paved, and contains an ancient church (St Mark's) with a tower by Inigo Jones, and a town-house considerably enlarged by the marquis of Lansdowne, whose seat of Bowood is about two miles distant. The educational establishments include Bentley's grammar school founded in 1660, national and infant schools, and an institution for training female servants, which was endowed by Mrs Guthrie, to whom the town is also indebted for a children's hospital. The principal trade of Calne is the curing of bacon; and there are also flax-mills, paper-mills, and flour-mills in operation. The manufacture of broad cloth, at one time of great importance, is almost extinct. Calne formerly returned two members to parliament, but the number is now reduced to one. Population of the municipal borough in 1871, 2468, and of the parliamentary, 5315. From the remains found in the vicinity, Calne seems to have been an important Roman station. It was the occasional residence of the West Saxon kings; and is celebrated in legendary ecclesiastical history for the escape of Dunstan at the synod held there in 997.

CALOMEL, mercurous chloride, or subchloride of mercury (HgCl), is a compound of mercury of great value in medicine. It occurs native as horn quicksilver in the mercury mines of Idria, at Obermoschel, in Bavaria, Horowitz in Bohemia, and Almaden in Spain, in the form of translucent tetragonal crystals, with an adamantine lustre, and a dirty white grey or brownish colour.

A great number of processes are available for the preparation of calomel for pharmaceutical purposes. The directions of the *British Pharmacopœia* are as follows:—Sulphate of mercury 10 oz., mercury 7 oz., common salt 5 oz., and boiling distilled water. The sulphate of mercury is to be moistened with part of the water, and it and the mercury rubbed up together until all metallic globules disappear. The salt is then added, and the whole thoroughly triturated, after which it is sublimed in a vessel of such capacity that the calomel, instead of forming a crystalline crust on the sides as it would do in a vessel of small dimensions, shall fall in the form of a fine impalpable powder on the floor of the receiver. The sublimate is to be washed until the washings cease to be darkened on the addition of a drop of sulphide of ammonium. The reaction in the above case may be represented thus:

$$HgSO_4 + Hg + 2NaCl = Na_2SO_4 + 2HgCl\,.$$

After thorough washing the calomel has to be dried at a temperature not exceeding 212° Fahr., and preserved in a jar away from the light, exposure to which darkens it by partial decomposition into corrosive sublimate $HgCl_2$ and metallic mercury. Calomel when so prepared is a dull, heavy, white, nearly tasteless powder, which is rendered yellowish by trituration in a mortar or when heated. It is entirely insoluble in water, alcohol, or ether, and volatilizes, below a red heat, without fusion. When sublimed in a confined chamber it forms a crust or cake, the inner surface of which is covered with crystals in fine quadrangular prisms, having a transparent dirty-white appearance.

Calomel is one of the mildest and most frequently employed of all mercurial preparations, producing its effects with little local irritation. It exercises a powerful influence on the secreting organs, stimulating the liver and intestinal glands to increased activity, on which account it is much relied on in cases of functional derangement of the liver. It is usually combined with other remedial agents, each exercising an influence in modifying the effect or increasing the activity of the other. Thus as a purgative it is combined with jalap, scammony, colocynth, and other similar substances. The much used Plummer's pill, which is essentially the same as the compound calomel pill of the *British Pharmacopœia*, contains in addition to calomel an equal weight of oxysulphide of antimony, with guaiacum and castor oil. It is employed both in Europe and America as an alterative in chronic skin diseases, in liver affections, and in disorders of the digestive system. On account of its tastelessness calomel is a convenient aperient for children, who however appear to be less susceptible to its effects than adults. It has been used in very large doses in the treatment of cholera; and it is a convenient medium for producing salivation. Suspended in gum or glycerine water it has been used for hypodermic injection; and in the form of an ointment it is one of the most useful of external applications in the case of obstinate skin diseases.

CALONNE, Charles Alexandre de (1734–1802), a French statesman, was born at Douai in 1734. He was descended from a good family and entered the profession of the law, in which he rapidly attained success. He became in succession advocate to the general council of Artois, *procureur* to the parliament of Douai, and finally master of requests, a dignity which gave him the right of sitting in the general council. He seems to have been a man of great business capacity, gay and careless in temperament, and thoroughly unscrupulous in political action. In the terrible crisis of affairs preceding the French Revolution, when minister after minister tried in vain to replenish the exhausted royal treasury and was dismissed for want of success, Calonne was summoned to take the general control of affairs. He assumed office in 1783, and at first everything seemed to prosper. Money flowed in readily, and the gaiety of the minister gave courage to the court. But his prosperity was hollow and rested on no secure foundation. Calonne had levied taxes until it was impossible to extract more from the impoverished people. He had borrowed till his credit was entirely gone, and he at last found himself compelled to disclose to the king the true state of affairs, and to lay before him what in his opinion was the only measure that could restore France. The first step in this proposed plan was the convocation of the notables, and the writs summoning them were issued in December 1786. On the 22d February of the following year Calonne disclosed to the notables his anxiously expected scheme for reconstituting the finances. The main provisions of this plan were the redistribution of the taxes, so that the whole might not fall on the unprivileged classes, the imposition of a land tax on the revenues of the nobles, and of a similar tax on the incomes of the clergy, and the abolition of *corvées* and the *gabelle*. All Calonne's eloquence could not succeed in rendering this scheme palatable either to the notables or to the people. The noblesse and clergy strenuously resisted any attempt to infringe upon their privileges, and the people were beginning to feel that in a convocation assembled to settle the affairs of France the nation itself had no part. Calonne had opened the floodgates, and was powerless to resist the torrent. His fall, however, was primarily due to the

indignation of the court. He was dismissed from office in April, and exiled to Lorraine. Soon afterwards he passed over to England, and during his residence there kept up a polemical correspondence with Necker on the finances. In 1789, when the States-General were about to assemble, he crossed over to Flanders in the hope of being allowed to offer himself for election, but he was sternly forbidden to enter France. In revenge he joined the Bourbon party at Coblentz, wrote in their favour, and expended nearly all the fortune brought him by his wife, a wealthy widow. In 1802, having again taken up his abode in London, he received permission from Napoleon to return to France. He died 30th October 1802, about a month after his arrival in his native country. Calonne was the author of several works on the financial and political condition of France during the period of the Revolution, which are still of value.

CALPURNIUS, Titus, a Roman bucolic poet, under whose name eleven eclogues have been transmitted to us, is interesting as the first imitator of Virgil in pastoral poetry, and from the controversy respecting his date. His eclogues usually occur in MS. along with the *Cynegeticon* of Nemesianus, who undoubtedly flourished under Carinus (284 A.D.), and hence he has been generally referred to the same epoch. This view is expressed in a famous passage of Gibbon (ch. xii.), where Calpurnius is cited as an authority for the spectacles exhibited with unusual splendour by Carinus. Gustavus Sarpe, in an ingenious disquisition published in 1819, first maintained that Calpurnius had lived as early as the reign of Nero; his arguments have been repeated and greatly fortified by Moritz Haupt (1854), and have convinced the most recent authorities, Teuffel, the latest and most accurate historian of Latin literature, and Mr Pinder. This thesis would indeed be untenable if the last four eclogues could be ascribed to Calpurnius, as they contain manifest imitations of Statius. Haupt, however, seems to have proved from internal evidence that they are the work of Nemesianus. Upon attentive consideration, however, it appears to the present writer that Calpurnius cannot have written either under Nero or under Carinus. 1. The first eclogue is indirectly dedicated to a sovereign, complimented as the auspicious successor of a lawless tyrant, by whom a large proportion of the senate had been executed or imprisoned (ver. 60–62, 69–73). This censure is inapplicable to Carus, and the compliment could in no case have been addressed to his son and successor Carinus. It is almost equally inappropriate to Nero's predecessor, Claudius, who was popular with the senate (Suet. *in Claudio*, 12, 46). 2. The accession of the new emperor is hailed as the termination of war (*Ecl.* i. ver. 46–50) and the harbinger of a durable peace (i. 54; iv. 127, 131, and other passages). But Nero's accession took place at a period of profound peace, and Carinus's at one of extensive foreign hostilities. 3. Carinus cannot have been intended, inasmuch as no mention is made of his own or his father's military renown or of the association of his brother in the empire; nor can he have been represented as favourable to the senate, which he notoriously detested (Vopiscus *in Carino*, c. 17). If, on the other hand, the poet had written to celebrate the accession of Nero, he would not have omitted to celebrate the then omnipotent Agrippina. 4. Calpurnius's description of the games in the amphitheatre (*Ecl.* 7) differs from the account of Vopiscus in the Augustan history,—whatever is especially celebrated by the one being omitted by the other. Calpurnius dwells wholly on the zoological, Vopiscus on the musical and dramatic features of the entertainment; the former has not a word to say on the *nova spectacula* indicated by the latter as the distinguishing features of the show—the thousand pantomimists, the four hundred performers on wind instruments, the [illegible] *agentes*. It may also be remarked that Calpu[illegible] of the amphitheatre as looking down upon th[illegible] rock, which, according to the preferable opini[illegible] the opposite side of the Capitoline hill to th[illegible] Martius, where the games were exhibited by N[illegible] *in Nerone*, 12).

It remains, therefore, to discover an emperor to the panegyric of Calpurnius can apply, whose pred[illegible] should have been a scourge to his subjects in gen[illegible] to the senate in particular, and whose own accession early age should have been hailed as a pledge of p[illegible] tranquillity—one, moreover, who should have exhi[illegible] public spectacles in the amphitheatre. All these cond[illegible] are fulfilled by Gordian III., whose accession at the of thirteen or sixteen (238 A.D.) closed a series of civil [illegible] and revolts which had proved fatal to six emperors, w[illegible] the character of Maximin, virtually his immediate [illegible] cessor, entirely corresponds to the description of [illegible] purnius. Maximin's ferocity had been chiefly indulged the expense of the senate (Capitolinus, *passim*), and [illegible] public relief at Gordian's accession is significantly expr[illegible] by the great preponderance of inscriptions celebrating tranquillity, of which he was regarded as the harbing[illegible] among the legends of the medals struck during his reig[illegible] Other medals attest the fact of his having exhibited wi[illegible] beasts in the Flavian amphitheatre (Gori, vol. iii. p 115–121). It may be added that the imperial favouri[illegible] upon whose patronage Calpurnius relies may be plausib[illegible] identified with Timesitheus, Gordian's virtuous minister a[illegible] father-in-law; and that the mention (*Ecl.* i. 77–78) of t[illegible] comet which signalized the succession of the prince [illegible] illustrated by the appearance of a comet in China, whi[illegible] would probably be visible in Italy, in September 238, thr[illegible] months after Gordian's proclamation as sole emper[illegible] (Williams, *Chinese Observations of Comets*, p. 21.) Th[illegible] comet continued visible in China for forty-one da[illegible] Calpurnius's statement that it had been conspicuous f[illegible] twenty days when he wrote enables us, if our hypothe[illegible] be correct, to indicate the date of his literary *début* wi[illegible] remarkable precision.

In this case Calpurnius is not strictly entitled to th[illegible] distinction of having led the way in the bucolic imitation of Virgil,—fragments of two anonymous eclogues having been recently discovered and published which undoubtedly belong to the age of Nero. He is, however, Virgil's first follower of any mark, and no important modification has been introduced into his treatment. He is unquestionably a skilful literary craftsman, a fair scholar and an apt courtier, and not devoid of real poetical feeling. The bastard style of pastoral cultivated by him, in which the description of nature is made the writer's pretext, while ingenious flattery is his real purpose, nevertheless excludes genuine pleasure, and consequently genuine poetical achievement. He may be fairly compared to the minor poets of the reign of Anne. No biographical particulars respecting him are known except his complaints of his poverty.

Calpurnius was first printed in 1471, together with Silius Italicus. He has been frequently republished, generally in company with Gratius and Nemesianus. The best edition is in vol. ii. of Wernsdorf's *Poetæ Latini Minores*. The most recent is that by Glaeser, Göttingen, 1842. (R. G.)

CALTAGIRONE, or Calatagirone, a town of Sicily, the seat of a bishop, in the province of Catania, and about 34 miles S.W. of the city of that name, is situated on two rocky eminences united by a bridge, about 2170 feet above the level of the sea. It is well built and possesses a fine market-place, the ruins of a castle, a cathedral, several churches, and ten convents, a *casa communale* or town-house, built on ancient substructions, an orphanage, and a

total nu[illegible] Its inhabitants are said to have a much greater [illegible]d at 1[illegible] of culture than is common in the provincial towns knowi[illegible]ly, and great encouragement is given by the higher , but[illegible]s to the cause of education. The most remarkable [illegible]stry in the town is the manufacture of *terra-cotta* [illegible]es, representing different types of Italian costume. [illegible]e remains of an aqueduct, an ancient subterranean road [illegible]it out of the rock, and various mosaics and other [a]ntiquities discovered by excavation, show that the site of [t]he town was already occupied at a very early date; and [a]ccording to some an identification may be effected with [H]ybla Minor. The present city, however, owes its origin [t]o the Saracens, who defeated the Greeks there in 831, and [r]emained in possession till 1060.. Population, 25,978.

CALTANISETTA, or CALATANISETTA, the capital of a [p]rovince of the same name in Sicily, is situated in an [e]xtensive and fertile plain, dominated by Monte San [G]iuliano, near the right bank of the Salso, 62 miles S.E. [o]f Palermo. It is well built, and contains several handsome [e]difices, is defended by a castle, and is the seat of judicial [c]ourts. In the neighbourhood, at Terra-Pilata, are several [s]prings emitting hydrogen gas, a mud-volcano, and extensive [s]ulphur-works; and about 2 miles distant is the Abbey of [S]anto Spirito, founded by Roger I., where a great national [fe]stival is held every Whitmonday. The town is of [S]aracenic origin, as indeed its name suggests—Kalat-al-Nisa, [t]he Ladies' Castle; but it has been completely modernized. [I]n 1820 the people of Palermo were defeated near it by the [N]eapolitan General Pepe. Population, 26,156.

CALVADOS, a department in the north of France, [e]xtending from 48° 46′ to 49° 25′ N. lat., and from 0° 26′ [E]. to 1° 10′ W. long., formed out of that part of Lower [N]ormandy which comprised Bessin, Bocage, the Champagne [d]e Caen, Auge, and the western part of Lieuvin. It is [s]aid to have received its name from a ledge of rocks, [s]tretching along the coast for a distance of about 15 miles [b]etween the mouths of the rivers Orne and Vire, on [w]hich the *Calvados*, a vessel of the Spanish Armada, was [w]recked in 1588. It is bounded N. by the English [C]hannel, E. by the department of Eure, S. by that of [O]rne, W. by that of Manche, and has an area of 2132 [s]quare miles. The southern part of the department is [s]omewhat elevated, being crossed by a mountain range, and [f]orms a continuation of the great water-shed between the [b]asins of the Seine and Loire; but the rest of the surface [i]s gently undulating, and consists of extensive valleys [w]atered by numerous streams which fall into the English [C]hannel. The coast is high, and generally inaccessible, [e]xcept at the mouths of the principal rivers, such as the [T]ouques, the Dives, the Orne, and the Vire, which are [n]avigable at high tide for several miles inland, and are [i]ndicated by lighthouses at their mouths. The valleys, [w]hich generally slope in a direction from south to north, [a]fford abundant pasturage for horses and cattle, and the [a]griculture of the district is superior to that of most of the [o]ther departments. Wheat, potatoes, and all kinds of [v]egetables are raised in great quantities for the markets [o]f the interior and for exportation. The orchards of the [A]uge district produce a very superior kind of cider, of [w]hich upwards of 30,000,000 gallons are made in the [d]epartment; while Isigny is the centre of a large domestic [a]nd export trade in butter, cheese, and other dairy produce. [P]oultry is reared to a considerable extent for the Paris [m]arket. In the larger towns, of which on account of the [a]gricultural pursuits of the inhabitants there are very few, [t]here are manufactories of lace, woollen yarn and cloth, [l]inen, calicoes, flannel, shawls, cutlery, and earthenware. [B]esides these the paper-mills, oil-mills, tanneries, refineries [o]f beet-root and foreign sugar, distilleries, and bleach-fields, [s]cattered throughout the department, give employment to a great number of hands. Although seams of coal are found and wrought at Ligny, most of the coal used in the department is imported from England or Belgium. Building stone and fuller's earth are plentiful. The fisheries along the coast are extensively prosecuted for Parisian consumpt, and consist chiefly of lobster, oyster, herring, and mackerel fishing. There is a canal from Caen to Ouistreham. A line of railway from Paris to Cherbourg runs through the country and gives off five branches. The department is divided into six arrondissements,—Caen, Falaise, Bayeux, Vire, Lisieux, and Pont l'Evêque, the chief towns of which bear the same name. The principal port is Honfleur. The population in 1872 was 454,012.

CALVART, DENIS (1555-1619), a Flemish painter, born at Antwerp in 1555. After studying landscape-painting for some time in his native city he went to Bologna, where he perfected himself in the anatomy of the human form under Prospero Fontana, and so completely lost the mannerism of Flemish art that his paintings appear to be the work of an Italian. From Bologna he went to Rome, where he assisted Sabbatini in his works for the Papal palace, and devoted much of his time to copying and studying the works of Raffaelle. He ultimately returned to Bologna, and founded a school, of which the greatest ornaments are Guido and Domenichino. His works are especially admired for the power of grouping and colouring which they display. He died at Bologna in 1619

CALVERT, GEORGE, LORD BALTIMORE (1582-1632), one of the principal secretaries of state under James I., was born at Kipling in Yorkshire in 1582. He was educated at Oxford, and after travelling on the Continent entered public service as secretary to Robert Cecil, afterwards earl of Salisbury. In 1617 he was knighted, and in 1619 he was made one of the principal secretaries of state. He retained office for five years, at the end of which term he resigned, alleging as a reason that he had recently adopted the Catholic faith. He still continued at court, however, in the capacity of a privy-councillor. In 1625 he was made Baron Baltimore, in the county of Longford, Ireland, and among other rewards he received for his services was a patent as lord of the province of Avalon in Newfoundland. As this colony was much exposed to the attacks of the French he left it, and obtained another patent for Maryland, in the north of Virginia. He died in 1632 before the grant was confirmed, but in that year it was made out in the name of his son Cecil. The city of Baltimore derives its name from the title of this family.

CALVI, a fortified town in Corsica, the capital of an arrondissement, is situated on a peninsula in the bay to which it gives its name, 38 miles W.S.W. of Bastia, in 42° 34′ 7″ N. lat. and 8° 45′ 10″ E. long. Its position is unsheltered, and its ancient fortifications present a mournful appearance, while its climate is rendered unhealthy by the exhalations from the neighbouring lagoon. Since the foundation of Ile Rousse by Paoli it has greatly decayed, and its interest is now mainly historical or antiquarian. The most important buildings are the old palace of the Genoese governor and the church with the monuments of the Baglioni family. Calvi was founded in the 13th century by Giovanniello of Pietra Allerata, one of the military adventurers of that restless period. In 1278 it passed into the hands of the Genoese, and from that date it was remarkable for its adherence to their side. It was attacked by De Thermes in 1553, and two years after it stood no fewer than three sieges with such determined resistance that the Genoese senate caused *Civitas Calvi semper fidelis* to be carved on the chief gate of the city, which still preserves the proud inscription. In 1794 Calvi was captured by the English, but it was retaken by the Corsicans in the following year. Population in 1872, 2164.

CALVIN, John (1509–1564), was born at Noyon, in Picardy, July 10, 1509. His father, Gerard Calvin or Cauvin,[1] was a notary-apostolic and procurator-fiscal for the lordship of Noyon, besides holding certain ecclesiastical offices in connection with that diocese. The name of his mother was Jeanne Lefranc; she was the daughter of an innkeeper at Cambray, who afterwards came to reside at Noyon. Gerard Calvin is described as a man of considerable sagacity and prudence, and on this account held in esteem by the leading men of the district. His wife added to considerable personal attractions the graces of a vivid and earnest piety. Their family consisted of four sons, of whom John was the second, and two daughters.

Of Calvin's early years only a few notices remain. His father destined him from the first for theological studies, being moved to this by the evidences afforded in his boyhood of a religious tendency, and perhaps also by a shrewd apprehension of the kind of pursuits in which he was most fitted to excel. The esteem in which the father was held opened for the boy a place in the household of the noble family of De Montmor, where he received his elementary education along with the children of the house, though at his father's expense. In his thirteenth year his father, whose circumstances were not affluent, procured for him from the bishop the office of chaplain in the Chapelle de Nôtre Dame de la Gesine. A few days after his appointment he received the tonsure, and on the 29th of May 1521 he was installed in his office. The plague having visited Noyon, the young De Montmors were sent to Paris to pursue their studies there, and thither Calvin accompanied them, being enabled by the income received from his benefice to meet the expense of a residence in the metropolis. His first school was the Collége de la Marche, at that time under the regency of Maturin Cordier, a man of excellent character, of sound learning, and of high repute as a teacher. To him Calvin ever acknowledged himself indebted for the benefits received under his tuition. In dedicating to him his Commentary on the First Epistle to the Thessalonians, as "eximiæ pietatis et doctrinæ viro," he declares that so had he been aided by his instruction that whatever subsequent progress he had made he only regarded as received from him, and "this," he adds, "I wish to testify to posterity that if any utility accrue to any from my writings they may acknowledge it as having in part flowed from thee." From this institution he removed to the Collége Montaigu, where he had for instructor a Spaniard, who is described as a man of learning, and to whom Calvin was indebted for the culture of his already acute intellect, by the study of dialectics and the scholastic philosophy. Whilst at school the future reformer distinguished himself by his superior abilities, and his indefatigable assiduity. He speedily outstripped all his competitors in grammatical studies, and by his skill and acumen as a student of philosophy, gave fruitful promise of that consummate excellence as a reasoner, in the department of speculative truth, which he afterwards displayed. Intensely devoted to study he cared little for the pastimes in which his fellow scholars indulged; he shunned society, and was more disposed to censure the frivolities of those around him than to seek the solace of their companionship; severe to others he was still more so to himself, and his pale face and attenuated frame bore witness at once to the rigour of his abstinence and the ardour with which he prosecuted his studies. In his nineteenth year he, through the influence of his father, obtained the living of Marteville, to which he was presented on the 27th of September 1527. After holding this preferment for nearly two years, he exchanged it in July 1529 for the cure of Pont l'Evêque, a village near to Noyon, and the place to which his father originally belonged. He appears to have been not a little elated by his early promotion, and although not ordained, he preached several sermons to the people. But though the career of ecclesiastical preferment was thus early opened to him, Calvin was destined not to become a priest of the Church of Rome. A change came over the mind both of his father and himself respecting his future career. Gerard Calvin, looking at things only from a worldly point of view, began to suspect that he had not chosen the most lucrative profession for his son, and that the law offered to a youth of his talents and industry a more promising sphere.[2] His son, on the other hand, had come under an influence of a very different kind, but which, with still more decisive impulse, inclined him to relinquish the ecclesiastical life. Through the counsels of his relation, Pierre Robert Olivetan, the first translator of the Bible into French, he had been led for the first time to study the sacred volume, and to test his religious opinions and practices by its dictates. The result was that, though not yet detached from the faith of the Romish church, he was very willing to relinquish all thoughts of becoming a priest in that communion. He accordingly readily complied with his father's suggestion; and having resigned his cure, he removed from Paris to Orleans, in order to study law under Pierre de l'Etoile, a distinguished jurisconsult, and at that time professor there. On this new pursuit Calvin entered with characteristic ardour, and such was his progress in legal knowledge, that he frequently occupied the chair of the professor, while his general reputation for ability and scholarship stood so high that, on leaving Orleans, he received the grade of doctor without payment of the usual fees, as a compliment to his merits. Other studies, however, besides those of law had occupied him whilst in this city. God, who had destined him for a very different career, was in His providence preparing him for the work he had to do. His mind, at first hardened by the influence of early superstition, was, he himself tells us, brought by sudden conversion into a state of docility.[3] An ardent desire to attain proficiency in sacred knowledge took possession of him, and though this did not lead him to renounce other studies, it rendered him frigid in the pursuit of them. At all times, indeed, a diligent student, he seems at this time to have been impelled by his zeal beyond those bounds which a wise regard to health would impose. It was his wont, after a frugal supper, to labour till midnight, and in the morning when he awoke, he would, before he arose, recall and digest what he had read the previous day, so as to make it thoroughly his own. "By these protracted vigils," says Beza, "he secured indeed a solid erudition, and an excellent memory; but it is probable he at the same time sowed the seeds of that disease which occasioned him various illnesses in after life, and at last brought upon him premature death."[4]

From Orleans Calvin went to Bourges to prosecute his studies under a learned Italian of the name of Alciati, whom Francis I. had invited into France, and settled as a professor of law in that university. Here he became acquainted with Melchior Volmar, a German, then professor of Greek at Bourges, and a man of sound erudition

[1] The family name of Calvin seems to have been written indifferently Cauvin, Chauve, Chauvin, Calvus, Calvinus. In the contemporary notices of Gerard and his family, in the capitular registers of the cathedral at Noyon, the name is always spelt Cauuin. The anagram of Calvin is Alcuin, and this in its Latinized form Alcuinus appears in two editions of his *Institutio* as that of the author (Audin, *Vie de Calvin*, i. 520). The syndics of Geneva address him in a letter written in 1540, and still preserved, as "Docteur Caulvin." In his letters written in French he usually signs himself "Jean Calvin." He affected the title of "Maitre," for what reason is not known.

[2] Calv., *Præf. ad Comment. in Psalmos.*

as well as exemplary character. By him Calvin was taught Greek, and introduced to the study of the New Testament in its original language, a service which he gratefully acknowledges in one of his printed works.[1] The conversation of Volmar also seems to have been of use to him in deepening his religious convictions, and confirming him in his attachment to the doctrines of the Reformation. These were now beginning to be widely diffused through France. Twelve years had elapsed since Luther had published his theses against indulgences,—twelve years of intense excitement and anxious discussion, not in Germany only, but in almost all the adjacent kingdoms In France there had not been as yet any overt revolt against the Church of Rome, but multitudes were lending a friendly ear to the Reformed doctrines, and a few were in secret rejoicing in having heartily embraced them To such Calvin united himself whilst at Orleans, and after his removal to Bourges he became a teacher, both in private conference with inquirers and by discourses in more public assemblies. "Before a year had elapsed," says he, speaking of his conversion,—"all who were desirous of a purer doctrine were in the habit of coming to me, though a novice and a tyro, for the purpose of learning."[2] And Beza tells us that he not only fortified the few believers who were in the town, but preached often in some of the neighbouring mansions and hamlets, whereby he wonderfully advanced the kingdom of God in many families, among which he specifies that of the lord of Ligniéres, who with his lady heard with approval the new doctrines.[3] In engaging in such efforts, Calvin appears to have yielded to a constraining sense of duty rather than to have followed the bias of his own inclinations. "By nature," says he, "somewhat clownish (*subrusticus*), I always preferred the shade and ease, and would have sought some hiding-place ; but this was not permitted, for all my retreats became like public schools."[4] Nor did he infuse any of the enthusiasm which usually marks the young reformer into his addresses. "He taught the truth," says Beza, "not with affected eloquence, but with such depth of knowledge and so much solid gravity of style, that there was not a man who could hear him without being ravished with admiration."[5]

His residence at Bourges was cut short by the sudden death of his father, which occasioned his return to his native place. Immediately after his father's decease, he seems to have paid a hasty visit to Paris, and then to have returned to Noyon, where he resided for a couple of years or so. At the close of this period he appears to have returned to Paris, where he apparently resided from 1529 to 1532, as letters written by him are dated from Paris in these years. While there he lodged with a tradesman, Etienne de la Forge, who early fell a victim to his zeal for the Reformation, and "whose memory," Calvin says, "should be blessed among believers as a holy martyr for Christ."[6] In his house the friends of evangelical truth were wont to meet, and Calvin not only associated with them, but frequently preached in their assemblies. To the great joy of all such, he at length entirely relinquished his legal pursuits and devoted himself afresh to theology, —giving himself up wholly to the work, preaching with great energy, and using all the means in his power to win converts to the truth, as well as to confirm those by whom it had been already embraced. By this time the Reformation had attracted so many adherents in France, that the upholders of the established system became infuriated, and attempted to stay its further progress by the most cruel persecutions. It was whilst these were raging that Calvin issued his first publication, an edition of Seneca's tract *De Clementia*, with an elaborate commentary. This book he published at his own cost, and dedicated to Claude Hangest, abbot of St Eloi, a member of the De Montmor family, with whom Calvin had been brought up. The commentary, which is written in that pure and terse Latinity which characterizes all Calvin's works composed in the language of ancient Rome, displays extensive acquaintance with ancient literature, though the author has fallen into the extraordinary mistake of running the two Senecas, father and son, into one, and making the philosopher die 115 years old. It has been suggested that Calvin published this work with a view to influence the king to put a stop to the persecution of the Protestants, but there is nothing in the treatise itself or in the commentary to favour this opinion.

This work was published in April 1532, and seems to have brought Calvin more of honour than of profit. It appears, indeed, that he had some difficulty in paying the cost of its publication; and it is probable that it was partly in order to meet this that he sold at this time the slender patrimony which his father had left him. He at this time also relinquished the ecclesiastical preferments which he had hitherto continued to hold, an act which, though demanded by the change that had taken place in his religious views, was entirely voluntary on his part, and, when viewed in connection with his then straitened circumstances, must be put to the credit of his integrity and disinterestedness. He was now in his twenty-fourth year, and was already recognized as at the head of the Reformation movement in France. An occasion soon occurred which brought him into open collision with the dominant party. Nicholas Cop, the newly-elected regent of the Sorbonne, had to deliver an oration according to custom in the Church of the Maturins, on the feast of All Saints. Being intimate with Calvin, he pronounced an oration which the latter had prepared for him, "of a totally different sort," says Beza, "from what was customary."[7] It was, in fact, a defence of the Reformed opinions, especially of the doctrine of justification by faith alone. This was more than the Sorbonnists could bear, and Cop, being summoned to appear before the parliament, found it necessary to make his escape from Paris to Basel. An attempt was at the same time made to seize Calvin, but being forewarned of the design by his friends, he also made his escape. His lodgings, however, were searched, and his books and papers seized, to the imminent peril of some of his friends, whose letters were found in his repositories. He himself retired first to the castle of Lord de Hazeville near Mantes, and after that to Saintonge, where he was the guest of Louis du Tillet, a canon of Angoulême, and where at the request of his host he prepared some short discourses, which were circulated in the surrounding parishes, and read in public to the people. He subsequently removed to Nerac, the residence of the queen of Navarre, the only sister of Francis I., who then favoured the Reformers, and through whose intercession the storm that had broken out against them was for the time abated. Here he became acquainted with the venerable Jacques Lefevre d' Estaples, a scholar and man of science, whom the queen had rescued from the fury of the Sorbonnists, and engaged as tutor to her children. By him Calvin was warmly received, and his future eminence as a reformer of the church predicted.

It has been asserted that it was whilst resident at Saintonge that Calvin prepared the first sketch of his *Institutio Christianæ Religionis*; but this has not been proved. His residence in that retirement continued only

for a very few months; for, in 1534, we find him first at Noyon, his native place, and soon after again in Paris. Here he was compelled to remain concealed, in consequence of the measures which the enemies of the Reformation were still pursuing against its adherents. At the risk of his life, however, he came forth to meet one whom he was afterwards to encounter under very different circumstances, the Spanish physician, Servede or Servetus, who was even then engaged in propagating his heretical notions concerning the Trinity. Servetus having expressed a desire to have a conference with Calvin, it was arranged that they should meet and discuss their conflicting opinions; but though Calvin waited for him long at the time and place appointed, Servetus failed to make his appearance, "being," says Beza, "unable to endure the sight of Calvin," but more probably deterred by the danger to which both were exposed from the hostility of the ruling powers. Calvin's design in acceding to this colloquy seems to have been a kindly one towards Servetus. "Not without danger to my life," he himself says, "I offered to deliver him from his errors."[1] Nor was Servetus the only errorist whom Calvin endeavoured at this time to confute. The Anabaptists of Germany had spread into France, and were disseminating many wild and fanatical opinions among those who had seceded from the Church of Rome. Among other notions which they had imbibed, was that of a sleep of the soul after death. To Calvin this notion appeared so pernicious, that he composed and published a treatise in refutation of it, under the title of *Psychopannychia.* In this work he chiefly dwells upon the evidence from Scripture in favour of the belief that the soul retains its intelligent consciousness after its separation from the body,—passing by questions of philosophical speculation, as tending on such a subject only to minister to an idle curiosity.

The *Psychopannychia* was published in 1534 at Orleans, whither Calvin had been constrained, in consequence of the violence of the persecution at Paris, to retreat. On his way thither he stopped for some time at Poitiers. Here many gathered round him desirous of instruction from him; and in a grotto near the town he celebrated for the first time the communion in the Evangelical Church of France, using a piece of the rock as a table. From this time forward his influence became supreme, and all who had imbibed or become tinged with the Reformed doctrines in France turned to him for counsel and instruction, attracted not only by his power as a teacher, but still more, perhaps, because they saw in him so full a development of the Christian life according to the evangelical model. M. Renan, no prejudiced judge, pronounces him "the most Christian man of his time," and attributes to this his success as a reformer. Certain it is that already he had drawn upon him the notice of those who were seeking to extinguish in blood the light which had been kindled, and which he was so prompt to hold up to view; so that he was obliged to seek safety in flight. In company with his friend Louis du Tillet, whom he had again gone to Angoulême to visit, he set out for Basel. On their way they were robbed by one of their servants, who so entirely stripped them of their property, that it was only by borrowing ten crowns from their other servant that they were enabled to get to Strasburg, and thence to Basel. Here Calvin was welcomed by the band of scholars and theologians who had conspired to make that city the Athens of Switzerland, and especially by the learned Simon Grynæus, and by Wolfgang Capito, the leader of the Reformation at Basel. Under the auspices and guidance of the latter, Calvin applied himself to the study of Hebrew.

Francis I., desirous to continue the persecution of the Protestants, but anxious at the same time not to break with the Protestant princes of Germany, resorted to the unworthy expedient of instructing his ambassador to assure the latter that it was only against the Anabaptists, and other parties who called in question all civil magistracy, that his severities were exercised. Calvin, indignant at the calumny which was thus cast upon the Reformed party in France, hastily prepared for the press his *Institutes of the Christian Religion*, which he published as a confession of the Reformed faith, and dedicated to the king. This work Calvin says he wrote in Latin that it might find access to the learned in all lands.[2] Soon after it appeared he set about translating it into French, as he himself attests in a letter dated October 1536. This sets at rest a question, at one time much agitated, whether the book appeared first in French or in Latin. The earliest French edition known is that of 1540, and this was after the work had been much enlarged, and several Latin editions had appeared. In its first form the work consisted of only six chapters, and was intended merely as a brief manual of Christian doctrine. It appeared anonymously, the author having, as he himself says, nothing in view beyond furnishing a statement of the faith of the persecuted Protestants, whom he saw cruelly cut to pieces by impious and perfidious court parasites.[3] In this work, though produced when the author was only twenty-five years of age, we find a complete outline of that theological system which has since borne his name. In none of the later editions, nor in any of his later works, do we find reason to believe that he ever changed his views on any essential point from what they were at the period of its first publication. Such an instance of maturity of mind and of opinion at so early an age, would be remarkable under any circumstances; but in Calvin's case it is rendered peculiarly so, by the shortness of the time which had elapsed since he gave himself to theological studies. It may be doubted also if the history of literature presents us with another instance of a book written at so early an age, which has exercised such a prodigious influence upon the opinions and practices both of contemporaries and of posterity.

After a short visit to the court of the duchess of Ferrara, which at that time afforded an asylum to several learned and pious fugitives from persecution, Calvin returned to France to arrange his affairs before finally taking farewell of his native country. His intention was to settle at Basel, and to devote himself to study. But being unable, in consequence of the disturbed state of the country, to reach Basel by the ordinary route, he had to take the route through Geneva. Whilst in this city his further progress was arrested, and his resolution to pursue the quiet path of studious research was dispelled, by what he calls the "formidable obtestation" of Farel.[4] After many struggles and no small suffering, this energetic spirit had succeeded in planting the evangelical standard at Geneva; and anxious to secure the aid of such a man as Calvin, he entreated him on his arrival to relinquish his design of going farther, and to devote himself to the work in that city. Calvin at first declined, alleging as an excuse his need of securing more time for personal improvement, which could not be obtained were he engaged in ministerial work. To the ardent Farel this seemed a mere pretext for indolence. "I tell you," he continued, "in answer to this pretence of your studies, in the name of Almighty God, that if you will not devote yourself with us to this work of the Lord, the Lord will curse you as one seeking not Christ so much as himself." Startled by this denunciation, and feeling as if God had laid his hand on him to detain him, Calvin consented to remain at Geneva, where

[2] This edition forms a small 8vo of 514 pages, and 6 pages of index. It appeared at Basel from the press of Thomas Platter and Balthasar Lasius in March 1536.

[3] *Præf. ad Psalmos.*

[4] *Ibid.*

he was immediately appointed teacher of theology. He was also elected preacher by the magistrates with the consent of the people, but this office he would not accept until it had been repeatedly pressed upon him. His services seem to have been rendered for some time gratuitously, for in February 1537, there is an entry in the city registers to the effect that six crowns had been voted to him, "since he has as yet hardly received anything."

Calvin was in his twenty-eighth year when he was thus constrained to settle at Geneva; and in this city the rest of his life, with the exception of a brief interval, was spent. The post to which he was thus called was not an easy one. Though the people of Geneva had cast off the yoke of Rome, they were still "but very imperfectly enlightened in divine knowledge; they had as yet hardly emerged from the filth of the papacy."[1] This laid them open to the incursions of those fanatical teachers, whom the excitement attendant upon the Reformation had called forth, and who hung mischievously upon the rear of the reforming body. To obviate the evils thence resulting, Calvin, in union with Farel, drew up a condensed statement of Christian doctrine consisting of twenty-one articles. This the citizens were summoned, in parties of ten each, to profess and swear to as the confession of their faith—a process which, though not in accordance with modern notions of the best way of establishing men in the faith, was gone through, Calvin tells us, "with much satisfaction." As the people took this oath in the capacity of *citizens*, we may see here the basis laid for that theocratic system which subsequently became peculiarly characteristic of the Genevan polity. Deeply convinced of the importance of education for the young, Calvin and his coadjutors were solicitous to establish schools throughout the canton, and to enforce on parents the sending of their children to them; and as he had no faith in education apart from religious training, he drew up an elementary catechism of Christian doctrine which the children had to learn whilst they were receiving secular instruction. Of the troubles which arose from fanatical teachers, the chief proceeded from the efforts of the Anabaptists; but these Calvin and his colleagues so effectually silenced by means of a public disputation held on the 18th of March 1537, that they never afterwards appeared at Geneva. In the course of this year also, the peace of Calvin and his friends was much disturbed, and their work interrupted, by a turbulent and unprincipled preacher named Peter Caroli, who, after many changes of religious profession (with none of which, however, had he associated anything of true religion, or even much of ordinary morality), had assumed the character of a stickler for orthodoxy. In this character he accused the Geneva divines of Sabellianism and Arianism, because they would not enforce the Athanasian creed, and had not used the words "Trinity" and "Person" in the confession they had drawn up. In a synod held at Bern the matter was fully discussed, when a verdict was given in favour of the Geneva divines, and Caroli deposed from his office and banished. Thus ended an affair which seems to have occasioned Calvin much more uneasiness than the character of his assailant, and the manifest falsehood of the charge brought against him, would seem to justify. Two brief tracts, intended to expose the evils and warn against the seductions of Popery, one entitled *De Fugienda Idolatria*, the other *De Papisticis Sacerdotiis*, must be added to the labours of Calvin this year.

Hardly was the affair of Caroli settled, when new and severer trials came upon the Genevan Reformers. The severe simplicity of the ritual which Farel had introduced, and to which Calvin had conformed; the strictness with which the ministers sought to enforce not only the laws of morality, but certain sumptuary regulations respecting the dress and mode of living of the citizens; and their determination in spiritual matters not to submit to the least dictation from the civil power, led to such violent dissensions that Calvin and his colleagues refused to administer the sacrament to the people. For this they were banished from the city. They went first to Bern, and soon after to Zurich, where a synod of the Swiss pastors had been convened. Before this assembly they pleaded their cause, and stated what were the points on which they were prepared to insist as needful for the proper discipline of the church. They declared that they would yield in the matter of ceremonies so far as to employ unleavened bread in the eucharist, to use fonts in baptism, and to allow festival days, provided the people might pursue their ordinary avocations after public service. These Calvin regarded as matters of indifference, provided the magistrates did not make them of importance, by seeking to enforce them; and he was the more willing to concede them, because he hoped thereby to meet the wishes of the Bernese brethren, whose ritual was less simple than that established by Farel at Geneva. But he and his colleagues insisted, on the other hand, that for the proper maintenance of discipline, there should be a division of parishes—that excommunications should be permitted, and should be under the power of elders chosen by the council, in conjunction with the clergy—that order should be observed in the admission of preachers—and that only the clergy should officiate in ordination by the laying on of hands. It was proposed also, as conducive to the welfare of the church, that the sacrament of the Lord's Supper should be administered more frequently, at least once every month, and that congregational singing of psalms should be practised in the churches. On these terms the synod interceded with the Genevese to restore their pastors; but through the opposition of the Bernese this was frustrated, and a second edict of banishment was the only response.

Calvin and Farel betook themselves, under these circumstances, to Basel, where they soon after separated, Farel to go to Neufchatel, and Calvin to Strasburg. At the latter place Calvin resided till the autumn of 1541, occupying himself partly in literary exertions, partly as a preacher in the French church, and partly as a lecturer on theology. In 1539 he attended the convention at Frankfort as the companion of Bucer, and in the following year he appeared at that at Hagenau and Worms, as the delegate from the city of Strasburg. He was present also at the diet at Ratisbon, where he became personally acquainted with Melanchthon, and formed with him a friendship which lasted through life. It is to this period of his life that we owe the completed form of his *Institutio*, his Commentary on the Epistle to the Romans, and his Tract on the Lord's Supper. Notwithstanding his manifold engagements, he found time to attend to the tenderer affections; for it was during his residence at Strasburg that he married Idelette de Bures or van Buren, the widow of a person named Störder, whom he had converted from Anabaptism. In her Calvin found, to use his own words, "the excellent companion of his life," a "precious help" to him amid his manifold labours and frequent infirmities. She died, in 1549, to the great grief of her husband, who never ceased to mourn her loss.

During his absence, disorder and irreligion had prevailed in Geneva. An attempt was made by Sadolet, bishop of Carpentras, to take advantage of this so as to restore the papal supremacy in that district; but this design Calvin, watchful over the interests of his ungrateful flock, though exiled from them, completely frustrated by writing such a reply to the letter which the bishop had addressed to the

[1] Beza, *Vit. Calv. an.* 1536.

Genevese, as constrained him to desist from all further efforts. He seems also to have kept up his connection with Geneva by addressing letters of counsel and comfort to the faithful there who continued to regard him with affection. It was whilst he was still at Strasburg that there appeared at Geneva a translation of the Bible into French, bearing Calvin's name, but in reality only revised and corrected by him from the version of Olivetan. Meanwhile the way had been opened for his return to the post whence he had been driven in that city. In the summer of 1541, the decree of his banishment was revoked, and in the following September he yielded to the earnest entreaties of his now penitent flock, and returned to Geneva, where he was received with the utmost enthusiasm. He entered upon his work with a firm determination to carry out those reforms which he had originally purposed, and to set up in all its integrity that form of church policy which he had carefully matured during his residence at Strasburg. He now became the sole directive spirit in the church at Geneva. Farel was retained by the Neufchatelois, and Viret, soon after Calvin's return, removed to Lausanne. His duties were thus rendered exceedingly onerous, and his labour became excessive. Besides preaching every day in each alternate week, he taught theology three days in the week, attended weekly meetings of his consistory, read the Scriptures once a week in the congregation, carried on an extensive correspondence on a multiplicity of subjects, prepared commentaries on the books of Scripture, and was engaged repeatedly in controversy with the opponents of his opinions. "I have not time," he writes to a friend, "to look out of my house at the blessed sun, and if things continue thus, I shall forget what sort of appearance it has. When I have settled my usual business, I have so many letters to write, so many questions to answer, that many a night is spent without any offering of sleep being brought to nature." We cannot in this sketch follow him through all the details of his brief but busy life after he returned to Geneva; we can only afford to notice slightly the leading events.

Of the controversies in which Calvin embarked, one of the most important was that in which he defended his doctrine concerning predestination and election. His first antagonist on this head was Pighius, a Romanist, who, resuming the controversy between Erasmus and Luther on the freedom of the will, violently attacked Calvin for the views he had expressed on that subject. Calvin replied to him in a work published in 1543, in which he defends his own opinions at length, as well by general reasonings as by an appeal to both Scripture and the Fathers, especially Augustine. So potent were his reasonings in the esteem of his opponent, that the latter, though owing nothing to the gentleness or courtesy of Calvin, was led to embrace his views. A still more vexatious and protracted controversy on the same subject arose in 1551, in which Calvin was called to defend his views against Bolsec, originally a Carmelite friar, but who having renounced Romanism had fled from France and come to Geneva, where he appeared as a physician. In becoming a physician, however, he had not relinquished theological studies, and being a zealous opponent of predestinarian views, he was tempted on one occasion, after a sermon on the subject by Calvin to attack him in the public assembly. Calvin replied with equal vehemence; and an officer of police, scandalized that such a scene should occur in church, took Bolsec into custody. The pastors resolved to have a conference with him before the council; and for two days the discussion was conducted by him and Calvin with much ability on both sides. The council were at a loss what course to take; not that they doubted which of the disputants was right, for they all held by the views of Calvin, but they were unable to determine to what extent and in which way Bolsec should be punished for his heresy. The question was submitted to the Swiss churches, but they also were divided in their judgment, some counselling severity, others gentle measures. The result was that Bolsec was banished from Geneva. The enemies of Calvin insinuated that he counselled the infliction of a heavier penalty; but this he himself in a letter to Bullinger indignantly denies. In this controversy ultimately several others, including Castellio, Fabri, and even Bullinger and Melanchthon took part against Calvin, and only Beza appeared as a zealous coadjutor. But the most memorable of all the controversies in which Calvin was engaged, was that into which he was brought in 1553 with his old antagonist Servetus. After many wanderings, and after having been condemned to death for heresy at Vienne, from which he was fortunate enough to make his escape, Servetus arrived in July 1553 at Geneva. He appears to have remained in quiet here for some time, and was about to leave for Zurich when, at the instigation of Calvin, he was arrested and conveyed to prison on the charge of blasphemy. This charge was founded on certain statements in a book published by him in 1553, entitled *Christianismi Restitutio*, in which he animadverted in terms needlessly offensive on the Catholic doctrine of the Trinity, and advanced sentiments strongly savouring of Pantheism.[1] At the trial which followed Calvin appeared as his accuser, and the conflict was conducted between the two with much ability on both sides, and at the same time with no small keenness and bitterness. After a protracted trial, the accused was condemned to be burnt to death, and was accordingly burned at Champel near Geneva, on the 27th of October 1553. Farel attended him in his last hours, and accompanied him to the place of execution. He had an interview also with Calvin on the morning of the fatal day, when he asked his forgiveness, but refused to retract any of his expressions. Calvin has been much censured, not to say vituperated, for his share in this unhappy transaction. In order to aggravate the charge against him it has been alleged that it was by his invitation that Servetus came to Geneva, that it was by his urgency that the magistrates, over whom his influence was unbounded, condemned Servetus to death, and that it was to gratify a personal pique and through hatred of Servetus that he thus cruelly and relentlessly pursued him. Of these allegations not one can be proved, and some are undoubtedly false. It is not true that Calvin induced Servetus to come to Geneva; on the contrary, when Servetus intimated a wish to visit that city if it pleased Calvin that he should do so, Calvin intimated very plainly that it did not please him, and refused to pledge himself for his safety should he come, as he was resolved, should he come, to prosecute him to the death.[2] That Calvin influenced the magistrates to condemn Servetus is true only in the same sense in which any public prosecutor who pleads before the judge for the condemnation of one against whom he brings a criminal charge, may be said to influence the judge to condemn him. As for the assertion that Calvin's influence with the magistrates was unbounded, this falls to the ground before the fact that at this time he was in a state of antagonism with the dominant party.[3] That Calvin hated the doctrines which he found in Servetus's book there can be no doubt, and that he thought the author of such views as were there advanced

[1] A digest of Servetus's views is given by Dorner, *Entwickelungsgeschichte der Lehre von d. Person Christi*, ii. pp. 649–656, Eng. trans. div. ii., vol. ii. pp. 161–168.

[2] Si mihi placeat huc se venturum recipit. Sed nolo fidem meam interponere. Nam si modo valeat mea autoritas vivum exire nunquam patiar.—Calvin to Farel, 12th Feb. 1546.

[3] See art. "Servet" by Trechsel in Herzog's *Real-Encyclopädie*, v. xiv. p. 297.

deserving of death, if he refused when reasoned with to recant, is unhappily true; but that he was actuated by personal spite and animosity against Servetus himself there is no evidence; on the contrary we have his own express declaration that, after Servetus was convicted, he used no urgency that he should be put to death, and at their last interview he told Servetus that he never had avenged private injuries, and assured him that if he would repent it would not be his fault if all the pious did not give him their hands.[1] There is the fact also that Calvin used his endeavour to have the sentence which had been pronounced against Servetus mitigated, death by burning being regarded by him as an "atrocity," for which he sought to substitute death by the sword.[2] All that can be justly charged against Calvin in this matter is that he took the initiative in bringing on the trial of Servetus, that as his accuser he prosecuted the suit against him with undue severity, and that he approved the sentence which condemned Servetus to death. When, however, it is remembered that the unanimous decision of the Swiss churches and of the Swiss state Governments was that Servetus deserved to die; that the general voice of Christendom was in favour of this; that even such a man as Melanchthon affirmed the justice of the sentence;[3] that an eminent English divine of the next age should declare the process against him "just and honourable,"[4] and that only a few voices here and there were at the time raised against it, candid and impartial men will be ready to accept the judgment of Coleridge, that the death of Servetus was not "Calvin's guilt especially, but the common opprobrium of all European Christendom."[5]

The heresy of Servetus was not extirpated by his death, but none of his followers were visited with severer penalties than that of banishment from Geneva. The trials of several of these, with the conferences and controversies connected with them, occupied much of Calvin's time for several years. He was also involved in a protracted and somewhat vexing dispute with the Lutherans respecting the Lord's Supper, which ended in the separation of the evangelical party into the two great sections of Lutherans and Reformed,—the former of whom hold that in the eucharist the body and blood of Christ are objectively and consubstantially present, and so are actually partaken of by the communicants, whilst the latter maintain that there is only a virtual presence of the body and blood of Christ, and consequently only a spiritual participation thereof through faith. In connection with these controversies on points of faith, Calvin was for many years greatly disquieted, and sometimes even endangered, by the opposition offered by the libertine party in Geneva to the ecclesiastical discipline which he had established there. His system of church polity was essentially theocratic; it assumed that every member of the state was also under the discipline of the church; and he asserted that the right of exercising this discipline was vested exclusively in the consistory or body of preachers and elders. His attempts to carry out these views brought him into collision both with the authorities and with the populace,—the latter being enraged at the restraints imposed upon the disorderly by the exercise of church discipline, and the former being inclined to retain in their own hands a portion of that power in things spiritual which Calvin was bent on placing exclusively in the hands of the church rulers. His dauntless courage, his perseverance, and his earnestness at length prevailed, and he had the satisfaction, before he died, of seeing his favourite system of church polity firmly established, not only at Geneva, but in other parts of Switzerland, and of knowing that it had been adopted substantially by the Reformers in France and Scotland. Nor was it only in religious matters that Calvin busied himself; nothing was indifferent to him that concerned the welfare and good order of the state or the advantage of its citizens. His work, as has been justly said, "embraced everything;" he was consulted on every affair, great and small, that came before the council,—on questions of law, police, economy, trade, and manufactures, no less than on questions of doctrine and church polity. To him Geneva owed her trade in cloths and velvets, from which so much wealth accrued to her citizens; sanitary regulations were introduced by him which made Geneva the admiration of all visitors; and in him she reverences the founder of her college, which still flourishes, and from which so many learned men have gone forth.

Amidst these multitudinous cares and occupations, Calvin found time to commit to writing a number of works besides those provoked by the various controversies in which he was engaged. The most numerous of these were of an exegetical character. Including discourses taken down from his lips by faithful auditors, we have from him expository comments or homilies on nearly all the books of Scripture, written partly in Latin and partly in French. In the estimation of many, these constitute the most valuable of his works. His candour and sincerity as an inquirer into the meaning of Scripture—his judiciousness, penetration, and tact in eliciting his author's meaning—his precision, condensation, and concinnity as an expositor—the accuracy of his learning, the closeness of his reasoning, and the elegance of his style, all conspire to confer a high value on his exegetical works, and to make them at once rich sources of biblical knowledge and admirable models of biblical exposition.

But it is chiefly as a theologian and the head of a theological school that Calvin is now known. This renders it fitting that some account should be here given of his theological system. This is developed in his *Institutio*, which, though produced originally at an early period of his life, was so frequently and carefully revised by him, that in the form in which it has come down to us it presents his most matured views and thoughts. In some of his tracts and polemical writings certain of his doctrines are more fully expounded, illustrated, and defended; but nowhere has he advocated any tenet which is not in substance to be found in the *Institutio*.

Much of Calvin's theology is common to him with all evangelical divines, and in the parts which are more peculiar to him and his school he follows closely in the steps of Augustine. The following may be regarded as his characteristic tenets, though all are not peculiar to him.

Man as a sinner is guilty and corrupt. The first man was made in the image and likeness of God, which not only implies man's superiority to all other creatures, but indicates his original purity, integrity, and sanctity. From this state Adam fell, and in his fall involved the whole human race descended from him. Hence depravity and corruption, diffused through all parts of the soul, attach to all men, and this first makes them obnoxious to the anger of God, and then comes forth in works which the Scripture calls works of the flesh (Gal. v. 19). Thus all are held vitiated and perverted in all parts of their nature, and on account of such corruption deservedly condemned before God, by whom nothing is accepted save righteousness, innocence, and purity. Nor is that a being bound for another's offence; for when it is

[3] Tuo judicio prorsus assentior. Affirmo etiam vestros magistratus juste fecisse quod hominem blasphemum, re ordine judicata, interfecerunt.—Melanchthon to Calvin, 14th Oct. 1554.
[4] Field *On the Church*, bk. iii. c. 27, vol. i. p. 288, ed. Camb. 1847.
[5] *Notes on English Divines*, vol. i. p. 49. See also *Table Talk*, vol. ii. p. 252, ed. 1835

said that we through Adam's sin have become obnoxious to the divine judgment, it is not to be taken as if we, being ourselves innocent and blameless, bear the fault of his offence, but that, we having been brought under a curse through his transgression, he is said to have bound us. From him, however, not only has punishment overtaken us, but a pestilence instilled from him resides in us, to which punishment is justly due. Thus even infants, whilst they bring their own condemnation with them from their mother's womb, are bound not by another's but by their own fault. For though they have not yet brought forth the fruits of their iniquity, they have the seed shut up in them; nay, their whole nature is a sort of seed of sin, therefore it cannot but be hateful and abominable to God (*Instit.* bk. ii. ch. i. sect. 8).

To redeem man from this state of guilt, and to recover him from corruption, the Son of God became incarnate, assuming man's nature into union with His own, so that in Him were two natures in one person. Thus incarnate He took on Him the offices of Prophet, Priest, and King, and by His humiliation, obedience, and suffering unto death, followed by His resurrection and ascension to heaven, He has perfected His work and fulfilled all that was required in a Redeemer of men, so that it is truly affirmed that He has merited for man the grace of salvation (bk. ii. ch. 13–17). But until a man is in some way really united to Christ so as to partake of Him, the benefits of Christ's work cannot be attained by him. Now it is by the secret and special operation of the Holy Spirit that men are united to Christ and made members of His body. Through faith, which is a firm and certain cognition of the divine benevolence towards us founded on the truth of the gracious promise in Christ, men are by the operation of the Spirit united to Christ and are made partakers of His death and resurrection, so that the old man is crucified with Him and they are raised to a new life, a life of righteousness and holiness. Thus joined to Christ the believer has life in Him and knows that he is saved, having the witness of the Spirit that he is a child of God, and having the promises, the certitude of which the Spirit had before impressed on the mind, sealed by the same Spirit on the heart (bk. iii. ch. 33–36). From faith proceeds repentance, which is the turning of our life to God, proceeding from a sincere and earnest fear of God, and consisting in the mortification of the flesh and the old man within us and a vivification of the Spirit. Through faith also the believer receives justification, his sins are forgiven, he is accepted of God, and is held by Him as righteous, the righteousness of Christ being imputed to him, and faith being the instrument by which the man lays hold on Christ, so that with His righteousness the man appears in God's sight as righteous. This imputed righteousness, however, is not disjoined from real personal righteousness, for regeneration and sanctification come to the believer from Christ no less than justification; the two blessings are not to be confounded, but neither are they to be disjoined. The assurance which the believer has of salvation he receives from the operation and witness of the Holy Spirit; but this again rests on the divine choice of the man to salvation; and this falls back on God's eternal sovereign purpose, whereby He has predestinated some to eternal life while the rest of mankind are predestinated to condemnation and eternal death. Those whom God has chosen to life He effectually calls to salvation, and they are kept by Him in progressive faith and holiness unto the end (bk. iii. *passim*). The external means or aids by which God unites men into the fellowship of Christ, and sustains and advances those who believe, are the church and its ordinances, especially the sacraments. The church universal is the multitude gathered from diverse nations, which though divided by distance of time and place, agree in one common faith, and it is bound by the tie of the same religion; and wherever the word of God is sincerely preached, and the sacraments are duly administered, according to Christ's institute, there beyond doubt is a church of the living God (bk. iv. ch. 1, sect. 7–11). The permanent officers in the church are pastors and teachers, to the former of whom it belongs to preside over the discipline of the church, to administer the sacraments, and to admonish and exhort the members; while the latter occupy themselves with the exposition of Scripture, so that pure and wholesome doctrine may be retained. With them are to be joined for the government of the church certain pious, grave, and holy men as a senate in each church; and to others, as deacons, is to be entrusted the care of the poor. The election of the officers in a church is to be with the people, and those duly chosen and called are to be ordained by the laying on of the hands of the pastors (ch. 3, sect. 4–16). The sacraments are two—Baptism and the Lord's Supper. Baptism is the sign of initiation whereby men are admitted into the society of the church and, being grafted into Christ, are reckoned among the sons of God; it serves both for the confirmation of faith and as a confession before men. The Lord's Supper is a spiritual feast where Christ attests that He is the life-giving bread, by which our souls are fed unto true and blessed immortality. That sacred communication of His flesh and blood whereby Christ transfuses into us His life, even as if it penetrated into our bones and marrow, He in the Supper attests and seals; and that not by a vain or empty sign set before us, but there He puts forth the efficacy of His Spirit whereby He fulfils what He promises. In the mystery of the Supper Christ is truly exhibited to us by the symbols of bread and wine; and so his body and blood, in which He fulfilled all obedience for the obtaining of righteousness for us, are presented. There is no such presence of Christ in the Supper as that He is affixed to the bread or included in it or in any way circumscribed; but whatever can express the true and substantial communication of the body and blood of the Lord, which is exhibited to believers under the said symbols of the Supper, is to be received, and that not as perceived by the imagination only or mental intelligence, but as enjoyed for the aliment of the eternal life (bk. iv. ch. 15, 17).

The incessant and exhausting labours to which Calvin gave himself, could not but tell on the strongest constitution: how much more on one so fragile as his! Amid many sufferings, however, and frequent attacks of sickness, he manfully pursued his course for twenty-eight years; nor was it till his frail body, torn by many and painful diseases—fever, asthma, stone, and gout, the fruits for the most part of his sedentary habits and unpausing activity—had, as it were, fallen to pieces around him, that his indomitable spirit relinquished the conflict. In the early part of the year 1564 his sufferings became so severe that it was manifest his earthly career was rapidly drawing to a close. On the 6th of February of that year he preached his last sermon, having with great difficulty found breath enough to carry him through it. He was several times after this carried to church, but never again was able to take any part in the service. With a noble disinterestedness he refused to receive his stipend, now that he was no longer able to discharge the duties of his office. In the midst of his sufferings, however, his zeal and energy kept him in continual occupation; when expostulated with for such unseasonable toil, he replied, "Would you that the Lord should find me idle when He comes?" After he had retired from public labours he lingered for some months, enduring the severest agony without a murmur, and cheerfully attending to all the duties of a private kind which his

iseases left him strength to discharge. A deep impression ɔems to have been made on all who visited him on his eathbed; they saw in him the noble spectacle of a great pirit that had done its life-work, calmly and trustfully assing through the gate of suffering into the long-desired nd firmly-expected repose of heaven. He quietly expired ı the arms of his faithful friend Beza, on the evening of he 27th of May, in the fifty-fifth year of his age.

Calvin was of middle stature; his complexion was omewhat pallid and dark; his eyes, to the latest clear and ıstrous, bespoke the acumen of his genius. He was sparing ı his food and simple in his dress; he took but little sleep, nd was capable of extraordinary efforts of intellectual toil. Iis memory was prodigious, but he used it only as the ervant of his higher faculties. As a reasoner he has seldom ɔeen equalled, and the soundness and penetration of his udgment were such as to give to his conclusions in practical ɥuestions almost the appearance of predictions, and inspire n all his friends the utmost confidence in the wisdom of iis counsels. As a theologian he stands on an eminence vhich only Augustine has surpassed; whilst in his skill as ın expositor of Scripture, and his terse and elegant style, ıe possessed advantages to which Augustine was a stranger. Iis private character was in harmony with his public eputation and position. If somewhat severe and irritable, ıe was at the same time scrupulously just, truthful, and ıteadfast; he never deserted a friend or took an unfair ıdvantage of an antagonist; and on befitting occasions he could be cheerful and even facetious among his intimates. "I have been a witness of him for sixteen years," says Beza, "and I think I am fully entitled to say that in this man there was exhibited to all an example of the life and death of the Christian, such as it will not be easy to depreciate, such as it will be difficult to emulate."[1] (W. L. A.)

CALVISIUS, Sethus (1556–1617), a German astronomer and chronologer, was born at Groschleben, in Thuringia, in 1556. He studied at Helmstädt, where he made great progress in classical literature, as well as in the sciences in which he afterwards became so distinguished. He was offered a professorship of mathematics at Frankfort, and afterwards one at Wittenberg, both of which he declined. He agreed, however, to conduct the school of music, established at Pforte,—an office which he afterwards exchanged for a similar situation at Leipsic. At Frankfort he published, in 1585, his *Opus Chronologicum*, a work compiled on astronomical principles. He likewise organized a system of chronology, embodying the history of the world, upon an ingenious and original plan, highly commended by Casaubon and Scaliger. This work, which was strongly condemned in the *Index Expurgatorius*, has been frequently reprinted. In 1612 Calvisius published his *Elenchus Calendarii Gregoriani, et duplex Calendarii melioris forma*, in which he attempts to prove the inadequacy of the Gregorian calendar, and proposes to introduce a new system based upon astronomical principles. The only proof now extant of his musical knowledge is his treatise entitled *Melodiæ condendæ ratio*. He died at Leipsic in 1617.

[1] *Vit. Calv. sub fin.* This is the principal source for the facts of Calvin's life. Beza's narrative has been expanded and illustrated from other sources by Dr Henry in his *Leben Calvins*, of which an English translation has appeared in 2 vols. 8vo, by the Rev. H. Stebbing. Audin has written a life of Calvin in French, full of misrepresentations and blunders. A highly respectable work has appeared on the same subject from the pen of M. Dyer, in 1 vol. 8vo. M. Bungener has also recently sent forth a *Life of Calvin*, which has been translated into English, Edin., 1863. Of Calvin's works, two editions appeared at Geneva, one in 12 vols. fol. in 1578, the other in 7 vols. fol. in 1617. An edition, hitherto reputed the best, was published at Amsterdam in 9 vols. fol. in 1671. A new edition in 4to is at present in course of publication, carefully edited by G. Baum, E. Cunitz, and E. Reuss, at Brunswick. An English translation has been issued at Edinburgh in 53 vols. 8vo.

CALYDON (Καλυδών), an ancient town of Ætolia, 7½ miles from the sea, on the River Evenus. It was said to have been founded by Calydon, son of Ætolus; to have been the scene of the hunting, by Meleager and other heroes, of the famous Calydonian boar, sent by Artemis to lay waste the fields; and to have taken part in the Trojan war. In historical times, it is first mentioned (391 B.C.) as in the possession of the Achæans, who retained it for twenty years, by the assistance of the Lacedæmonian king Agesilaus, notwithstanding the attacks of the Acarnanians. After the battle of Leuctra (371 B.C.) it was restored by Epaminondas to the Ætolians. In the time of Pompey it was a town of importance; but Augustus removed its inhabitants to Nicopolis, which he founded to commemorate his victory at Actium (31 B.C.)

CALYPSO, in Grecian mythology, was a daughter of Oceanus and Tethys, or of Nereus, or of Atlas, and reigned in the mythical island of Ogygia. When Ulysses was shipwrecked on her shores, Calypso entertained the hero with great hospitality; and by the united influence of her love and spells, she prevailed on him to remain and share her honours. In this manner seven years had been spent, when Ulysses was seized with an irresistible desire to revisit his native country. Calypso tried every expedient, and even the promise of eternal youth, to induce the hero to remain; and when all her efforts had proved unavailing, and he set sail, grief at his departure occasioned her death. (Hesiod, *Theog.* 359; Hom., *Od.* i. 50, v. 28, vii. 254; Apollod. i. 2, § 7.)

CAM, Diogo, a Portuguese discoverer, of noble birth, *belonging to the latter half of the 15th century, is famous* for having carried on, under Alphonso V., the discoveries in Western Africa commenced by Don Henry. He sailed round capes Gonçalvez and Catharina; and having obtained great influence with the king of Congo, opened up that country for the introduction of Christianity. On his first voyage (1484) he was accompanied by Martin Behem, the astronomer and cosmographer. Subsequently Cam penetrated as far as 22° S. lat.

CAMALDULIANS, Camaldunians, or Camaldolites, an order of religious persons, founded by Romuald, an Italian, in the beginning of the 11th century, in the desolate waste of Camaldoli, or Campo Malduli, on the lofty heights of the Apennines. Their rule was that of St Benedict; and their houses were never erected at less than five leagues from cities. The monks were divided into cenobites and eremites. The Camaldulians, till the close of the 11th century, were called generally Romualdins; previously, Camaldulian was a particular name for those of the desert Camaldoli. Guido Grandi (1671–1742), a Camaldulian monk, and mathematician to the grand duke of Tuscany, published *Camaldulian Dissertations*, on the origin and establishment of this order. Pope Gregory XIII. was a Camaldulian.

CAMARINA, an ancient city of Sicily, situated on the south coast, near the mouth of the Hipparis or Fiume di Camarana, as it is still called, about 20 miles E. of Gela or Terranova. It was originally founded by the Syracusans in the 6th century B.C., but was shortly afterwards destroyed by the mother city, because it had thrown off its allegiance. Restored in 495 B.C. by Hippocrates of Gela, it was again depopulated by Gelon, the conqueror of Syracuse, and did not receive a permanent establishment till 461. During the next century the mainspring of its political action was usually antipathy to Syracuse, but on the Athenian invasion it ultimately sent assistance to the beleaguered city. The Carthaginians struck a severe blow at its prosperity in the 5th century B.C., and in 258 a large part of its inhabitants were sold as slaves by the Roman consuls. The town continued to exist in the 2d century of the Christian era, and its site is still marked by a considerable mass of ruins. Μὴ κίνει

Καμάριναν, "Do not stir Kamarina," a proverb somewhat equivalent to our advice to "let well alone," is said to have been originally the answer of the Delphic oracle to the citizens when they consulted as to the draining of a neighbouring lake.

CAMBACÉRÈS, JEAN JACQUES REGIS DE (1753–1824), an eminent French statesman under the first republic and the first empire, was born at Montpellier the 18th October 1753, of an old and distinguished family. Being destined for the profession of law, he began his studies in that department at an early age, and was soon recognized as one of the ablest jurists in France. And as his legal learning was one of the main sources of his fame, so it was his chief means of rendering service to his country. Cambacérès was a decided though moderate disciple of the new principles now everywhere diffused in France, and on the assembling of the States-general in 1789 was chosen as a second representative for the nobility of the district of Montpellier. The right of Montpellier to send a second noble deputy was disputed, and Cambacérès did not sit. But he was a member of the National Convention in 1792. Foreseeing the violent courses into which the Convention should be impelled, Cambacérès, from principle as well as necessity, held aloof, and sought to avoid the perils and excesses of the time by confining himself to the neutral province of jurist and legislator. The trial of the king, however, compelled him to declare himself. In the first place, he maintained that the Convention was not competent to try the king; and when the trial had been decided on, he insisted that all latitude of defence ought to be accorded to the royal counsel. As to the sentence, he found the king guilty, and worthy of the punishment due to one who had conspired against his country; but moved for delay in the execution of it, till peace should be restored, or the French soil invaded. This moderation made Cambacérès "suspect" in the eyes of the Mountain, and he confined himself more circumspectly than ever to his proper work of revising and codifying the new laws. On the downfall of Robespierre in 1794, he was a leading man in the restoration of a milder régime. He was sometime president of the Convention, and, subsequently, president of the Committee of Public Safety, in which capacity he helped to the conclusion of peace with Prussia and Spain. Under the Directory he again fell under the suspicion of the extreme party, and was obliged to retire from the presidency of the Five Hundred, to which he had been called. He took no part in the revolution of the 18th Brumaire (9th November 1799), which overturned the Directory and set up the consulate; but Napoleon had such confidence in him that he made him second consul. This confidence Cambacérès continued to enjoy all through the consulate and the empire. On the establishment of the empire he became arch-chancellor, being life-president of the Senate, and the right-hand man of Napoleon in the civil administration generally. While loyal to his master, his influence was on the whole beneficial to France. He took an important part in the redaction of the Code Napoléon, tried to dissuade Napoleon from the murder of the Duc d'Enghien and from the disastrous campaigns of 1812 and 1813, and only gave in his adhesion to the act of abdication of 1814 when resistance was manifestly hopeless, while he resumed office with reluctance during the Hundred Days.

After the final restoration of Louis XVIII. in 1815, Cambacérès again became an object of persecution, this time as a regicide, and was obliged to retire into Belgium. A royal decree of 1818 restored him to all his civil and political rights, but he did not again emerge from private life. He died in 1824. Cambacérès was a great contrast to most of the leading men in the stormy days of the Revolution. He was moderate in his opinions and in his advocacy of them; he had a clear, penetrating and luminous understanding; and was a great master of senatorial eloquence. He had been created duke of Parma in 1808, and by this name is sometimes known in history.

CAMBALUC is the name by which, under sundry modifications, the royal city of the Great Khan became known to Europe during the Middle Ages, that city being in fact the same that we now know as Peking. The word itself represents the Mongol *Kaan-Baligh*, "the city of the khan," or emperor, the title by which Peking continues, more or less, to be known to the Mongols and other northern Asiatics.

A city occupying approximately the same site had been the capital of one of the principalities into which China was divided some centuries before the Christian era; and during the reigns of the two Tartar dynasties that immediately preceded the Mongols in Northern China, viz., that of the Khitans, and of the *Kin* or "Golden" khans, it had been one of their royal residences. Under the names of Yenking, which it received from the Khitan, and of Chungtu, which it had from the Kin, it holds a conspicuous place in the wars of Chinghiz Khan against the latter dynasty. He captured it in 1215, but it was not till 1264 that it was adopted as the imperial residence in lieu of Kara Korum in the Mongol steppes, by his grandson Kublai. The latter selected a position a few hundred yards to the N.E. of the old city of Chungtu or Yenking, where he founded the new city of *Ta-tu* ("great capital"), called by the Mongols *Taidu* or *Daitu*, but also *Kaan-baligh*; and from this time dates the use of the latter name as applied to this site.

The new city formed a rectangle, enclosed by a colossal mud-rampart, the longer sides of which ran north and south. These were each about 5⅓ English miles in length, the shorter sides 3¾, so that the circuit was upwards of 18 miles. The palace of the khan, with its gardens and lake, itself formed an inner inclosure fronting the south. There were eleven city gates, viz., three on the south side, always the formal front with the Tartars, and two on each of the other sides; and the streets ran wide and straight from gate to gate (except, of course, where interrupted by the palace-walls), forming an oblong chess-board plan.

Tatu continued to be the residence of the emperors till the fall of the Mongol power (1368). The native dynasty (Ming) which supplanted them established their residence at *Nan-king* ("South-Court"), but this proved so inconvenient that the second sovereign of the dynasty reoccupied Tatu, giving it then, for the first time, the name of *Pe-king* ("North-Court"). This was the name in common use when the Jesuits entered China towards the end of the 16th century, and began to send home accurate information about China. But it is not so now; the names in ordinary use being *King-cheng* or *King-tu*, both signifying "capital." The restoration of Cambaluc was commenced in 1409. The size of the city was diminished by the retrenchment of nearly one-third at the northern end, which brought the enceinte more nearly to a square form. And this constitutes the modern (so-called) "Tartar city" of Peking, the south front of which is identical with the south front of the city of Kublai. The walls were completed in 1437. Population gathered about the southern front, probably using the material of the old city of Yenking, and the excrescence so formed was, in 1544, enclosed by a wall, and called the "outer city." It is the same that is usually called by Europeans "the Chinese city." The ruins of the retrenched northern portion of Kublai's great rampart are still prominent along their whole extent, so that there is no room for question as to the position or true dimensions of the Cambaluc of the Middle Ages; and it is most probable, indeed it is almost a necessity, that the present palace stands on the lines of Kublai's palace.

The city, under the name of Cambaluc, was constituted into an archiepiscopal see by Pope Clement V. in 1307, in favour of the missionary Franciscan John of Montecorvino; but though some successors were nominated it seems probable that no second metropolitan ever actually occupied the seat.

Maps of the 16th and 17th centuries often show Cambaluc in an imaginary region to the north of China, a part of the misconception that has prevailed regarding Cathay (see CHINA). The name is often in popular literature written Cambalu, and is by Longfellow accented in verse *Cămbălŭ.* But this spelling originates in an accidental error in Ramusio's Italian version, which, till lately, was the chief channel through which Marco Polo's book was popularly known. The original (French) MSS. all agree with the etymology in calling it Cambaluc, which should be accented *Cămbălŭc.* (H. Y.)

CAMBAY, or KAMBAY, a town of Western India, in Guzerat, or the northern division of the province of Bombay, and forming the capital of the native state of the same name, which has an area of about 350 square miles, and a population of about 175,000. It is situated on the River Mahi, at the upper part of the Gulf of Cambay, 230 miles N. of Bombay, in 22° 18′ N. lat. and 72° 39′ E. long. It is supposed to be the *Camanes* of Ptolemy, and was formerly a very flourishing city, the seat of an extensive trade, and celebrated for its manufactures of silk, chintz, and gold stuffs; but owing principally to the gradually increasing difficulty of access by water, its commerce has long since fallen away, and the town has become poor and dilapidated. The tides rise upwards of 30 feet, and at high water ships anchor near the town. The trade is chiefly confined to the export of cotton. The town is celebrated for its agates and carnelians, which are wrought into a variety of trinkets of reputation principally in China. The houses in many instances are built of stone (a circumstance which indicates the former wealth of the city, as the material had to be brought from a very considerable distance); and a brick wall, three miles in circumference, surrounds the town, enclosing four large reservoirs of good water and three bazaars. To the south-east there are very extensive ruins of subterranean temples and other buildings half-buried in the sand by which the ancient town was overwhelmed. These temples belong to the Jains, and contain two massive statues of their deities, the one black, the other white. The principal one, as the inscription intimates, is Pariswanath, or Parswanatha, carved in the reign of the Emperor Akbar; the black one has the date of 1651 inscribed. It is supposed that Cambay about the 5th century was the capital of the Hindu emperors of Western India. In 1780 it was taken possession of by the army of General Goddard, was restored to the Mahrattas in 1783, and was afterwards ceded to the British by the Peishwa under the treaty of 1803. The nawab, who is one of the 153 feudatory princes of British India by *Sunnud* or patent, pays £5876 of annual tribute to the viceroy of India from his revenue of £35,000. His military establishment consists of 800 horse and foot, who are employed indiscriminately in revenue, police, and miscellaneous duties; and a few pieces of ordnance complete his resources.

The GULF OF CAMBAY, which is shallow and abounds in shoals and sand-banks, penetrates the coast of India for about 80 miles. It is supposed that the depth of water in this gulf has been decreasing for more than two centuries past. The tides, which are very high, run into it with amazing velocity, but at low water the bottom is left nearly dry for some distance below the latitude of the town of Cambay. It is, however, an important inlet, being the channel by which the valuable produce of central Guzerat and the British districts of Ahmedabad and Broach is exported; but the railway from Bombay to Baroda and Ahmedabad, near Cambay, is gradually attracting the trade to itself. The gulf extends between 21° and 22° 10′ N. lat., and 71° 50′ and 72° 40′ E. long.

CAMBERT, ROBERT (1628–1677), the earliest composer of French operas, was born at Paris in 1628. His master for the clavecin, and probably also for composition, was Chambonnières. He was organist of the church of St Honoré, and also held the office of musical superintendent to Queen Anne of Austria, mother of Louis XIV. His earlier works, the words of which were furnished by the Abbé Perrin, continued to be performed before the court at Vincennes, till the death of his patron Cardinal Mazarin. Displeased at his subsequent neglect, and jealous of the favour shown to Lulli, who was musical superintendent to the king, he went, in 1673, to London, where he was appointed soon after his arrival master of the band to Charles II. One at least of his operas, *Pomone*, was performed in London under his direction, but it did not suit the popular taste. His principal operatic pieces were entitled *Ariadne ou les Amours de Bacchus*, *Pomone*, and *Les Peines et les Plaisirs de l'Amour.* Cambert died in London about 1677.

CAMBODIA, more properly CAMBOJA, or KAMBOJA, a very ancient kingdom of South-eastern Asia, still subsisting in decay. As now limited the territory of Camboja forms a rough parallelogram, consisting in large part of alluvial plain, lying athwart the lower course of the Mekong or Great Camboja River, just above the Delta. The greatest length of the territory runs from W. to E., covering a little more than 3½° of longitude, viz., from about 103° E. long. to 106° 40′. The mean breadth from S. to N. is a little over 2° of latitude, extending on the western coast from 10° 30′ N. lat. to 11° 45′, and on the little known eastern frontier from about 11° 35′ to 13° 40′. On the N. it is bounded by provinces which the Siamese have wrested from Camboja; on the E. by Cochin-Chinese territory; on the S. by the Delta Provinces first taken by Cochin-China from Camboja, and then by the French from Cochin-China; on the W. by the Gulf of Siam, along which it extends for 200 miles, now its only seaboard.

Both the ethnology and the early history of Camboja partake of the obscurity that hangs over Indo-China generally. But traditions of the ancient grandeur of the kingdom are borne out by the recent exploration of numerous architectural remains of extraordinary extent and magnificence within its former limits. Some important notices are found in Chinese annals, and more information is to be expected when numerous existing inscriptions shall have been successfully interpreted.

The name given by the people of Camboja to their own race is *Khmĕr*, a name which was known and used by early Arab voyagers and geographers under the form *Kŏmâr*, and noted by them as a country famous for aloes-wood; it has, however, been imbroiled in much confusion both by them and by their commentators. There is a persistent and apparently well-founded tradition among the Khmér, that before their own immigration, as they say from the north, the *Tsiam* or *Champa* race were in possession of the soil, whilst the Khmér themselves seem to have preceded the descent of the *Thai* race, to which the people of Siam and Laos belong.

Local written legends again appear to speak of two early immigrations from Gangetic India. We know that the Pali-Buddhistical annals of Ceylon record that at the conclusion of the third great synod of the Buddhist church, held at Palibothra, in the year 302 after Buddha (corresponding, according to ordinary Cevlonese reckoning, to 241 B.C., but as corrected by Professor Max Müller to 175 B.C.), a mission was despatched to the region of

Sûvarna-Bhumi—i.e., Aurea-Regio or *Chryse;* and this record may have been the real basis of the earlier Cambojan tradition. But it must not be forgotten that in Ptolemy's map of the Indo-Chinese coast are found many Sanskrit names, indicating the existence of Hindu settlements at least as early as the 1st century of our era. The name of *Kamboja*, though in later days we find it subjected to fantastic charade-making after the Chinese fashion of etymology,[1] appears to be simply the transfer of a name famous in old Indian literature as that of a race and region on the N.W. of the Panjâb, in or near the present Chitrâl. Such transfers were common, and many survive in Indo-Chinese use or memory to this day.[2]

It is a singular circumstance that some of the Cambojan legends collected by Bastian—indications of which were also recorded by missionaries two centuries ago—bring the second Indian immigration from a western region called *Rom* or *Roma-visei*. This will be noticed again.

Like other Indo-Chinese states Camboja possesses written annals; but these do not commence till 1346 A.D. Hence they only take up the history of the kingdom when its power, and perhaps its civilization, were already past their climax.

From the Chinese annals older information is obtained. These mention, under the name of *Fu-nan*, and as early as the 12th century B.C., a kingdom embracing what afterwards became Camboja; and the Emperor Hiao-wuti of the Han dynasty is alleged to have made Funan tributary, along with adjoining countries, *circa* 125 B.C. Some two centuries later the same annals place an immigration under a foreign prince, who became the founder of a dynasty, and is perhaps to be identified with the Indian leader of the native legends. The fourth king of this dynasty—say in the latter part of the 2d century—makes extensive conquests over the adjoining kingdoms and coasts, and takes the name of *Ta-wang* ("great king"), probably a translation of the Indian title *Mahâ-râja*, which reappears some centuries later in Arab narratives as that of the King of the Isles. It is alleged, too, at this time, that the people of *Ta-tsin, i.e.*, of the Roman empire, including Western Asia, frequented the ports of Funan for trade. This circumstance is highly probable when we consider that Ptolemy attests such voyages as having been made at least *occasionally*, in the 1st or 2d century, whilst the Arab narratives show that they were habitual in the 9th.

Cambojan legend, like that of nearly all the Indo-Chinese countries, couples the introduction of Buddhism (perhaps rather its re-introduction) with the name of Buddhaghosha. However that may be, it is about the 1000th year of Buddha (*i.e.*, according to the ordinary calculation 457 A.D.), and near the date usually assigned to Buddhaghosha, that the traditions place a great king, *Phutamma Surivong, i.e.*, Padma Suryavansi; and it is at this epoch of the 5th and 6th centuries that Garnier is inclined to place the great kings, who were the founders of the older architectural monuments. Fergusson would place these several centuries later, but the whole subject of their chronology is as yet too obscure. From about this time the kingdom is known in Chinese records as *Chinla*, and to those days of splendour may be referred an old Chinese proverbial saying, "Rich as Chinla." It appears long to have ruled over the valley of the Menam (since the 14th century the seat of Siamese monarchy), and perhaps at one time to the shores of the Bay of Bengal. In the reign of Prakrama Bahu of Ceylon (1155 A.D.) we hear, in the annals of that island, of his intercourse with Camboja (*Jour. As. Soc. Bengal*, vol. xli. p. 198).

A very remarkable account of Chinla or Camboja, by an envoy sent from Peking shortly after the death of Kublaï Khan (viz., in 1295–1297), has been translated by Abel-Rémusat, and affords us a strange peep into the midst of a civilization now in the profoundest decay. The accuracy of his details regarding topography and surviving monuments of architecture attests the writer's truthfulness. The court and capital are described as very splendid, whilst (as in all Indo-Chinese countries) some traits of the deepest barbarism in manners show themselves. The kingdom possessed many fortified cities; but its power was already in decline, for it had not long before suffered from one of those invasions of the Thai which have ever since been wearing it away. Again and again such invasions and temporary occupation were repeated, especially after the foundation of the Siamese monarchy by another branch of the Thai in 1350.

The Portuguese found their way to Camboja not long after the conquest of Malacca, and the kingdom still retained a good deal of the shell of its old splendour. Yet its native force appears by this time to have been in reality almost burnt out; and towards the end of the 16th century the land swarmed with foreign adventurers, both European and Asiatic, among the latter of whom Japanese were prominent. At the instigation of some of these adventurers we find the Spanish authorities at Manilla (1594–1598) engaging in "fillibustering" expeditions to Camboja, with little result. Somewhat later the Portuguese had factories in the country, and then the Dutch (1635). Notices of English trade with Camboja appear as early as 1616. In 1641 Gerard van Wusthoff of the Dutch factory conducted a remarkable expedition up the Great River to Vienchang, the capital of one of the Laos states, about 1000 miles from the sea,—a feat never repeated till the French mission of 1866–68. In 1643 Mynheer Regemortis, envoy from Batavia, with all the Europeans of the factory, on his way to court, were assassinated under Portuguese instigation, and this put a discreditable and too characteristic end to the official relations of Europeans with Camboja. The English established a factory at Pulo Condore, a group of islands off the coast of the Cambojan delta in 1702, but this also came to a speedy end in the massacre of its members by the Macassar sepoys of the garrison. The first missionary who entered Camboja was Gaspar da Cruz, a Dominican, in 1555. He has left some curious particulars which are given by Purchas.

Camboja continued to be ground between the two millstones of Siam and the now rising kingdom of Cochin-China. The former about 1690 annexed large tracts on the N.W., augmented a century later, and again in 1810–12, by seizures which embraced the districts adjoining the Great Lake, at the very heart of the old monarchy; the latter in the middle of the last century absorbed the whole of the Delta; and Camboja was thus reduced to its present narrow limits. In 1846 a king was enthroned under the joint investiture of Siam and Cochin-China. The French invasion of the Anamite provinces in the Delta took place in 1859, and these were formally ceded in 1862. Meantime Camboja seemed about to be finally swallowed up by Siam. It was manifest, however, that the prospects of the new French possession would be materially restricted if all above the Delta were Siamese; and France began to claim the character of protector of Camboja. In 1864 the king, Morodam, was solemnly crowned in the presence of a French and of a Siamese representative; and a treaty was

---

[1] The syllables of *Kamboja* have been tortured by the later natives to mean "born of the waters," "race of Kam (Khmér)," and what not. The modern Chinese have corrupted *Kamboja* through *Kan-phu-chê* into *Tung-po-chai*, probably to meet some fancy of a similar kind.

[2] The occurrence of the name *Camboja* on one of the *repliche* of the inscriptions of Asoka, in connection with the names of regions in the extreme south of India, has lately raised a question whether the Indo-Chinese Camboja did not even then exist.

concluded, placing the kingdom formally under joint protection of those two powers, but practically of France. The presence of a Siamese resident at the court ceased; and thus a reprieve at least was given to this ancient monarchy.

Capitals and Seaports.—The ancient capital of Camboja in its splendour was *Angkor*, of which we shall speak below, abandoned in consequence of its exposure to Siamese aggression in 1388, but briefly reoccupied in 1437. In 1388 the court moved to *Basan* or *Boribun*, on the S.W. shore of the lake, and a few years later to *P'nompenh*, corruptly in some books called *Calompé*, at the confluence of the outlet of the Great Lake with the Mekong. This appears to be the place named by some of the old writers *Chordamuco*. About 1528 it was established at *Lovek* (called by Valentijn *Eauwek*), near the west side of the issue from the lake; then at *Puntenang* or *Pontaipret* opposite Lovek. Udong, a few miles north of the confluence, became the capital in 1739, and so continued down to 1866, when it was again transferred to P'nompenh. The chief port of foreign trade in the 17th century was *Potaimat*, called by foreigners *Ponteamas*, replaced afterwards by *Kangkao* or *Atien* on the same bay. But both were in the territory taken by the Cochin-Chinese, and now French. Since the annexations by Siam and Anam Camboja has only one port, *Kâmpot*. The trade is chiefly in Chinese hands. Between this and the rich alluvial tract round the capitals a high range of hills has to be passed, but there is a cart road the whole way to P'nompenh.

Chief Geographical Features.—The great river *Mekong*, known also as the Camboja River, a name bestowed when its delta yet belonged to Camboja, flows through the existing territory for about 250 miles, from N.E. to S.W. This river as a whole will be better dealt with elsewhere (see MEKONG). The next main feature of the present limited territory is the "Great Lake," as it is called by the Cochin-Chinese (*Bienhoa*), or "Freshwater Lake" of the Cambojans (*Talé-Sab*),—by the Malays styled the Lake of Sri Râma. This lake is of the nature of those sheets of water which in Bengal are called *jhîls*, viz., a shallow depression in an alluvial plain, retaining a part of the annual overflow of the rivers throughout the year, and hence subject to great variations in depth and extent. In the rains it is said to have a length of about 100 miles (N.W. to S.E.) with a breadth of one-third as much. Its average depth in the dry season is only 4 feet. The Udong River, communicating between the lake and the Mekong, fills a channel of great breadth. Its waters change their direction half-yearly, from June to December filling the lake from the Mekong, and from December to June draining the lake into the Mekong. The lake is an object of superstitious regard to the people, and the fishery therein is the most important event in their annual life. It is carried on in the dry season, during which time extensive pile-villages are erected in the lake, where the drying and salting of the fish is carried on. The dried fish is exported largely to Cochin-China, as well as live fish in cages. Much also is converted into oil.

Natural Productions and Exports.—The *elephant* may be regarded as the characteristic animal of Camboja. Wild herds are numerous, and frequent the shores of the lake in the dry season. The tamed animals are by no means so well trained as in India, but they are the chief beasts of burden, and a few years ago did not cost more than £10 or £12. The *rhinoceros* also abounds (the species we do not find stated) about the foot of the mountains north of the lake. Strong and handsome *ponies* are bred, much in demand at Bangkok. Among wild animals there are said to be three species of *wild cattle*.

The Chinese envoy of 1295-97 mentions among Cambojan exports rhinoceros' horns, gamboge, cardamoms, and eagle-wood; and these are still among the most characteristic. Though the gum called *gamboge* derives its name from Camboja, and is chiefly supplied by that country, the tree (*Garcinia Morella*) does not appear to have been seen in its native localities by any botanist. Dr Thorel, of the French expedition, indicates its habitat as in the N.W. of the old Cambojan territory, about Korat, now subject to Siam. The *cardamoms* (*Amomum villosum*, Louveiro) are produced in the mountains not far from the lake. *Eagle-wood* (or *Aloes-wood*) appears to be the result of disease, forming internal cavities in the soft white wood of *Aquilaria agallocha*, and is obtained by splitting the tree,—its probable existence in any tree being recognized by indications known to the collectors. It is now found chiefly near the coast of the Gulf of Siam, about Chantibun (now Siamese), and is said to be common in the island of Kotran, or Phukok, off Kampot. The names *eagle-wood*, *agila*, &c., are corruptions from the Sanskrit *Aguru*, and have nothing to do with eagles.

Other vegetable products are nutmeg, liquorice, caoutchouc and gutta-percha, tobacco, sapan-wood, pepper, rice, cotton, &c., with benzoin from the Upper Mekong. Additional exports of sorts are hides and horns, tortoise-shell, lac, ivory, and dried elephant flesh. Iron of excellent quality is smelted and wrought by some of the hill tribes.

People, Government, and Language.—Of the numerous wild, or we should rather say *illiterate*, tribes on the borders of the Cambojan plain, and still imperfectly known, we cannot speak in our limited space. The Cambojans proper, or *Khmër*, differ much from both Siamese and Cochin-Chinese. They are described as tall, well and strongly made, showing less of Mongoloid feature than any of the better known nations of Indo-China; good-natured but apathetic, and leaving all the trouble and gains of trade to Chinese, Anamites, and Malays. Their religion is Buddhism of the usual Indo-Chinese type. But like the other races of that region they call in the devil-dancing medicine-man in illness. They cut the hair short, leaving a top-tuft, and wear the *langûti*, or loin-cloth, tucked between the legs, using that Hindu name for it.

There are some 2000 Roman Catholic Christians in the country, and some considerable number of Malay and Tsiam Mahometans. The Malays are chiefly on the coast, and claim to be very ancient settlers.

The government is an absolute monarchy, after the usual Indo-Chinese kind, with a second king or cæsar, the *Yuva-râja* of ancient India, known by a corruption of that title.

The language is placed by the late Mr Logan in his "Mon-Anam" class. But it appears to differ materially from the Anamite, as well as from other purely monosyllabic languages of Indo-China. These, like the Chinese, employ a variety of so-called *tones*, or inflexions of voice, by which different meanings of the same monosyllable are discriminated,—the Anamite having six such tones. The Cambojan is without these, being spoken, as a missionary expresses it, *recto tono*. The numeration is stated by Garnier to present traces of a quinary system, but the vocabulary which he gives hardly confirms this. The letters are an ornamental form of the Pali, which has been the foundation of all the Indo-Chinese alphabets. An older form, illegible to the modern priests, is used in the inscriptions.

Architectural Antiquities. As already indicated, there are of the highest importance and interest. They are found in some forty or more known localities, and some as far north as Suren in the Korat district, now Siamese (14° 47′ N. lat.) Indeed the most important remains are all in what is now Siamese territory, north of the Great Lake. The remains embrace walled cities of large extent; palaces and temples, stupendous in scale and rich in design, and often most elaborately decorated with long galleries of

storied bas-reliefs; artificial lakes enclosed by walls of cut stone; stone bridges of extraordinary design and excellent execution; elaborate embanked highways across the alluvial flats, &c. Were it possible to reconcile the geography, they would almost justify the extravagant fictions of Mendez Pinto regarding the palaces and temples of Timplan and Timagogo.

About fifteen miles north of the lake, buried in forest, is the ancient capital, commonly called *Angkor* or *Nakhon* (both corruptions of the Indian *Nagara*) *Thom*, or "the Great City," the proper old name of which was *Inthapataburi*, *i.e.*, Indraprasthapuri, after the capital of the Pandus in the ancient India of the Mahâbhârat. Mouhot and Thomson have by some misapprehension greatly exaggerated its size; but its walls do in fact form a quadrangle of nearly 8½ miles in circuit and 30 feet in height, surrounded by a very wide ditch. There are five gates (two on the east), of very grandiose though fantastic architecture. About five miles south of the city is the great temple called *Nakhon Wat*, *i.e.*, "the city monastery," one of the most extraordinary architectural relics in the world.

This also is enclosed by a quadrangular wall of 3860 yards in compass, outside of which is a wide ditch. We cannot attempt to describe this edifice with its corridors, sculptures, and towers rising to 180 feet and upwards. Much in the detail is Indian; much that is but obscurely traced as yet in India connects itself with other remains in Indo-China and in Java; much again is unique. One remarkable point is the *Roman-Doric* character of the enriched pilasters which form a feature frequently recurring; this, too, has parallels, though not quite so striking, in Ceylon and in mediæval Burmese remains.

Some remarkable features of the Camboja monuments are distinctly mentioned in the Chinese mediæval narrative, but there is apparently no notice of the Nakhon Wat. If force is to be attached to this omission, it will indicate the date of that building as between 1296 and 1352, the date of the first great Siamese invasion. We are not yet in a position to say with certainty to what worship they were dedicated, though inclining to the view of Garnier, who regards them as belonging to Buddhism, the still existing worship of the nation; and *some* of the temples are certainly Buddhist. Mr Fergusson dissents, and regards the great temples as monuments of serpent-worship,—though admitting doubt.

Though the existence of these remarkable ruins had been quite forgotten till what may be called their rediscovery, of which the first distinct account was given by M. Mouhot in 1859, they had been known to some of the early Jesuit missionaries, who speak of their "discovery in 1570;" and a notice of them from such a source will be found in Zedler's *Universal Lexicon* under "Cambodscha" (1733). Father Ribadeneyra (1601) says a legend ascribed the erection to Alexander the Great. This must have originated with the Malays, among whom Iskandar and the "Alexander Saga" were familiar and popular. And to the same communication may perhaps be due that strange introduction of *Rome* into the legendary history. This would then be Rome in its Mussulman sense,—*Rûm*—*i.e.*, Greece or Turkey.

Thomson; *Antiquities of Cambodia*, by J. Thomson; Fergusson's *Hist. of Architecture*, vol. ii., and *Tree and Serpent Worship*; Crawfurd's *Mission to Siam and Cochin-China*; Abel-Rémusat, *Nouv. Melanges Asiat.* vol. i. 100; *Calendar of State-Papers, East Indies*, 1862; Purchas, vol. iii., &c. (H. Y.)

CAMBORNE, a small town in the county of Cornwall, about 13 miles by rail S.W. of Truro. It is a neatly-built place, and stands in the immediate neighbourhood of some of the most productive tin and copper mines in the county, which afford employment to most of the inhabitants. It has a handsome parish church, in the later Gothic style, restored in 1862. Population in 1871, 7757.

CAMBRAY, in German Kamerik, or Kambryk, a fortified town of France, in the department of Nord situated on the right bank of the Scheldt, 32 miles S. of Lille, in 50° 10′ N. lat. and 3° 14′ E. long. It is well built, contains a large number of ancient gabled houses, and is surrounded by strong walls flanked with round towers. The principal building is the Cathedral of St Sepulchre, occupying the site of an earlier structure, which was greatly damaged during the French Revolution, and suffered still more severely from a conflagration in 1859. It still contains a monument by David to the memory of Fénelon, but the tomb in which the archbishop was buried was broken open in 1793, and his coffin melted into bullets. Of the old archiepiscopal palace the only thing left is a Renaissance portal; and the archbishop now has his residence in what was formerly the convent of the Benedictines. Besides these may be mentioned the church of St Gery, and the belfry of St Martin; the town-house, dating from 1873; the citadel; and the public library, containing upwards of 35,000 volumes, in what was formerly the church of the hospital of St John. Cambray is the chief town of an arrondissement, and has judicial and commercial tribunals of the first instance. A college, two theological seminaries, a medical school, and a school of design are its chief educational establishments; it has also various learned societies. The town has long been famous for its manufacture of fine muslin, to which it gave the name Cambric; and it also contains manufactories of cotton cloth, lace, and thread, as well as sugar-factories, oil refineries, distilleries, breweries, and other industrial establishments. Its trade consists of grain, wine, hemp, hops, cattle, butter, and coal. The Scheldt begins to be navigable at the town, and communicates with St Quentin by means of a canal. Population in 1872, 22,897.

Cambray is the ancient Nervian town of *Camaracum*, which is first mentioned in the Antonine Itinerary. In the 5th century it was the capital of the Frankish king Ragnachar. Fortified by Charlemagne, it was captured and pillaged by the Normans in 870, and unsuccessfully besieged by the Hungarians in 953. During the 10th, 11th, and 12th centuries it was the scene of frequent hostilities between the bishop and his supporters on the one hand and the citizens on the other; but the latter ultimately effected their independence. In 1478 Louis XI., who had obtained possession of the town on the death of the last duke of Burgundy, handed it over to the emperor, and in the 16th century Charles the Fifth caused it to be fortified with a strong citadel, for the erection of which the castles of Cavillers, Escaudœuvres, and many others were demolished. From that date to the peace of Nimeguen, which assigned it to France, it frequently passed from hand to hand by capture or treaty. In 1793 it was besieged in vain by the Austrians. The League of Cambray is the name given to the alliance of Pope Julius II., Louis XII., Maximilian I., and Ferdinand the Catholic against the Venetians in 1508; and the Peace of Cambray, or as it is also called, the Ladies' Peace, was concluded in the town by Louise of Savoy, mother of Francis I., and Margaret of Austria, aunt of Charles V., in name of these monarchs. The bishopric of Cambray dates from the 5th century, and it was erected in 1559 into an archbishopric, which continued till the Revolution, and has since been restored. The bishops received the title of count from the Emperor Henry I., and in 1510 were raised to the dignity of dukes, their territory including, besides the town itself, the district called Cambresis.

CAMBRIDGE, COUNTY OF, one of the smaller English counties, belonging to the South Midland division of England, is about 45 miles in length and 30 in breadth. It comprises 17 hundreds, and the boroughs of Cambridge and Wisbeach. There are in the county, which is embraced within the diocese of Ely, 172 parishes and townships, besides parts of parishes. It contains, according to the census of 1871, 524,926 statute acres. It is divided by the old course of the River Ouse into Cambridge proper and the

Isle of Ely. Until the year 1857 the Isle of Ely was practically a county palatine, like the county palatine of Chester and the bishopric of Durham, a distinct enclosure within the county. The liberty of the Isle of Ely has its court of quarter sessions, a separate commission of the peace, and its own county rate. The county, which is purely agricultural, and for the most part arable, presents a vast land expanse, with little that is picturesque and with no claims to fine scenery, but imposing to the summer tourist by the frequent pollarded watercourses, the heavy crops of grain, and the immense dome of sky.

Cambridgeshire evidently once formed part of the country of the Iceni. The Icenhilde, always a British way, and never a via strata, was most probably derived from the same root. The country is rich in Roman roads and other remains, and some of the Roman roads were doubtless formed on old British tracks. (For the ancient roads consult Professor Babington's *Monograph.*) Cambridgeshire became a dependency of the kingdom of East Anglia. It was included in the Danelagh, though how far it was colonized by Northmen is uncertain. According to Henry of Huntingdon, in the war against the Danes, when the English fled the men of Cambridgeshire resisted most manfully. During the period of the Conquest, the siege and capture of the Isle of Ely is the most remarkable event; the sea country was the last that yielded to the Conqueror, and the half-legendary Hereward is the last English hero of the conflict. In the time of Stephen, in the time of John, and in the time of the Barons' War in the reign of Henry III., the Isle of Ely emerges repeatedly into notice. The splendid foundations of Etheldreda and her sister, with the rising colleges of the university of Cambridge, drew pilgrims to the district from all parts of the country. In the Civil War Cambridgeshire belonged to the associated counties, and had no actual share in the conflict. Cromwell possessed a considerable estate in the Isle of Ely, and lived in the rectory house of Ely till elected member for Cambridge. He became governor of Ely, and his son Henry died in the neighbourhood (Carlyle's *Cromwell*). King Charles, after his seizure at Holdenby, was brought to Childerly near Cambridge, and was taken thence to Newmarket, near which the Parliamentary army was encamped under Fairfax and Cromwell.

The drainage of the Cambridgeshire fens forms one of the most remarkable chapters of the industrial history of the country. All the northern portion of the county, at the junction of the counties of Lincoln, Huntingdon, Cambridge, and Norfolk, is part of the vast district known as the Great Level of the Fens. A large province of 680,000 acres of the richest land in England has been reclaimed from the sea and preserved by continual watchfulness, as completely as is the case in the opposite kingdom of Holland. The great works which have reclaimed the land were mainly due to Cornelius Vermuyden, the Dutchman, knighted by Charles I., and the Dutch and Flemings he employed, and in more recent times to James Rennie, the eminent engineer. The chief promoters were five successive earls of Bedford, who have given their name to the great Bedford Level. From the earliest times, however, there had been conflicts between the encroaching waters and the inhabitants of the invaded shores. The Romans, who left few great works unattempted, reclaimed much of the rich silt and soil deposited on the shores of the Wash, and constructed the immense drainage work known as the Carr (Fen) Dyke. They also carried causeways over the fen country. Much of the Roman work seems to have lapsed into the "great dismal swamp," caused by the silting up of the outfalls of rivers, and the mingling of the tides with the upland waters. The submerged territory seems originally to have been rich meadow and forest land, and it receives the river deposits of soil from eight counties, the causes of the great and abiding fertility. All this region then formed an immense estuary, the Wash, or rather a large lake, communicating by shifting channels with the sea. The more elevated grounds were called islands, whose isolation sometimes invited the founders of religious edifices, and sometimes those without the pale of the law. The whole country from Cambridge to Lincoln was a morass abounding with fish and fowl, and all the scattered habitations of the fenmen were liable to be swept away by sudden storms.

The monasteries and the bishops of Ely did good work in the reclamation of lands. Morton's Leam was a canal made by Bishop Morton of forty miles from Peterborough to the sea, which drained the North Level. After the dissolution of the monasteries the work fell into abeyance until renewed by Cornelius Vermuyden. The fenmen vehemently opposed his plans, and Oliver Cromwell, the member for Cambridge, put himself at their head and succeeded in stopping all the operations. When he became protector, however, he sanctioned Vermuyden's plans, and Scotch prisoners taken at Dunbar, and Dutch prisoners taken by Blake in his victory over Van Tromp, were employed as the workers. Much valuable land was reclaimed, and the fen country altogether improved. There remained, however, very much to be done. Vermuyden's system was exclusively Dutch; and while perfectly suited to Holland it did not meet all the necessities of East Anglia. He confined his attention almost exclusively to the inland draining and embankments, and did not provide sufficient out-let for the waters themselves into the sea. So late as 1810 there were districts in which people reaped their harvest, and gathered their orchard fruits, and went to church, in boats. Rennie pointed out the true scientific principle that a thorough drainage could only be effected by cutting down the outfalls to low water at spring tides, and so facilitating the escape of the waters. He projected a great system of drainage and provided a more effectual outfall of the Ouse into the Wash. His work was improved and extended by Telford.

Throughout the present century great improvements of all kinds have been carried on. The surplus waters were formerly pumped into the rivers and canals by *windmills*; but this could not be counted on as an invariable force, and steam-mills are generally substituted. Dykes, causeways, sluices, and drains were now cut in every direction. All the rivers of Cambridgeshire which formerly found their outlet at Wisbeach, before the channel was choked up, now mainly by cuts and straightenings, have forsaken their old beds and are poured into the sea by artificial streams, like the Bedford rivers into the German Ocean.

It will be interesting to enumerate the original courses of the streams; it is not always easy to decipher the natural channels. The chief rivers are the Nene and the Ouse, with its tributary streams. The Nene on arriving at Peterborough turned to the right, and making a circuit of several meres passed by March to Wisbeach. It is now made to flow into three channels. One arm is the Catswater or Shire Drain, which meets Morton Leam and flows into the Wash; the second arm is Whittlesey Dyke, or the old Nene river; the third is Morton's Leam. The Great Ouse enters the Fens near Earith, where it formerly forked; one branch ultimately joined the Nene; the other branch was called the West Water, and ultimately joined the main channel of the Nene. Both the channels are now nearly closed to the waters of the Ouse, and are carried by the Bedford rivers in a direct line to Denver, where they meet the channel of the Little Ouse, and so

reach the sea at King's Lynn. The Cam or Granta, formed by the junction of some small Essex streams, flows N.N.E. from Cambridge, changing its name to Ouse three miles from Ely, but instead of flowing into the sea at Wisbeach is carried on to Denver and thence to the sea at Lynn. The Lark for seven miles separates Cambridgeshire from Suffolk, and the Linnet, a feeder of the Lark, also serves as a boundary stream for another stretch of seven miles.

All the northern part of Cambridgeshire, the fen country, is covered with alluvial deposits resting on a bed of clay of great but unknown thickness. These are called the Kimmeridge and Oxford clays, the Oxford clay lying below the Kimmeridge. There is no break of continuity between them; they are only distinguished by the embodied fossils above the clay. There is a deposit of peat of variable thickness, but generally very deep. South and east the Fens are bordered by a narrow belt of Kimmeridge clay, beyond which is a strip of lower and then of upper greensand; and beyond this, in the southern division of the country, we have the chalk. In the fen country there are great masses of gravel, sand, and drift-clay. "We can trace the rise of the fen lands through the deposits of land-floods, and the growth of fuel-bogs" (Professor Sedgwick). Besides these regular formations and deposits Cambridgeshire contains much diluvial deposit, not to be accounted for by land-floods or tides and currents, but belonging to the glacial period. The uplands or so-called "highlands" of Cambridgeshire are level, but broken by low chalk hills in the neighbourhood of Essex and Suffolk. The chalk is in two divisions,—upper with flints, lower without flints. At the foot of the hills the lower bed of chalk has been extensively quarried, and much elaborate sculpture in Ely Cathedral has been formed of it. The thin upper greensand below the lower chalk rests on gault. This formation everywhere constitutes the northern border of the chalk, and in the western portion of the country forms rich, well-wooded soil. The gault is the blue brick earth of Cambridge, and has a thickness of 150 feet. Professor Sedgwick has given a careful account of the fossils found in these formations, and there is an ample collection of examples in the Woodwardian Museum. In deep diggings in the fen lands, and in excavations for buildings in Cambridge gravel, remains are discovered of the wolf, bear, horse, and *bos primigenius*. Diluvial beds of loam mixed with fragments of chalk extend into the parts of Cambridgeshire adjacent to Essex and Suffolk. Along the irregular line separating Cambridgeshire from these counties the iron-sand which underlies the gault rises to the surface. It forms excellent garden ground, and is rich in fragments of mineralized wood (Conybeare and Phillip's *Geology of England and Wales*). Cambridgeshire is one of the chief corn-producing counties. A part of the county near the south-west border was formerly called the Dairies; and large dairy farms are still found producing cheese very similar to the best Stilton. The census of 1871 returned 25 per cent. of the male population as agricultural labourers, farm-servants, and shepherds. Although the county is entirely agricultural, mainly arable, with some wheat and pasture crops, many busy trades are also carried on,—brewing and malting, brick-making, lime-burning. There is a great deal of boat-building, and there are many seamen employed on the navigable cuts. The climate of the county is generally healthy, but it would be premature to say that ague is altogether banished from the fen country.

Some reference has already been made to the British and Roman antiquities. There are some remains of Roman camps; a few only of Norman castles. In the southern part of the county are four great dykes. They once formed the boundary between East Anglia and Mercia; each extended from fen land to wooded country, crossing the open intervening space. The chief of these fosses was the Devil's Ditch; another was the Fleam or Balsham Dyke; the others were the ditches of Breat and Bran. All these were most probably of British origin. The county of Cambridge is rich in churches, especially in Ely and Cambridge and their neighbourhoods. We have abundant examples of Pre-Norman, Norman, Early English, Decorated, Perpendicular. At Ely there are some valuable monastic remains. The famous Abbey of Thorney is only represented by various foundations, and a fragment of the abbey church, which has been worked into the present parish church. Of domestic architecture there are very slight remains in one or two manor houses, and some remains of the Episcopal palace at Downham. The modern architectural efforts may well compete with those of any former age.

Though Cambridge is the county town, Ely is the one city of Cambridgeshire. It derived its name from the abundance of the eels which were found there. It was situated on the largest of the islands that rose above the level of the Fens, which in winter were surrounded by water, and were only accessible by certain passes or gates. (See ELY.) The other Cambridgeshire towns are soon enumerated. Wisbeach (beach of the Ouse) is a large and prosperous town, next in size and population to Cambridge. The navigable River Nene intersects the town and makes it a port. The main export is grain; the main import is Baltic timber. The Wisbeach canal gives water communication in many directions. Newmarket has a somewhat peculiar reputation, and is called the metropolis of the turf. The race course is four miles in length, of elastic turf; some hundred horses may be seen exercising on the Downs. There are seven race meetings in the year. This and the neighbouring town of Royston, on the borders of Hertfordshire, have been often frequented by royalty; many houses are inhabited by patrons of the turf. Our literature abounds with references to Newmarket, which, truth to say, are as a rule of an unflattering description. Wimpole Park, Lord Hardwicke's place, is the principal seat in the county, and the fine park has some of the best timber in the country. Wimpole is celebrated for its pictures, and there is a good library. The principal other proprietors are the dukes of Bedford and Rutland and Mr Childers. Doddington was till recently the richest living in England, but the revenues are now spread over seven rectories. The village of Babrahan is celebrated as the first place in England where water irrigation was introduced, and also for the breed of Southdown sheep which bears the name. Whittlesea Mere is the most remarkable of the modern reclamation; there abundant crops are raised where boating and fishing were carried on within living memory. Whittlesea West is still covered with water many months in the year, when there is abundance of waterfowl. The ancient town of March should be noticed, also Chatteris, Thorney, Johan, formerly famous for their abbeys. The town of Thorney was greatly improved and beautified by a former duke of Bedford. In 1875 the county was under the ownership of 6497 proprietors of one acre and upwards, and of 6677 proprietors of less than one acre. For parliamentary purposes the two divisions of the shire and isle form one district, returning three members to parliament. The population of the county in 1861, as compared with 1851, exhibited a decrease of 5 per cent., but in 1871 an improvement was manifested to the extent of 6 per cent. The rate of progress is slow, and it is hardly likely to be accelerated. By the census of 1871 the population consisted of 186,906 persons,—of whom 92,115 were males, and 94,791 females. (F. A.)

CAMBRIDGE, the chief town of the above county, and the seat of a famous university, is situated on the Cam, in

the midst of a healthy fertile country, which for the most part has been reclaimed from the fens. The trade of the town is derived from its being the centre of an agricultural district, and from the custom of the resident members of the university. The Cam changes its name to the Ouse as the Isis does to the Thames, and Cambridge is the head of navigation for barges from King's Lynn, which before the railways was connected with a very considerable business. Cambridge is now a chief station on the Great Eastern line, and is also connected with the Great Northern, the London and the North-Western, and the Midland lines. A large market is held on Saturdays. The town has returned two members since the time of Edward I. It is a very ancient corporation, and under the Municipal Reform Act is governed by a mayor, ten aldermen, and thirty common councilmen The university, a corporation separate from

Plan of Cambridge.

the borough, also returns two members. The town has an excellent free grammar school, founded by Dr Perse, good public institutions, and endowed alms-houses. The town owes its existence mainly to the university, which overshadows it in importance. In this respect Cambridge and Oxford differ from all other universities, which are generally absorbed in the town in which they are situated. Cambridge, like Oxford, is of a singularly unique character, and affords examples of architecture from the dawnings of authentic history to the more modern structures designed to meet the wants of our own day. The original Cambridge was the ancient Roman *Camboritum*, a small settlement on the left or north bank of the Cam or Granta. A castle was built to overawe the fen country, of which some ruins may be traced, and Roman coins from the time of Vespasian downwards have been found. In Anglo Saxon times the river was called Granta, and the Roman town Grantchester, a name which still survives in the present village near the town. The modern name was derived from a great stone bridge, the only one in those parts that was thrown across the Cam, probably in old Roman days. Bede gives Cambridge or Grantchester the epithet of "desolate." It was exposed to the assaults of the Danes and repeatedly plundered. In the days of Edward the Elder we find that Grantbridge, a derivation of Cambridge, is giving its name to a shire, in a new division of Mercia. In the 11th century the borough began to expand beyond the narrow Roman limits. A population grew up by degrees on the other side of the river. Religious foundations gradually took their place in the borough. We begin to have authentic annals in the 12th century. Learned men came hither anxious to teach, and scholars anxious to be taught. The students first lived in the houses of the townsfolk, as in German and Scottish universities; we afterwards find hostels, where students and teachers lodged together. It is probable that the great Benedictine monasteries of the Fens may have had a part in the origin of the university. We find Henry III. (1231) issuing writs for the regulation of Cambridge "clerks," and making mention of chancellor and masters. A few years later we find the king entrenching the town with two gates, which, however, were burnt by the barons. In Wat Tyler's insurrection the colleges were attacked and ransacked by the rabble, it was supposed with the connivance and assistance of the Cambridge townsfolk, but were repulsed by the young bishop of Norwich. The first two Stuart kings and the first two Hanoverian kings cultivated friendly personal relations with the university. In the Civil War many of the colleges sent their plate to King Charles, but town and university without actual conflict came into the obedience of the Commonwealth. In other respects Cambridge has been so fortunate as hardly to possess any history.

We proceed to notice somewhat in detail the remarkable structures which have now a European reputation. Although there is no street to equal the glorious High Street of Oxford, yet the long street which begins with the Trumpington Road, and then as a narrow lane fronts Sepulchre Church, is lined with the most important colleges. What is called "the backs of colleges," where the Cam wanders beneath frequent arches through groves and gardens, has a more unique beauty than Oxford or any other university town can display. Within recent years there have been constant changes at Cambridge, and the aspect of the place has been materially altered; there have been great demolitions and reconstructions, and some very fine edifices have been added. The Fitzwilliam Museum, as we first enter Trumpington Street, is a very striking edifice, and as large funds from time to time are accumulated for its extension, it will become increasingly valuable. Recently it has at a great expense received a remarkable amount of colour and decoration. The columned façade, with its portico and colonnades, is considered by some the most striking piece of architecture in the kingdom. It was the foundation of Viscount Fitzwilliam, an Irish peer, who bequeathed to the university his picture gallery, including fine examples of the greatest masters, 120 folio volumes of engravings, a valuable library, and £100,000. Various other valuable collections have from time to time been gathered into the Fitzwilliam Museum. The sculpture gallery is peculiarly rich There are also Colonel Leake's Greek vases, the Disney marbles, the Ellison collection of modern painters, the Mesmer collection. At a short distance from the Fitzwilliam, at the end of a water-course, is Hobson's Conduit, removed here from the market-place, where it stood from 1614 to 1856. Hobson was a great benefactor to Cambridge, and is commemorated by Milton. The Pitt Press is found in this line of street, with a very church-like appearance. It was erected in memory of William Pitt the statesman. Addenbrooke Hospital, the Botanic Garden (arranged after De Candolle's system), the Anatomical Museum, and the Observatory, are very much worthy of examination. The renowned Senate-house, the centre of the university, is remarkable for its elaborate finish and perfect proportions,

In this fine room the university examinations are held and degrees are bestowed. The scenes witnessed here when the mathematical honour list is issued, and on the degree day following, are a very interesting episode of university life. The senior wrangler of the year receives a mighty ovation. Very near the Senate-house is the University Library; the Georges were great benefactors to both. It is one of the few libraries entitled to copies of all new books. The number of books and MSS. is about half a million. The most remarkable MS. is that known to scholars as D, the *Codex Bezæ*, the uncial MS. or vellum of the four Gospels and the Acts, presented by Theodore Beza. The front of the library is an Italian balustraded arcade; the basement story of the quadrangle is called "the Schools," a much more limited expression than the same Oxford term. In the "school" were once carried on the lectures and disputations from which "wranglers" and "sophs" derived their names. One part of the schools is devoted to the Woodwardian or Geological Museum, enriched by the collections of the late Professor Sedgwick. He taught geology to undergraduates in visiting the neighbourhood with them. Close to this is the Mineralogical Museum, enriched with diamonds presented by the late Lord Alford. The fine new buildings of the Union Society are noticeable. Various Cambridge churches are very interesting. The Round Church or Sepulchre Church is one of four similar churches in England (the Temple Church being one), modelled after the Church of the Holy Sepulchre at Jerusalem. It was restored in 1841 by the Camden Society. Great St Mary's, like St Mary's, Oxford, is the church of the university. St Benedict (or Benet) Church is very interesting. Its restoration in 1869 fully displayed the magnificent Romanesque arch of great antiquity, and traces of Early English and Pre-Norman remains. St Mary's the Less, next to Peterhouse, is a very ancient church. The old church of All Saints, opposite St John's, has been removed, and is rebuilt in Jesus Lane. There are a large number of modern churches. There is a wide market-place and several open spaces, such as Christ's Piece and Parker's Piece. The railway station, where different companies find a common home, is spacious and handsome. The so-called school of Pythagoras (the origin of the term is obscure) was doubtless the abode of a Thegn or Saxon gentleman. The mound of the Castle, a natural hill scarped and cut down, must have been of great importance in overlooking the fen country. It was probably within the lines of the Roman station, and a castle was built here by the Conqueror; many houses, according to *Domesday Book*, being removed to make way for it. Edward I. lodged here, but the castle was soon in ruins. The massive gateway was removed to make way for the county courts. The county gaol, at the rear of the county court, was arranged according to plans of John Howard the philanthropist.

Each college in Cambridge has its separate interest,—something remarkable in chapel, hall, or library, in garden or gallery. We shall rapidly indicate some distinctive features in each. The largest of the colleges is Trinity, the largest collegiate foundation in Europe. It is on both sides the street, for a new court, the Master's Court, was built at the expense of Dr Whewell, and his cipher, W.W., is on the capacious tower. The King's Gateway is the entrance to this famous college. The great canopied statue is that of Henry VIII., in whose time this vast portal was built by the scholars of Trinity. We pass into the great court with its velvet sward and the lofty stone conduit, known as Nevill's Fountain. On one side is the Master's Lodge, with a fine collection of portraits, and a set of state rooms. On the same side is the lofty Gothic hall, with a high-peaked Flemish roof. In term time when the great hall, with its painted glass and armorial bearings, is crowded with students, the sight is remarkable enough. On entering the chapel the ante-chapel should be carefully noted, with the statue of Newton in a sitting posture, the statue of Barrow, a statue of Macaulay, and soon there will be one of Whewell. A second great gateway, with the niched statue of Edward III., leads into the second court. On the south is a third gateway with four towers on the angles, called, from a statue of Queen Elizabeth in her robes, the Queen's Gateway. The library was begun by Barrow and designed by Wren. It is the most classic building in the university—in Wren's favourite style of the old Italian. It overlooks the river, and below the library is a colonnade opening on the bridge and the Lime Walk. In the value of its contents this library ranks next to the university library; it possesses the mathematical MSS. of Newton and the poetical MSS. of Milton. It numbers nearly 100,000 volumes. The woodwork is by Gibbons; the series of marble busts by Roubillac. Recent additions have been made of the busts of Professor Sedgwick, Mr Tennyson, and Mr Ellis. At the end of the room is Thorwaldsen's statue of Lord Byron, which was refused admission into Westminster Abbey.

St John's.

The next largest college is St John's, which is famous for its series of splendid improvements. The college consists of four courts; the plain brick edifices are carried to the brink of the river, but on the other side of the river is the magnificent New Court designed by Rickman, the finest modern structure of all the Cambridge quadrangles. The massive antique gateway of the first court has the armorial bearings of the foundress of this college and Christ's College, the Lady Margaret, countess of Richmond and mother of Henry VII. The chapel and hall are in the front court. The second court is still larger, and is one of the very few untouched by modern restoration. The third court has a cloister on the west; and the antique library, unaltered for generations, takes up the whole upper part of the north side. The Master's Lodge, finished in 1865 by Sir G. G. Scott, extends westward. A light Gothic bridge over the Cam conducts into the New Court, a stately quadrangle, with a vaulted cloister along the south side. The magnificent chapel, erected mainly by the society, and enriched with many gifts, at great expense, was opened in 1869. It was erected by Sir G. G. Scott, and has some resemblance to the Sainte Chapelle at Paris. The roof and painted glass are especially remarkable. Chantrey's monument to Henry Kirke-White, erected at the expense of an American gentleman, is to be transferred to this chapel.

St Peter's.

St Peter's College, or Peterhouse, is the oldest of the colleges. It was founded in 1257 by Hugh de Balsham, who was one of the first to separate between the monkish and scholastic element in education. The university long gave special honour and celebration to De Balsham. St Peter's is remarkable for eminent men, and for lay fellowships at a time when they were hardly known elsewhere. The gardens are good, and there is a small deer park.

King's.

King's College owns that magnificent chapel which widely dominates over all the buildings in the town and university. The college was originally commenced and endowed by Henry VI., in connection with Eton. Henry VII. deserves the title of a second founder. The chapel is one vast long-drawn nave. It is the latest and most sumptuous example of the Perpendicular order of Gothic architecture. The fretted roof, unsustained by a single pillar, is vaulted into twelve divisions. The centre of each is a pendant keystone, terminating alternately in roses and portcullises, each keystone weighing more than a ton. Over the stone roof is the timber roof. An organ separates between chapel and ante-chapel. The painted glass is the most remarkable that has been bequeathed to us by the age of Henry VII. and Henry VIII., and belongs to a time when the art of

painting had attained its highest excellence. There are five-and-twenty windows, with more than a hundred subjects. The chantries are fine. The exterior of the chapel, though very fine, hardly corresponds with the interior. The immense design for the college, entertained by Henry VI., has never been carried out, and the new buildings, erected at a great expense, have not been subordinated to the general design. The best of these is the Master's Lodge; the Fellows' Buildings are incongruous. King's College Chapel is certainly the architectural gem of the university.

Caius (pronounced Key's) College, in point of size, is the third college in the university. It has a somewhat special character, being termed the Medical College. The founder was a physician high in favour with Philip and Mary. His tomb, with the inscription "Fui Caius," is the great ornament of the chapel. In the painted glass of the chapel is a series delineating the miracles of healing. No college has undergone greater alterations within recent years than Caius College, the larger part of the college having been taken down and rebuilt. It has now some of the most striking architectural effects in modern Cambridge. The three famous gates—the Gate of Humility, the Gate of Virtue, the Gate of Honour—are retained. Mr Fergusson says of the last "that it is one of the most pleasing as well as one of the most advanced specimens of the Early Renaissance in England." The new hall is by Salvin (1864). The little college of Trinity Hall has also a special character, being the Legal College. To a great extent it has been rebuilt, after a destructive fire in 1851. The gardens are very fine.

Queens' College is the work of the two rival queens of the Red Rose and the White, Margaret of Anjou and Elizabeth Woodville, who are always regarded as co-foundresses. Erasmus took up his abode here and promoted the new learning. His study is supposed to have been in the south-west tower of the old court. The chapel has been beautifully restored in recent years. A quaint bridge, called the "mathematical bridge," leads into the garden or wilderness on the other side of the Cam. On the south side of the Cloister Court is Erasmus's Court. It is said to be in contemplation to fill up the western side with a new river front. Corpus Christi College has an imposing frontage, not unlike that of Christ Church, Oxford, though on a smaller scale. This college has the credit of having begun the series of reconstructions which has been in progress for years past up to the present time. The college is in intimate relations with the town of Cambridge, in which it has much property, and from which it has derived various benefactions. On the north end of the great quadrangle is the Old Court, which is said to retain more of its original features than any other court in the university. Archbishop Parker lent his library to this college on condition that if twenty-five books should ever be missing the bequest should devolve to Caius College. Opposite Corpus Christi is the college long known as Catherine's Hall, the only hall in Cambridge, but in the unfulfilled expectation of many private halls being established now termed a college. It is extremely picturesque, with a side of the principal quadrangle planted with elms and open to Trumpington Street. It might almost be called the Theological College, as it has produced an extraordinary number of ecclesiastical writers. Clare College consists of a single court, and is remarkable for its finished beauty, with "more purity and grace than any other example which can be named" (Fergusson). The bridge, avenue, and lawn are noticeable. This college is supposed to be Chaucer's "Soler Hall at Cantabrage." Once one of the largest, it is now one of the smallest colleges. Here "Ignoramus" was acted before the delighted James I.

Emmanuel College has a peculiar interest of its own. Once its site was occupied by a house of Dominican friars, and it subsequently became the chosen college of the Puritans. The frontage of this college is long and imposing. Through an arcade we pass into the principal court, above an arcaded side of which is a picture gallery designed by Wren for the Master's Lodge. The library here is very good. Sidney Sussex College has a history very parallel to that of Emmanuel College. They were together styled in the time of Charles I. "nurseries of Puritanism." Oliver Cromwell was a member of this college, and the best extant likeness of him is to be found here. There is also *Bernini's* bust from the plaster impression taken after death. This college was improved to the extent of entire obliteration by Wyatville, who has only left the old oriels of the Master's Lodge remaining. The lodge has a large pleasure garden attached. Next to this college is Christ's, opposite to which a street runs westward that has some curious old houses and an old name, Petty Cury, the meaning of which has been much discussed; it most probably means "little cookery." Christ's College was the foundation of the Lady Margaret, the saintly foundress of St John's. Her portrait is in chapel and hall, and her arms over the gateway. Like Sidney Sussex, Christ's was restored in the last century, and nearly all traces of antiquity extinguished. Christ's is famous for its associations with the Platonists, and especially with Milton. His rooms are pointed out, and his mulberry tree in the garden has drawn pilgrims from every part of the world. The old tree is carefully propped up and mounded, and a new tree has been planted from an offshoot. Behind the college is an open space of park-like character leading down to the boats. Some of the latest restorations now in progress are in Pembroke. When Queen Elizabeth saw this college she exclaimed, "Oh domus antiqua et religiosa!" but the peculiar features which give this college its picturesque appearance are being inexorably sacrificed to modern requirements. The chapel was designed by Sir Christopher Wren, and executed at the cost of his uncle, Bishop Wren, as a thank-offering for his liberation from a confinement of eighteen years in the Tower. The college has been called "Collegium Episcopale," from the number of its prelates. It also boasts the great names of Edmund Spenser, Gray, and William Pitt. Jesus College stands pleasantly back from the public road, surrounded with gardens and meadows. The ivied walls have a very pleasant aspect. The college chapel is a very noble one, and may rank after King's College chapel and the new chapel of St John's. It is among the most magnificent of the recent restorations at Cambridge. It is part of the old church of St Rhadegund; the ante-chapel, which is being decorated under the care of Mr Rossetti, being portion of the original nave. The New Court or Garden Court is shadowed with trees of many years' growth. The college has recently laid out fresh grounds and buildings. The cock, the badge or *rebus* of Bishop Alcock, the founder, is discernible in many parts of the college. Magdalene College is the only college on the north side of the Cam. It was founded by a lord of Audley End, whose representative always nominates the head of the college. It boasts three libraries,—the college library, the Peckard library, and the Pepysian library. The last contains the Pepy's MS. and much old black-letter literature. The last of the Cambridge colleges is Downing College. It was only founded in the year 1800, with large bequests from a Cambridgeshire baronet. The first undergraduate was in 1821, but the college has in later years received a considerable development. The well-wooded grounds are handsome and extensive, and are thrown freely open to the public.

Some of the Cambridge localities should be mentioned. The suburb of Barnwell has the remains of an ancient

priory. At Stourbridge is the disused chapel of an ancient hospital for lepers. The greatest fair in England was one held here. The little village of Trumpington is a favourite locality. Granchester has some remains which make it a question whether it or Cambridge Castle was the site of the old Roman station. Byron's Pool is in the river here. Madingley is a fine old mansion, the residence of the Prince of Wales when at Cambridge, and possibly the scene of Gray's *Elegy*. Between this place and Cambridge is the Observatory. The central dome revolves on wheels, and can be moved by a single hand. The remarkable telescope was presented by the late duke of Northumberland in 1835. A favourite walk is to the very moderate elevation known as the Gogmagog Hills, an off-shoot of the chalk range, the summit of which has been a Roman camp and a lord-treasurer's abode. The Ladies' College at Girton may also be mentioned. Chesterton and Cherry Hinton are familiar resorts of Cambridge men. These are environs of Cambridge. The borough population of Cambridge in 1871 was 30,078, consisting of 13,742 males and 16,286 females. (F. A.)

CAMBRIDGE, a city of the United States, in the county of Middlesex, Massachusetts. It lies on Charles River, three miles N.W. of Boston, with which it is connected by two bridges, with long causeways, and by horse railroads, or tramways It is the seat of Harvard University, the oldest, richest, and most thoroughly equipped literary institution in the United States. Connected with the university is an observatory, in 42° 22′ 48″ N. lat. and 71° 8′ W. long. Under the name of Newtown a settlement was made on its territory, then much more extended than at present, by some of the first company of English colonists on Massachusetts Bay in 1630. It was then proposed to make it the capital of the colony; but the neighbouring peninsula of Boston was found more convenient for commerce and defence against the Indians. The order of the colony court in 1636 having provided for planting a college at Newtown, its name was changed to Cambridge, in honour of the English university town, where some of the leading men of the colony had been educated. The first company of settlers, being Mr Hooker's church and congregation, moved to Connecticut in 1636, to find better farm-land. Their rights were purchased by another body of colonists just arrived from England. The present site of the college halls was originally "fortified" by palisades, within which the settlers found protection at night for themselves and their cattle against a possible inroad of the savages. Here was set up the first printing-press in the United States, and from it issued John Eliot's translation of the Bible, for the Indians, in their own language. Under the title of "Cambridge Farms," the present town of Lexington, incorporated as such in 1712, was a part of the original town. The town of Brighton, now annexed to the city of Boston, formerly South Cambridge, or Little Cambridge, was separated and received its present name in 1807; and the west part of the original settlement, known as Menotomy, was marked off in the same year, as West Cambridge, now known as Arlington. Between this place and Cambridge is North Cambridge; and the districts of the city nearest to Boston, by the two bridges, are called Cambridge Port and East Cambridge. Cambridge was incorporated as a city in 1846. It is for the most part level, with much marsh land near the river, portions of which are in process of being reclaimed. The cemetery of Mount Auburn is on the western border of the city. The population of Cambridge in 1874 was 50,337; the numbers of polls for voters, 11,983; of dwellings, 7383. The valuation was—of personal property, $17,532,971; of real, $49,013,700; total, $66,576,671. The net debt of the city incurred for water-works, streets, school-houses and other improvements, is $3,792,135. The city appropriation for 1874 was $2,771,508. Total cost of the water-works, $1,399,396. The police department, with 60 officers, cost $71,710; fire department, $97,355; filling up low lands, $650,000. The average number of paupers, 129; net cost of their maintenance, $38,000. Cost of street lighting, $20,157. The system of public schools is very complete and efficient, including a high school, 7 grammar schools, 18 primaries, and a training school,—with 183 teachers; cost of maintenance, $260,187·47. Cambridge was the site of the camp of the first American army, at the outbreak of the War of the Revolution with Great Britain. From it went the detachment which intrenched on Bunker's Hill; and here Washington took command of the army, July 3, 1775.

CAMBYSES, a Persian royal name, derived from the Greek Καμβύσης, in which form it appears in Herodotus and in the Greek writers generally. In inscriptions from Egypt the name is given as Καμβύσαις (Letronne, *Recueil d. inscrip. grecq.*, ii. pp. 350, 356, *f.*). In the old-Persian of the Behistun inscription it stands in the form *Kabujiya* (Rawlinson) or *Kambujiya* (Oppert, Spiegel). In Zend the name takes the form *Kavaus*, and in Arabic and modern Persian it is worn down still further to *Kavus* and *Kaus*. In Egyptian the name occurs under three forms of transcription,—*Kanbuza*, *Kembatet* (Lepsius, *Königsbuch*, taf. xlix.), or rather *Kambuzia*, and *Kambunsa* (Lauth, *Ein neuer Kambyses-text*, p. 5). The etymology of the name is obscure, and the attempts to explain it by Rawlinson (*Jour. As. Soc.*, xi. p. 97) and Benfey (*Die persischen Keilinschriften*, p. 77) cannot be regarded as successful. It has been often remarked that the name, or one very similar, occurs more than once in the East as an ethnical and geographical designation. Thus we find Camboja a territory in India, Kamoj a tribe of the Kafirs in Cabul; and a territory named Cambysene, situated in the north on the Kur, is known to Greek geographers. In the same region there was a river called Cambyses, the modern Jora. Perhaps with Spiegel (*Eranische Alterthumskunde*, vol. ii. p. 294) we may regard the personal name Kambujiya as originally an adjective, meaning belonging to Kambuja. In Egypt, also, Cambysu occurs in the *Itinerarium* as the name of a place in the Delta, but this is probably derived from the Persian king about to be mentioned, by whom Egypt was conquered

The persons known by the name of Cambyses belong to the Achæmenian line of Persian kings. It is thought that the great-grandfather of Cyrus the Great was thus called. The evidence, however, for the existence of this Cambyses, though strong, is constructive rather than direct (see Rawlinson's *Herodotus*, vol. iv. p. 259). It is certain that the father of Cyrus was named Cambyses. He is called by Herodotus (i. 107) "a Persian of good family," but by Xenophon (*Cyrop.*, i. 11, 1) he is denominated "king of the Persians." The justness of this title is proved by an inscription on a brick found at Senkereh, in which Cyrus calls himself "the son of Cambyses, the powerful king," as well as by the statement of Darius Hystaspis, in the Behistun inscription (col. i. 4), that eight of his Achæmenian ancestors had been kings. During the reign of this Cambyses the Persian nation was included in the Median empire, and he is represented as the vassal of the Median king Astyages. At the same time he is said to have married Mandane, the daughter of Astyages, by whom he became the father of Cyrus. Such, at least, is the account of Herodotus, Xenophon, Diodorus, and Trogus Pompeius. Ctesias and Nicolaus Damascenus give a different representation.

It is stated by Loftus (*Chaldæa and Susiana*, p. 224) that he found at Warka "bricks inscribed in slightly

relieved cuneiform characters of Cambyses, the brother of Cyrus, a personage of whom we possess no historical notice whatsoever."

The only other, and the best known, king of this name is the elder son and successor of Cyrus, who reigned over the Persian empire, according to Herodotus, for seven years and five months—from 529 to 521 B.C. Of his proceedings before his famous invasion of Egypt little is known. To this period we must now, on the authority of the Behistun inscription (i. 10), in opposition to Herodotus (iii. 30), assign the secret murder of his brother, Bardiya (the Smerdis, Merdis, Mardus, or Mergis of the Greeks,—called Tanyoxarces by Ctesias, and Tanyoxares by Xenophon). Egypt at this time lay on the borders of the Persian empire; its subjugation had long been an object of ambition to the great Asiatic conquerors; it had recently provoked reprisals from Persia by sending help to Lydia against Cyrus; and in resolving to attack that country Cambyses was both carrying out the settled policy of his predecessors and accomplishing the purpose of his own father. If therefore, as is not unlikely, there was such an occasion given for the enterprise as that which Herodotus relates, it is not necessary to suppose that this was more than a pretext. A year or two were spent in collecting the forces of the empire, and the preparatory measures taken seem to have been marked by prudence and skill. A fleet of Phœnician and Greek ships was collected to operate against the vessels of the Egyptians; and the help of an Arabian chief was secured to provide water for the army in crossing the desert on the south and west of Palestine. The old king of Egypt, Amasis, under whom the country had enjoyed a long period of peace and prosperity, died a few months before the invasion, and was succeeded by his son Psammenitus, under whom the measures of defence proved unsuccessful. An obstinately contested but decisive victory was gained by the Persian arms near Pelusium, and this was speedily followed up by the siege and capture of the capital, Memphis, and by the subjugation of the whole country. The date of this conquest is commonly regarded as 525 B.C. (see Rawlinson, *Anc. Mon.*, vol. i. p. 385), though some find cause to place it one or even two years earlier (*cf.* v. Gumpach, *Zeitrechnung d. Ass. u. Bab.*, pp. 165, *f.*; Lauth, *op. cit.*, pp. 13, *f.*; Brugsch, *Hist. d'Égypte*, i. p. 267; Duncker, *Gesch. d. Alterthums*, vol. ii. p. 792, *n.*; Lepsius, *Königsbuch*, p. 89).

Henceforward the life and activity of Cambyses centred in his new dominion. We know from an important hieroglyphic inscription proceeding from a priest of Neith at Sais, that he assumed the responsibilities and titles proper to a king of Egypt, taking as his throne-name that of Ramesut. Moreover, it is evident that for a time at least he cultivated the good-will of his new subjects. We learn that he took Egyptians who had been officers of Psammenitus into his immediate service; that he sought instruction in regard to the rites of their religion, and was initiated into certain of its mysteries; that he listened to complaints in regard to the profanation of the temples by Persian and other foreign soldiers, and gave orders for their removal from the sacred precincts; that he secured the priests in the receipt of the temple-revenues, and arranged for the due and continued celebration of the customary ceremonies and festivals. A monument is still extant on which he is represented adoring, on bended knee, the god Apis. (See De Rougé, *Mémoire sur la statue naophore du Vatican*, passim: Brugsch, *op. cit.*, vol. i. pp. 266, *f.*; Lauth, *op. cit.*, pp. 17, *f.*) One act, indeed, of a different complexion is reported by Herodotus (iii. 16), viz., his outraging and finally consuming by fire the embalmed body of Amasis,—an act, the historian assures us, which shocked the feelings alike of Egyptians and of Persians, and which strongly attests the same jealous and resentful temper which prompted the murder of his brother.

After having established himself in his new possession, Cambyses, Herodotus (iii. 17, *f.*) informs us, planned three expeditions. One was against Carthage, in regard to which, however, he was thwarted by the refusal of his Phœnician mariners, who formed the principal portion of his sea-forces, to operate against their kindred. Another was directed against the Oasis and temple of Jupiter Ammon in the desert west of Egypt (see Heeren, *D. afrikan. Völker*, i. p. 416), the issue of which was that the whole of the force sent on this enterprise, numbering, it is said, 50,000 men, perished in the sand. The third was intended for the subjugation of the Ethiopians on the south of Egypt (regarding whose locality see Heeren, *op. cit.*, i. pp. 337, *f.*; Rawlinson, *Herod.*, vol. ii. p. 421; Maspero, *Histoire ancienne*, pp. 533, *f.*), and of this Cambyses himself took the command. The army, however, had marched less than a fifth of the distance when their provisions failed, and they were reduced to the utmost straits,—even, it is said, to cannibalism. Cambyses was thus forced to retrace his steps and to lead back the remnant of his army to Egypt in disappointment and disgrace.

Under the smart of this threefold discomfiture the conduct of Cambyses towards the Egyptians assumed a new and much more stern and cruel aspect. The people of Memphis were rejoicing on occasion of the discovery of a calf bearing the marks of their god Apis, when he arrived there on his return from his unfortunate expedition. Irritated by their apparent lack of sympathy, and misconstruing their joy, he ordered some of the magistrates of the city to be put to death; and what was still more fatal to his popularity, he commanded the newly-found god to be led into his presence, and inflicted upon it with his dagger a mortal wound. The epitaph of this unfortunate god "has been found by M. Mariette in the Serapeum, and is now in the museum of the Louvre" (Lenormant, *Manual of Anc. Hist.*, vol. ii. p. 99). We hear also of his violating the sepulchres of the Egyptians, and of his penetrating into the sanctuaries of their gods, and making sport of the more grotesque images. According to Herodotus, it seemed to the Egyptians that he had gone mad; and it is certain that they retained the most gloomy recollections of this period of their history. In the inscription already mentioned, drawn up while the Persians were still supreme in the country, and therefore with due reserve and caution, reference is made to the procedure of Cambyses in such language as the following:—"There happened a calamity in this district along with the very great calamity which befell the whole land;" "a frightful misfortune befell Egypt, the like of which never occurred in this land" (Brugsch, *op. cit.*, i. p. 271; Lauth, *op. cit.*, p. 19, *cf.* p. 49). It is, in all probability, the sense of this "frightful misfortune"—the keenness of feeling excited by the outrageous deeds of Cambyses towards their gods—which led the Egyptians to allege that he was smitten with frenzy, and to put in circulation some at least of the many stories relating to his cruelty towards his own countrymen and relatives which Herodotus and others report.

After an absence from Persia of several years, Cambyses, having appointed Aryandes, a Persian, governor of Egypt, set out on his homeward march. He was met, according to Herodotus (iii. 64), at a place in Syria called Agbatana, supposed by some to be Batanaea or Bashan, by others to be Hamath, by the tidings of the Median revolution, the usurpation of the sovereignty by Gomates, the Magian, and the impersonation by the usurper of his own brother whom, as has been noticed, he had caused to be secretly murdered. Springing hastily upon his horse, his sword fell from the sheath and wounded him mortally in the thigh. According

to Ctesias (*Exc. Pers.*, § 12) he died at Babylon, of a wound accidentally inflicted while carving a piece of wood for his amusement These accounts agree in representing his death as accidental A somewhat different impression is conveyed by the statement of Darius on the point in the Behistun inscription (i. 11), who says that "killing himself he died' (*Cf.* Oppert, *Les inscriptions des Achéménides*, p. 54.) It may be, as Spiegel believes (*Eran. Alterthum.*, ii. p. 302), that the phrase expresses nothing more than the Greek tradition reports. Rawlinson, however (*Anc. Mon.*, iv. p. 394), and Duncker (*op. cit.*, ii. p. 801) understand it as meaning that he committed suicide. The character of this king is sufficiently obvious. It is evident that he was an impulsive, self-willed, reckless, ambitious despot, of the peculiarly Oriental type, possessed of considerable ability as a general, but with passions so strong and uncontrolled as to render the powers he possessed worthless for good. It was reported that from his childhood he was liable to epilepsy and also, what is probably more trustworthy, that he came to be much given to wine. By the Egyptians he made himself utterly abhorred. By the Persians also, while they acknowledged his success in enlarging their empire, his memory was held in evil repute. While they called Cyrus a father, they called his son a despot or master; and while they said the one was "gentle, and procured them all manner of goods," they called the other "harsh and reckless" (see Herodotus, iii. 33, 34, 89). In the Hebrew Scriptures, Cambyses appears once under the name of Ahasuerus, in Ezra iv. 6 (see ARTAXERXES). Some suppose that he is the "cruel lord" and "fierce king," to whose hands the Egyptians were to be given over, according to Isa. xix. 4 His name occurs in Babylonian contract-tablets found at Warka, with the title "Cambyses, king of Babylon." (See Loftus, *op. cit.*, p. 222; Bosanquet, *Trans. Bib. Archæology*, i. pp. 210, *f.*) He is usually regarded as the Lohrasp of Persian traditional history (Malcom, *Hist. of Persia*, i. p. 334); but another of the heroes of that cycle of romance, Kaus, appears both from the name and from the exploits ascribed to him to be the true representative of Cambyses. (*Cf.* Spiegel, *op. cit.*, vol. i. p. 594; Gobineau, *Hist. des Perses*, vol. i. p. 523.) (W. TU.)

CAMDEN (1), a city of the United States, capital of Camden county, New Jersey, situated on the left bank of the Delaware River, directly opposite Philadelphia, with which it is connected by a regular steam-boat service. It lies 87 miles S.W. of New York, and is the terminus of several railway lines. Among its public buildings the chief place is held by the court-house and the railway stations; and its principal industrial establishments are iron-foundries, saw-mills, chemical works, glass-works, shipyards, and engineering factories. The city received its charter in 1831; and gas-light was first introduced in 1852. In 1840 the population was only 3371; in 1850 it amounted to 9479, and in 1870 to 20,045.

CAMDEN (2), the capital of Kershaw county in South Carolina, United States, 33 miles N.E. of Columbia on the Wateree River, which is navigable for steam-boats as far as the town. It contains an arsenal, an academy, and a library, and is altogether a flourishing little town. It is best known as the scene of two battles,—the first fought in 1780 between Gates and Cornwallis, and the second in 1781 between Greene and Rawdon. Population in 1870, 1007.

CAMDEN, WILLIAM (1551–1623), a celebrated antiquary and historian, was born in London, May 2, 1551. His father, who was a native of Lichfield, settled in London, where he became a member of the company of paper-stainers. His mother was of the ancient family of Curwen of Workington in Cumberland. Young Camden received his early education at Christ's Hospital and St Paul's School; and in 1566 he entered as a servitor of Magdalen College, Oxford; but not succeeding in getting a demi's place, he removed to Broadgate Hall, and, somewhat more than two years afterwards, to Christ Church, where he was supported by his friend and patron Dr Thornton. About this time he became a candidate for a fellowship at All Souls College, which he lost through the adverse influence of the Roman Catholic party. In 1570 he supplicated the regents of the university to be admitted bachelor of arts, but in this also he was disappointed. The following year Camden came to London, where he prosecuted his favourite study of antiquity, under the patronage of Dr Goodman, dean of Westminster, by whose interest he was made, in 1575, second master of Westminster school. From the time of his leaving the university to this period, he had travelled through great part of England, with a view to make observations and collect materials for his *Britannia*, on which he was now seriously engaged. In 1581 he became intimately acquainted with the learned President Brisson, who was then in England, and in 1586 he published the first edition of the *Britannia*, a survey of the British isles, written in elegant Latin. In 1593 he succeeded to the head mastership of Westminster school, on the resignation of Dr Grant. In this office he continued till 1597, when he was promoted to be Clarencieux king-at-arms. In 1600 Camden made a tour to the north, as far as Carlisle, accompanied by his friend Mr (afterwards Sir Robert) Cotton. In 1606 he began his correspondence with the celebrated President de Thou, which continued to the death of that historian. In the following year he published his last edition of the *Britannia*, from which the several English translations have been made; and in 1608 he began to digest his materials for a history of the reign of Queen Elizabeth. In 1609, after recovering from a dangerous illness, he retired to Chiselhurst in Kent, where he continued to spend the summer months during the remainder of his life. The first part of his annals of the queen did not appear till 1615, and he determined that the second volume should not appear till after his death. The work was entirely finished in 1617, and from that time he was principally employed in collecting materials for the further improvement of his *Britannia*. In 1622, being now upwards of seventy, he determined to lose no time in executing his design of founding a history lecture in the university of Oxford. His deed of gift was accordingly transmitted by his friend Mr Heather to Mr Gregory Wheare, who was by himself appointed the first professor. Camden died at Chiselhurst, Nov. 9, 1623, in the seventy-third year of his age, and was buried with great solemnity in Westminster Abbey, where a monument was erected to his memory. He was a man of great modesty and integrity, profoundly learned in the history and antiquities of England, and a judicious and conscientious historian. The Camden Society, founded in 1838 for historical research, was so named in honour of him. Besides the works already mentioned, he was author of an excellent Greek grammar, and of several tracts in Hearne's collection. His greatest and most useful work is the *Britannia*. It was first translated into English, and published in folio in London in 1611, by Dr Philemon Holland, who is thought to have consulted the author himself; and therefore great respect has been paid to his additions and explanations, on the supposition that they may belong to Camden. But in a later edition of the same translation, published in 1636, the doctor has taken liberties which cannot be excused. A new translation, made with the utmost fidelity from the last edition, was published in 1695, by Edmund Gibson of Queen's College, Oxford, afterwards bishop of London; in which, besides the addition of notes, and of all that deserved to be taken notice of in Dr Holland's first edition, there are many other augmentations

and improvements, all properly distinguished from the genuine work of the author.

Gibson's edition was reprinted in 1722, and several times subsequently. The latest and best editions are those by Gough, 1789-90, 3 vols. fol., and by Gough and Nichols, 1806, 4 vols. fol.

CAMDEN, CHARLES PRATT, EARL, AND VISCOUNT BAYHAM (1713-1794), chief-justice of the Common Pleas, lord chancellor of England, and president of the council, was born in 1713. He was a descendant of an old Devonshire family of high standing, the third son of Sir John Pratt, chief-justice of the King's Bench in the reign of George I. He received his early education at Eton College, whence he passed, at the age of seventeen, to King's College, Cambridge. In 1734 he became a fellow of his college, and in the following year obtained his degree of B.A. Having adopted his father's profession, he had entered the Middle Temple in 1728, and ten years later he was called to the bar. He practised at first in the courts of Common Law, travelling also the western circuit. In 1740 he took his degree of M.A. For some years his practice was so limited, and he became so much discouraged, that he seriously thought of turning his back on the law and entering the church. He listened, however, to the advice of his friend Sir Robert Henley, a brother barrister, afterwards known as Lord Chancellor Northington, and persevered, working on and waiting for the success which in such case is usually slow to come. The first case which brought him prominently into notice and gave him assurance of ultimate success was the Government prosecution, in 1752, of a bookseller, William Owen, for a libel on the House of Commons. Pratt was engaged as junior counsel for the defence, and he made his mark in an earnest and powerful speech, which contributed to the verdict for the defendant. In 1753 he undertook the defence of Murphy, who stood charged with the forgery of a will. Four years later, through the influence of William Pitt (afterwards earl of Chatham), with whom he had formed an intimate friendship while at Eton, he received the appointment of attorney-general. The same year he entered the House of Commons as member for the small borough of Downton in Wiltshire, which was subsequently disfranchised. He sat in parliament four years, but did not distinguish himself as a debater. His professional practice now largely increased. One of the most noticeable incidents of his tenure of office as attorney-general was the prosecution of Dr Shebbeare, a violent party writer of the day, for a libel against the Government contained in his notorious *Letters to the People of England*, which were published in the years 1756-1758. As a proof of Pratt's moderation in a period of passionate party warfare and frequent "State Trials," it is noted that this was the only official prosecution for libel which he set on foot. In January 1762 Pratt was raised to the bench as chief-justice of the Common Pleas, this post being vacant by the death of Chief-Justice Willes. He was at the same time knighted. Soon after his elevation the nation was thrown into great excitement about the prosecution of the "worthless profligate" John Wilkes, and the question involved in it of the legality of "general warrants." Chief-Justice Pratt pronounced, with decisive and almost passionate energy, against their legality, thus giving voice to the strong feeling of the nation, and winning for himself an extraordinary degree of popularity as one of the "maintainers of English constitutional liberty." Honours fell thick upon him in the form of addresses from the city of London and many large towns, and of presentations of freedom from various corporate bodies. In July 1765 he was raised to the peerage as Baron Camden, of Camden Place, in the county of Kent; and in the following year he was removed from the court of Common Pleas to take his seat as lord chancellor (July 30, 1766). This seat he retained less than four years; for although he discharged its duties in so efficient a manner that, with one exception, his decisions were never reversed on appeal, he took up a position of such uncompromising hostility to the Governments of the day, the Grafton and North administrations, on the greatest and most exciting matters, the treatment of the American colonies and the proceedings against John Wilkes, that the Government had no choice but to require of him the surrender of the great seal. He retired from the Court of Chancery in January 1770, but he continued to take a warm interest in the political affairs and discussions of the time. In his speeches in the House of Lords he sometimes showed a strong ill-feeling against his great opponent, Lord Mansfield, on the doctrine of libel. He continued steadfastly to oppose the taxation of the American colonists, and signed, in 1778, the protest of the Lords in favour of an address to the king on the subject of the manifesto of the American commissioners. In 1782 he was appointed president of the council under the Rockingham administration, but retired in the following year. Within a few months he was reinstated in this office under the Pitt administration, and held it till his death. Lord Camden was a strenuous opponent of Mr Fox's India Bill, took an animated part in the debates on important public matters till within two years of his death, introduced in 1786 the scheme of a regency on occasion of the king's insanity, and to the last zealously defended his early views on the functions of juries, especially of their right to decide on all questions of libel. He was raised to the dignity of an earl in May 1786, and was at the same time created Viscount Bayham. Earl Camden died in London, April 18, 1794. His remains were interred in Seale church in Kent.

CAMEL, the *Djemal* of the Arabs and *Gamal* of the Hebrews, a genus of Ruminant Mammals, which, with the South American llamas, form the family *Camelidæ*, and which in their dentition, in the absence of horns and of hoofs completely enveloping the toes, and in the separation of the navicular and cuboid bones of the tarsus, show an affinity with certain of the Perissodactyle *Ungulata*. In common with the llamas, and unlike all other ruminants, the camel has two upper incisor teeth, conical and laterally compressed, and somewhat resembling canine teeth, of which in the upper jaw there are two, in addition to twelve molars. Beneath there are six incisors, two canines, and ten molar teeth, the whole forming a dentition admirably suited for the tearing asunder and mastication of the coarse dry shrubs on which the camel usually feeds. It possesses besides many other peculiarities in form and structure specially adapted to its mode of life. Its nostrils are in the form of oblique slits, which can be opened or shut at will, and thus the organ of smell, which in the camel is of extraordinary acuteness, is preserved from contact with the hot acrid sand that, like a "pillar of cloud," frequently sweeps across the desert. The extremities only of the two toes which form the foot are free, and are each terminated by a short and somewhat curved nail, the rest of the toes being connected together by means of a broad elastic pad on which the foot rests, and which buoys the camel up as it moves on the soft and ever-shifting surface. The horny callosities on the breast and limb-joints, on which the camel rests when being loaded, may possibly have resulted from the long ages of servitude to which it has been subjected, but whether they existed in the wild camel or not, traces of them are said to be now found on the new-born young. The hump or humps on the camel's back are mere masses of fat, without any corresponding curve on the vertebral column of the animal, and form a reserve of nourishment to be used when other supplies fail; consequently during lengthened periods of privation, and during the rutting season, when the males almost cease to eat, these masses greatly diminish in size. The camel

driver knows well the value of this natural storehouse, and takes care before starting on a lengthened journey to have the humps of his beasts well distended. In its native deserts, however, the camel is more liable to suffer from lack of water than of food, and accordingly the stomach is so modified as to allow of a certain quantity of water being stored for future use. On the walls of the paunch or first stomach, little pouches with narrow mouths are developed; these are the so called "water cells," the biggest of which in an adult camel measures when dilated about three inches in width and depth, and these serve to strain off a considerable quantity of water from the contents of the paunch, retaining it for future use by means of powerful sphincter muscles. The upper divided lip of the camel is slightly extensile, and is used as a feeler with which to touch and examine its food before turning the same into its mouth. The animal is further characterized externally by its long neck, the dusky colour of its fur, the shaggy masses of long woolly hair on certain parts of its body, and the disproportionate shortness of its legs. These, together with the peculiarities already mentioned, combine to make it one of the most ungainly of known animals, and almost justify the recent description given of it by Dr Russell, the *Times* correspondent, as "an abominably ugly necessary animal." Nevertheless, it is as indispensable where great deserts are to be traversed as is the ship on the ocean highway, and this fact seems to have completely blinded the Arab to its undoubted deficiences in form, for in his poetry allusion is sometimes made to the motions of the camel as to a recognized standard of elegance.

The camel is one of the oldest mammals now living, and fossil remains have been found in the Miocene of the Sevalik Hills of a species (*Camelus sivalensis*) somewhat larger, but otherwise scarcely distinguishable from recent forms. "The difference is so slight," says Andrew Murray, "it pleases us to think that we may have here, in this most ancient animal, a species which saw the Miocene epoch, and which has survived all the chances and changes which have taken place since then." That it was one of the earliest of domesticated animals is evident from the frequent allusions made to it in the oldest written records of the human race Six thousand camels are said to have formed part of the wealth of the patriarch Job; they also formed part of the present which Pharaoh gave to Abraham, and it was to a company of Ishmaelites travelling from Gilead to Egypt on camels, laden with spices, much as their Arabian descendants do at the present day, that Joseph was sold by his brethren. Naturalists are able to indicate with more or less certainty the wild progenitors of most of the domestic animals, but they have hitherto failed to obtain any reliable evidence of the existence, at the present day, of the wild ancestor of the camel. In the eastern hemisphere it stands alone, sole representative of the family to which it belongs, its only allies, the llamas, being confined to the slopes of the Andes and the southern parts of South America. Palæontologists, however, by the discovery of several fossil forms, have been able to bridge over the geographical gap which at present separates the two branches of the Camelidæ.

During the rutting season the male camel becomes exceedingly savage and dangerous, and engages in fierce contests with its fellows The gravid female carries her young for fully eleven months, and produces only one calf at a time, which she suckles for a year. Eight days after birth the Arabian camel stands three feet high, but it does not reach its full growth till its sixteenth or seventeenth year. It lives from forty to fifty years. The flesh of the young camel resembles veal, and is a favourite food of the Arabs, while camel's milk forms an excellent and highly nutritious beverage, although, according to Layard, it does not furnish butter. The woolly hair, which grows to a great length on the under side of the neck, the upper part of the legs, and on the humps, is shorn every summer, and is woven into a variety of stuffs used by the Arab for clothing himself and his family, and in covering his tent. It was in raiment of camel's hair that John the Baptist appeared as a preacher. The hair imported into this country is chiefly used in the manufacture of small brushes used by painters, while the thick hide is formed into a very durable leather. The dung is used as fuel, and from the incinerated remains of this sal-ammoniac is extracted, which was at one time largely exported from Egypt.

But it is as "the ship of the desert," without which vast tracts of the earth's surface would probably have remained for ever unexplored, that the camel is chiefly valuable. In its fourth year its training as a beast of burden begins, when it is taught to kneel down and to rise at a given signal, and is gradually accustomed to bear increasing loads. These vary in weight from 500 to 1000 lb, according to the variety of camel employed, for of the Arabian camel there are almost as many breeds as there are of the horse in more temperate regions. When crossing a desert the camels are expected to carry their load 25 miles a day for three days without drink, getting a supply of water, however, on the fourth; but the fleeter varieties will carry their rider and a bag of water 50 miles a day for five days without drinking. When too heavily laden the camel refuses to rise, but on the march it is exceedingly patient under its burden, only yielding beneath it to die; relieved from its load it does not, like other animals, seek the shade, even when that is to be found, but prefers to kneel beside its burden in the broad glare of the sun, seeming to luxuriate in the burning sand. When overtaken by the deadly simoom it falls on its knees, and stretching its snake-like neck along the sand, closes its nostrils, and remains thus motionless till the atmosphere clears; and in this position it affords some shelter to its driver, who, wrapping his face in his mantle, crouches behind his beast. Of still greater service is it, when, the whole caravan being on the point of perishing for want of water, the acute sense of smell which the camel possesses enables it to perceive the presence of water more than a mile off; then it will break its halter and make an unerring track for the well. The food of the camel consists chiefly of the leaves of trees, shrubs, and dry hard vegetables, which it is enabled to tear down and masticate by means of its upper incisors and powerful canine teeth. It is, however, fond of luxurious living when such is to be had, and, according to Sir Samuel Baker, when it arrives in good pasture, after several days of sharp desert marching, it often dies in a few hours of inflammation caused by repletion; but when other animals are starving, the camel, according to the same authority, thrives "on the ends of barren leafless twigs, the dried sticks of certain shrubs, and the tough dry paper-like substance of the dome palm, about as succulent a breakfast as would be a green umbrella and a *Times* newspaper." The docility of the camel has become well-nigh proverbial throughout Europe, but recent travellers who have studied the animal in Arabia and Africa have said much to lessen, if not to extinguish, its reputation in this particular. "If docile means stupid," says Palgrave, who had ample opportunity of observing the camel during his romantic sojourn in Arabia, "well and good; in such a case the camel is the very model of docility. But if the epithet is intended to designate an animal that takes an interest in its rider so far as a beast can, that in some way understands his intentions, or shares them in a subordinate fashion, that obeys from a sort of submissive or half-fellow-feeling with his master, like the horse or elephant, then I say that the camel is by no means docile—very much the contrary. He takes no heed of his rider, pays no attention whether he be on his back or not, walks straight on when

once set agoing, merely because he is too stupid to turn aside, and then should some tempting thorn or green branch allure him out of the path, continues to walk on in the new direction simply because he is too dull to turn back into the right road. In a word, he is from first to last an undomesticated and savage animal rendered serviceable by stupidity alone, without much skill on his master's part, or any co-operation on his own, save that of an extreme passiveness. Neither attachment nor even habit impress him; never tame, though not wide-awake enough to be exactly wild." So also Sir S. Baker, in his recent work *The Albert Nyanza*, bears testimony to its extreme dulness, for while other ruminants in feeding select wholesome herbs, the camel is stupid enough to eat indiscriminately every green vegetable; it is thus often poisoned through eating a plant known to the Arabs as "camel poison," and on this account it is customary to set watchers over them while grazing in districts where this plant is found. The camel, however, is revengeful, and in satisfying this passion is said to display a far-thoughted malice scarcely consistent with the extreme stupidity attributed to it by Palgrave. Of this vindictiveness the camel driver is well aware, and of the certainty that sooner or later it will seek revenge; accordingly it is customary for the person who has reason to fear its malice to throw his clothes before the camel, meanwhile concealing himself until the infuriated animal has expended its rage in tossing and trampling upon them, when the injury, real or supposed, is immediately forgotten.

The camel is probably a native of the desert countries of the south-west of Asia, whence it has spread into most of the arid regions of the eastern hemisphere, carrying with it wherever it goes a mark of its desert origin in the antipathy which it shows to cross a stream of water. It has lately been introduced into Australia, the great central desert of which was recently crossed by Warburton with a caravan of camels. It has now also obtained a footing in the New World, ten camels having been landed at New York some years ago, all of them, however, with the exception of a single male and female, dying soon after. The surviving pair were transferred to Nevada, where the soil was sandy and sterile, producing abundance of prickly shrubs which no other animal would touch, but on which the pair of camels flourished and bred. This female has already given birth to twenty-four young, all of which are still (1875) alive, and some of these having also bred, there are now ninety-six camels, all, with the exception of the original couple, born in Nevada. In Europe the camel is only reared in the neighbourhood of Pisa, having been introduced there by one of the dukes of Tuscany, and is employed as a beast of burden, but is said to be gradually deteriorating.

There are two species of camel—the Arabian and the Bactrian. The former or single-humped species (*Camelus dromedarius*) is found in greatest perfection in Arabia, whence it has spread eastwards to India, where it is now extensively used, although the stony nature of much of the ground it has to pass over does not give it in India that superiority over other beasts of burden, which it undoubtedly possesses in desert countries. It seems to have spread westwards with the Koran along the North African shores, and to have been introduced by the Moors into Spain, where, however, it did not succeed in establishing itself. It also accompanied the followers of Mahomet into European Turkey. In Arabia several breeds, each possessing special qualities, are carefully cultivated. The chief of these are the thick-built, heavy-footed, and slow-paced variety, used for carrying heavy loads, and the dromedary—a name often applied to all the members of the single-humped species, but properly belonging *only* to a thin, comparatively elegant, and fine-haired breed, celebrated for its fleetness, carrying its rider when necessary 100 miles a day. The dromedary, says Palgrave, "is the race-horse of its species," and the difference between it and the heavy variety is exactly the same "as between the race-horse and a hack." Another breed, belonging to a tribe of Arabs who dwell near the western shores of the Red Sea, is specially adapted for journeying with loads over mountainous districts, and Baker, who made use of them, states that they accomplished feats in mountain climbing which would have been impossible to any other domestic animal so loaded. The Bactrian or two-humped camel (*Camelus bactrianus*) is a somewhat larger and more robust species, and is much rarer than the Arabian. It is found throughout the region lying to the north and east of that inhabited by the dromedary, from the Black Sea to China and northward to Lake Baikal, where in winter it sustains severe cold, subsisting meanwhile upon the leaves and twigs of the willow and birch. The pads on its feet are harder than in the other species, and are thus better fitted to bear the changes wrought on the soil by the frequent alternations of rain and drought, while its fur is also thicker and more plentiful. In Central Asia both species occur, and hybrids are not uncommon, the latter being, it is alleged, occasionally fertile among themselves. (J. GI.)

CAMELLIA, the name of a genus of *Ternströmiaceæ*, remarkable for its evergreen laurel-like foliage, and its handsome rose-like flowers, whence the common species, *C. japonica*, is sometimes called the Japan rose. This is an evergreen shrub of remarkably hardy constitution, so that in our climate it flourishes perfectly in a cold greenhouse; indeed, in the south and west of England, and in other favourable situations, the plant itself is hardy, and only suffers from frost in regard to the damage done to its flowers, which are naturally developed very early in the spring, and are therefore liable to suffer injury from spring frosts. The plant had been cultivated by the Japanese and Chinese long previous to its introduction to our gardens from China in 1739, and, in consequence, numerous double-flowered varieties were at that time known, of which about two dozen sorts were introduced from China, chiefly between 1806 and 1824, some two or three others having been obtained so early as 1792–4. This number of varieties has now been very considerably increased by the production of European seedlings, so that several hundreds are figured in a publication called *Nouvelle Iconographie des Camellias*, specially devoted to their illustration. The plant seeds freely in the climate of Italy and the south of Europe, and thence many first-rate sorts have been obtained.

The original type of *C. japonica* forms a dense bushy evergreen, abundantly clothed with ovate acuminate glossy leaves, and decorated with sessile single red flowers composed of from five to seven (nominally five) broadly obovate rosy carmine petals, which expand into a cup-shaped flower, and surround a circlet of numerous monadelphous stamens, within which a few free stamens, two to each petal, are produced. These stamens afford a fine contrast to the broad spreading petals. This form, or one but slightly removed from it, is still cultivated in gardens, as a stock on which to graft the double-flowered sorts, these only, in a general way, being now prized. There are, however, some few exceptions, as, for example, the single white, whose large flowers, with their conspicuous stamens, are extremely handsome when associated with the rich-looking dark green foliage.

The name *Camellia* was given to these plants by Linnæus in honour of George Joseph Camellus or Kamel, a Moravian Jesuit, who travelled in Asia, and wrote a history of the plants of the island of Luzon. In Japan, its native country, the *Camellia* attains to the size of a large tree, and it is held in high estimation by the Japanese on account of the extreme beauty of its large, showy, and

various-coloured flowers, which, however, have this drawback, that they have no scent. It appears to have been cultivated by the Chinese from time immemorial, and all our earlier introductions were obtained from that country. According to the *Hortus Kewensis*, it was introduced into England by Robert James, Lord Petre, before the year 1739; and the Waratah, or anemone-flowered variety, which has broad outer petals and a crowd of smaller central ones, is said to have been introduced at the same time. The double white, a variety as yet unsurpassed in beauty, its flowers being so pure in colour, and so full and symmetrically imbricated in form, was introduced in 1792; as also was the double striped, a free blooming hardy kind, with rosy red flowers irregularly blotched with white, which though surpassed in size and richness of colouring by more modern European varieties, is still too useful to be altogether discarded. The latest direct importations are probably the hexangular-flowered Camellia (*hexangularis*), introduced from China by Mr Fortune in 1846, a variety which, like that called Lady Hume's Blush (*incarnata*), has the pointed petals laid directly over each other, so that the face of the flower becomes six-angled; and the fish-tailed Camellia, introduced in 1861, a variety in which the leaves are sharply serrated at the margin and forked at the apex, so that they resemble in form the tail of a fish.

To be seen in their full perfection Camellias should be planted out in borders of properly prepared soil under glass; but these borders should be very effectually drained, and of such a mechanical composition as never to become soddened, for the plants require to be almost deluged with water when making their growth, and when developing their blossoms. The borders, moreover, when the plants have become well established, and the soil is full of roots, will require to be assisted by top-dressings, such as sheep or deer dung, and by applications of liquid manure. They by no means require a heated structure, nor too much sunlight, but when well established in a cool and somewhat shaded conservatory, may become a source of infinite delight to those who have a love for flowers. As instances of the great esteem in which the *Camellia* is held, it is only necessary to refer to the immense number of cut blooms sold during the season in Covent Garden market, and the high prices which they realize while yet comparatively scarce.

The genus *Camellia* is limited to some six or seven species, natives of India and Japan. Of these, besides *C. japonica*, another named *C. reticulata*, a native of the island of Hong-Kong, is highly prized in gardens for its very handsome blossoms. It differs from *C. japonica* in its downy branches, and reticulated, not glossy leaves, and also in its much larger flowers. The double-flowered variety of this plant has a most gorgeous appearance, specimens of the flowers having been measured which were as much as twenty inches in circumference.

Both *C. Sasanqua* (=*oleifera*), and *C. drupifera* (=*Kissii*), the former inhabiting Japan and China, the latter Cochin-China and the mountains of India, are oil-yielding plants. The oil of *C. Sasanqua* (of which Sasankwa is the native Japanese name) has an agreeable odour, and is used for many domestic purposes; it is obtained from the seeds by subjecting them to pressure sufficient to reduce them to a coarse powder, and then boiling and again pressing the crushed material. The leaves are also used in the form of a decoction by the Japanese women, for washing their hair; and in a dried state they are mixed with tea on account of their pleasant flavour. The oil of *C. drupifera*, which is closely allied to *C. Sasanqua*, is used medicinally in Cochin-China, its flowers also are odoriferous, all the other known species, except the Indian *C. lutescens*, being inodorous.

The genus *Camellia* is very closely allied to that of the tea-plant (*Thea*); indeed so close is the affinity that some botanists have proposed to unite them. Dr Seemann, however, in a memoir published in the *Transactions of the Linnean Society* (xxii. 337), points out their distinctions, from which it appears that while in *Camellia* the flowers are erect and sessile, the calyx many-leaved with deciduous sepals, the interior stamens (those within the monadelphous ring) twice the number of petals, and the styles five in number, the flowers of *Thea* are pedunculate and nodding, the calyx five-sepaled with persistent sepals, the interior stamens equalling the petals in number, and the styles three. So close, however, is the agreement between them that the red-flowered *Camellia Sasanqua*, as it was for a long time called in gardens, has, as a result of more intimate acquaintance with its structure, to be referred to *Thea*, under the name of *Thea maliflora*. Bentham and Hooker, in their new *Genera Plantarum*, have again united *Thea* with *Camellia* under the latter name, preferring to regard the teas as forming a section of the genus *Camellia*, which conclusion has been adopted by Professor Dyer in the *Flora of British India* (i. 292), where the *Thea assamica* of authors is referred to as the possible wild stock of the tea-plant, and the name of *Camellia theifera* adopted for the combined form called *T. chinensis* by Linnæus and Seemann. (T. MO.)

CAMEO, a term of doubtful origin, applied to engraved work executed in relief, on hard or precious stones, on imitations of such stones in glass called "pastes," or on the shells of molluscous animals. A cameo is thus the converse of an intaglio, which consists of an incised or sunk engraving executed in the same class of materials. The word cameo is generally regarded as being derived from the Arabic *camea*, a charm or amulet; but a number of other derivations have been suggested, among which a highly allegorical origin of the word from the Arabic *camaut*, the camel's hump, implying any object in relief, has been maintained by an eminent authority. Cameo-cutting is an art of much more recent introduction than the sister art of intaglio-engraving. The earliest known traces of any attempt at cutting gem-figures in relief are seen in certain Phœnician and Etruscan scarabei, in which the back of the beetle has been utilized for the faint delineation of another and quite different figure. One of the most ancient known cameos, of which the date can be fixed with certainty, consists of a sardonyx of three layers with portrait heads of Demetrius Soter and his wife Laodice, which must have been engraved between the years 162 and 150 B.C.

The materials which ancient artists used for cutting into cameos were chiefly those siliceous minerals which, under a variety of names, present various strata or bands of two or more distinct colours, and properly the name cameo should be restricted to work executed in relief on such banded stones. The minerals, under different names, are essentially the chalcedonic variety of quartz, and the differences of colour they present are due to the presence of variable proportions of iron and other foreign ingredients. These banded stones, when cut parallel to the layers of different colours, and when only two coloured bands—white and black, or sometimes white and black and brown—are present, are known as onyxes, but when they have with the onyx bands layers of carnelian or sard, they are termed sardonyxes. The sardonyx, which was the favourite stone of ancient cameo-engravers, and the material in which their masterpieces were cut, was procured from India, and the increased intercourse with the East by the way of Egypt after the death of Alexander the Great had a marked influence on the development of the art. Cameo-cutting in Rome attained the zenith of its pristine perfection during the first two centuries of the Christian era, the chief works being portraits of the reigning families, and allegorical illustrations of their glories. Contemporaneously with the production of the finest works in Oriental precious stones, pastes or imitations in glass were made in incredible numbers to meet the requirements of the classes who could not afford the other necessarily rare and costly luxuries. Both in perfection of material and in artistic merit these imitations were, in the best period, of extraordinary merit. The Barberini or Portland vase in the British Museum is a rare example of the skill of both the glass-worker and engraver on glass of ancient times.

The two most famous examples of this art which have come down to the present day are the Great Agate of the Sainte Chapelle in the Bibliothèque Nationale, Paris, and the Augustus Cameo in the Vienna collection. The former

was pledged among other valuables in 1244 by Baldwin II. of Constantinople to Saint Louis. It is mentioned in 1344 as "Le Camahieu," having been sent in that year to Rome for the inspection of Pope Clement VI. It is a sardonyx of five layers of irregular shape, like all classical gems, measuring about 13 inches by 11 inches. During the Middle Ages the subject was supposed to be the triumph of Joseph in Egypt; but it is now known to represent on its upper part the apotheosis of Augustus, the centre being occupied with the reception of Germanicus on his return from his great German campaign by the Emperor Tiberius and his mother Livia. The lower division is filled with a group of captives in attitudes expressive of woe and deep dejection. The Vienna gem (*Gemma augustea*), an onyx of two layers measuring 9 inches by 8, is a work of still greater artistic interest The upper portion is occupied with an allegorical representation of the coronation of Augustus,—the emperor being represented as Jupiter with Livia as the goddess Roma at his side. In the composition Neptune and Cybele, with several members of the family of Augustus, are introduced, and on the exergue or lower portion are Roman soldiers preparing a trophy, barbarian captives, and female figures. The history of this inestimable treasure has been traced from the time of the Crusades, and it came into the possession of the Emperor Rudolph II. in the 16th century for the enormous sum of 12,000 gold ducats

While these and other similar monuments of antiquity, which have come down to us only mellowed and not injured by time, have intrinsically a priceless value as the expression of the most perfect artistic culture and feeling of the age to which they belong, they possess at the same time equally great significance to the student of the history, civilization, morals, and manners of the period. They supply the most authentic means of confirming the inferences to be drawn from classical sources as to beliefs, usages, dress, domestic and public habits, and pursuits of the people with whom they deal, and by means of such gems not only are the prevailing features of an ancient race accurately delineated, but the actual portraits of many of the most prominent personages in the world's history have been faithfully preserved, and can be identified beyond the shadow of a doubt.

The art of cameo-engraving waned in the early part of the 3d century, after the death of the Emperor Severus, but under the first Christian Emperor Constantine it enjoyed a brief period of revival. Many very beautiful cameo portraits of Constantine are extant; and it was during or shortly after his reign that Christian Scripture subjects began to appear on cameos. That class of subjects constituted the staple of such work—generally rude and artistically debased—as continued to be cultivated under the Byzantine empire down to nearly the epoch of the Renaissance. From the Byzantine period downward one peculiarity of gem-engraving becomes noticeable. Cameo-work as compared with intaglios in classical times was rare and infrequent, but now and onwards the opposite is the case, intaglio-sinking having almost died out, and cameos being chiefly produced. Commercial intercourse with the East still secured for the engravers a supply of magnificent sardonyxes, although blood-stone and other non-banded stones were very commonly used for works in relief. Cameos during the long dark ages were used chiefly for the decoration of reliquaries and other altar furniture, and as such their designs were purely ecclesiastical or scriptural. To this period also belongs the class of complimentary or motto cameos, which, containing only inscriptions and an ornamental border, executed in nicolo stones, were used as personal gifts and adornments.

In mediæval times antique cameos were held in peculiar veneration on account of the belief, then universal, in their potency as medicinal charms. This power was supposed to be derived from their origin, of which two theories, equally satisfactory, were current. By the one they were held to be the work of the children of Israel during their sojourn in the wilderness (hence the name *Pierres d'Israel*), while the other theory held them to be direct products of nature, the engraved figures pointing to the peculiar virtue lodged in them.

The revival of the glyptic arts in Western Europe dates from the pontificate of the Venetian Paul II. (1464–71), himself an ardent lover and collector of gems, to which passion, indeed, it is gravely affirmed he was a martyr, having died of a cold caught by the multiplicity of gems exposed on his fingers. The cameos of the early part of the 16th century rival in beauty of execution the finest classical works, and, indeed, many of them pass in the cabinets of collectors for genuine antiques, which they closely imitated. The Oriental sardonyx was not available for the purposes of the Renaissance artists, who were consequently obliged to content themselves with the colder German agate onyx. The scarcity of worthy materials led them to use the backs of ancient cameos, or to improve on classical works of inferior value executed on good material, and probably to this cause must also be assigned the introduction of shell cameos, which are not supposed to have been made previous to this period.

Among the means of distinguishing antique cameos from cinquecento work, the kind of stone is one of the best tests, the classical artists having used only rich and warm-tinted Oriental stones, which further are frequently drilled through their diameter with a minute hole, from having been used by their original Oriental possessors in the form of beads. The cinquecento artists also, as a rule, worked their subjects in high relief, and resorted to undercutting, no case of which is found in the flat low work of classical times. The projecting portions of antique work exhibit a dull chalky appearance, which, however, fabricators learned to imitate in various ways, one of which was by cramming the gizzards of turkey fowls with the gems. Another index of antiquity is found in the different methods of working adopted in classical and Renaissance times. The tools employed by the Renaissance engraver were the drill and the wheel, both fed with oil and diamond or emery dust. The drill was simply the common instrument known by that name, and the wheel was a small metallic disc, which cut by its periphery being made to rotate in a vertical plane. Antique gems of the best period were cut or scratched (γλύφειν, *scalpere*) with the diamond point (splinters either of corundum or sapphire), with the aid of the drill, which the artists possessed in common with their modern successors.

In the early part of the 18th century great confusion was introduced into the study of this department of art, by the fraudulent insertion on a wholesale scale of names in Greek, purporting to be those of the engravers of the gems bearing them. In reality the insertion of his name by any artist, on cameos especially, was an exceedingly rare occurrence. An invariable and unfailing test of the authenticity of any signature on a cameo is "that it be always in relief, which is a sure evidence that it was cut at the same time with the rest of the composition." Another fraud practised in Italy during the revival consisted in engraving on unnamed portrait gems a name supposed to suit the aspect of the individual.

In our own day the engraving of cameos has ceased to be pursued as an art. Roman manufacturers cut stones in large quantities to be used as shirt-studs and for setting in finger-rings; and in Rome and Paris an extensive trade is carried on in the cutting of shell cameos, which are

largely imported into England and mounted as brooches by Birmingham jewellery manufacturers. The principal shell used is the large bull's-mouth shell (*Cassis rufa*), found in East Indian seas, which has a sard-like underlayer. The black helmet (*Cassis tuberosa*) of the West Indian seas, the horned helmet (*C cornuta*) of Madagascar, and the pinky queen's conch (*Strombus gigas*) of the West Indies are also employed. The famous potter Josiah Wedgwood introduced a method of making imitations of cameos in pottery by producing white figures on a coloured ground, this constituting the peculiarity of what is now known as Wedgwood ware. (J. PA.)

CAMERA LUCIDA, an instrument invented by Dr Wollaston for drawing in perspective.

If a piece of plane glass be fixed at an angle of 45° with the horizon, and if, at some distance beneath, a sheet of paper be laid horizontally on a table, a person looking downwards through the glass will see an image of the objects situated before him; and as the glass which reflects the image is also transparent, the paper and pencil can be seen at the same time with the image, so that the outline of the image may be traced on the paper. The image is an *inverted* one. This is the simplest form of the instrument, and may be constructed extemporaneously by fixing on a stand a plane transparent glass, with its surfaces ground parallel, or a piece of Muscovy glass, at an angle of 45° with the horizon. A card with a small hole in it will serve as a sight for keeping the eye steady in one situation whilst the pencil is tracing the image.

Let a plane mirror, *cb* (Plate XXXIV. fig. 1), be inclined at an angle of 22½° with the horizon, and let *ba*, a piece of plane transparent glass, be so placed as to make an angle of 22½° with the vertical, then rays *fg* from an object will be twice reflected before they reach the eye at *e*, and, consequently, on looking down through the transparent glass, an *erect* image is seen, and the pencil may be drawn over the outlines of this image, so as to leave a perspective representation on the paper.

As the image and pencil are at different distances, they cannot be both seen in the same state of the eye. To remedy this inconvenience, a convex glass is used, of such focus as to require no more effort than is necessary for seeing the distant objects distinctly. By means of this lens, the image will appear as if it were placed on the surface of the paper. In fig. 1, *bd* is a convex glass of 12 inches focus. Instead of using a convex lens, short-sighted persons will require a concave glass to be placed at *f*, in the course of the rays from the object to the reflecting surface. In fig. 2, *ik* is a concave glass so placed that it may be turned at pleasure into its place, as the sight of the observer may require. Persons whose sight is nearly perfect may use either the concave glass placed before the reflecting surface, or the convex placed between the paper and the eye.

In the actual construction of the instrument, a prism is used instead of a mirror and plane glass. The rays from the object fall upon the surface *bc* of the prism, fig. 3. This surface *bc* is inclined 22½° to the horizon. The refractive power of the glass allows none of the rays in this situation to pass out; they are all reflected from the surface *bc* to the surface *ab*, and from that to the eye. *ab* makes an angle of 135° with *bc*, and 22½° with the vertical. The eye cannot see the pencil through the prism as it does through a plane glass; therefore, in order that the pencil may be seen, the eye must be so placed that only a part of the pupil may be above the edge of the prism, as at *e*, fig. 3; and then the reflected image will be seen at the same time with the paper and pencil. There is a small piece of brass perforated with a hole *c* (fig. 2), and moving on a centre; this serves to keep the eye in one position, as it must be that the image may be steady, and also to regulate the relative quantities of light to be received from the object and from the paper.

The instrument, being near the eye, does not require to be large. The smallest size which can be executed with accuracy is to be preferred, and is such that the lens is only three-fourths of an inch in diameter. Fig. 4 shows the instrument on its stand, and clamped to a board. The joint by which the prism is attached to the stand is double.

This instrument serves for drawing objects of all forms, and consequently also for copying lines already drawn on a plane surface. If it is required that the copy shall be of the same size as the original drawing, the distance of the drawing from the prism should be the same as the distance of the paper from the eye-hole. No lens will be necessary in this case, because the image and the paper, being both at the same distance from the eye, coincide without the aid of a glass.

In order to have a reduced copy of a drawing, the drawing is to be placed at a distance from the prism greater than the distance of the paper from the eye-hole. If the distance is twice as great, a copy will be obtained in which the lines are of one-half the size of the lines in the original, and so in proportion for other distances. A lens is necessary, that the eye may be enabled to see at two different distances; and, in order that one lens may serve, the distance between the eye-hole and the paper should be variable; to that effect the stand is susceptible of being lengthened or shortened at pleasure.

The length of the stem is adjusted upon optical principles. When a distant object is to be delineated, the rays coming from it, and reflected by the instrument to the eye, are parallel, and it is required that the rays proceeding from the paper to the eye should also be parallel. This is accomplished by interposing a lens between the paper and the eye, with its principal focus on the paper. When the object to be delineated is so near that the rays which come from it to the eye are divergent, then it is required that the rays from the paper should likewise be divergent in the same degree, in order that the paper and the image may both be seen distinctly by the same eye; for this purpose the lens must be placed at a distance from the paper less than the distance of its principal focus.

The advantage of this instrument as compared with the camera obscura are,—1*st*, That it is small and easily carried about; 2*dly*, That no lines are distorted, not even those most remote from the centre; and 3*dly*, That in the field of the camera lucida 70° or 80° may be included, whilst the distinct field of the camera obscura does not extend beyond 30° or 35° at most. See *Repertory of Arts*, vol. x., 1807, p. 162, and Nicholson's *Journal*, vol. xvii.

If the camera lucida be fixed at the eye-glass of a telescope, it will reflect to the eye the image of the objects in the field of the telescope, so that a drawing of the image may be made. See Brewster's *Account of some Philosophical Instruments*. A plane reflecting glass fixed at an angle of 45° with the horizon, and placed so as to receive the rays from the eye-glass of a telescope, will also give an image of the objects in the field, so situated that the image may be traced with a pencil. Varley's patent graphic telescope is upon this principle. In order that the field may be large, the magnifying power of the telescope should be small.

The optigraph of Ramsden and Thomas Jones, described in the *Philosophical Magazine*, vol. xxviii., 1807, p. 67, is an instrument of a similar kind. The image of the object is seen in a telescope. There is a piece of plane glass near *c*, in the focus of the eye-glass of the telescope F, Plate XXXIV. fig. 5. On the centre of this piece of glass is a dot; *a* is a plane mirror, inclined so as to reflect the image of the object into the telescope. This mirror remains fixed, whilst

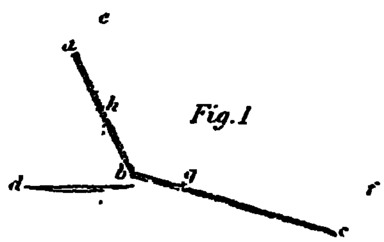

Fig.1

Fig.3. Prism of Camera

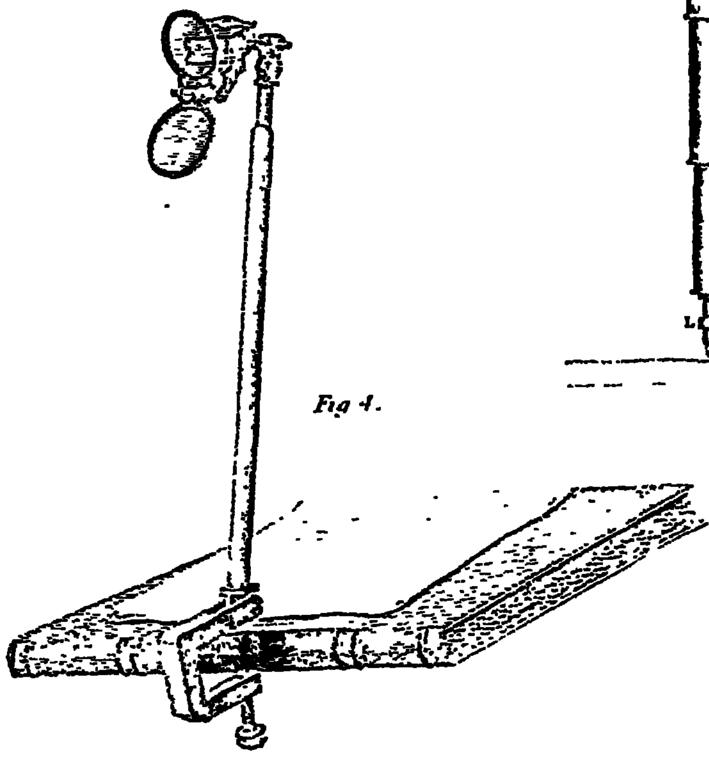

Fig 4.

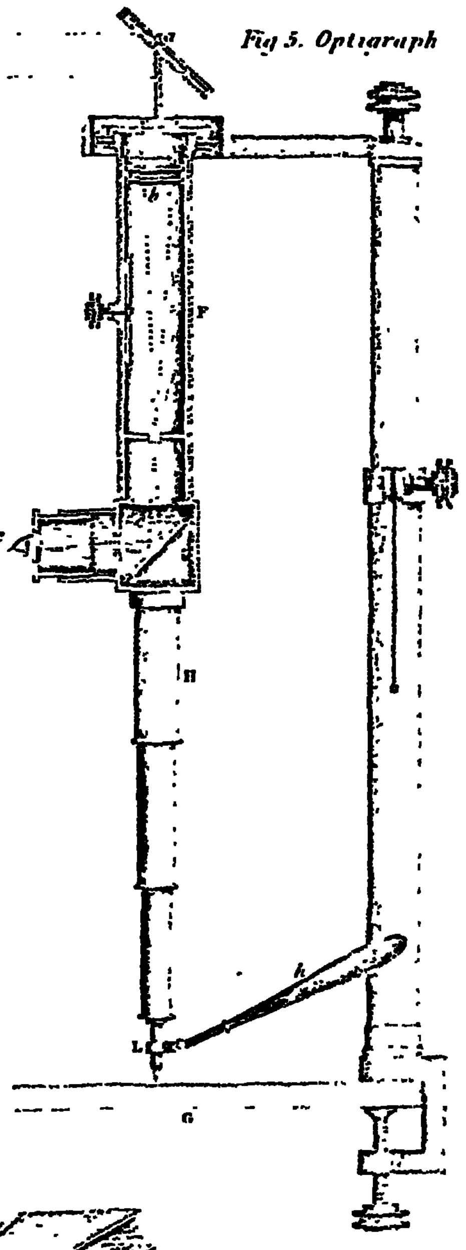

Fig 5. Optigraph

the telescope is movable on a universal joint at its object-glass *b*. Near *c* is another plane mirror, which reflects the rays to the eye-glass. The eye being placed at the eye-glass at *e*, the telescope is to be moved by the handle *h* so that the dot in the focus of the eye-glass shall pass over the outlines of the image seen by the eye, and the pencil at L performing a similar motion to that of the dot, and sliding freely in its sheath, presses with its weight on the paper; a drawing of the object is the result. If the stand and slider H be lengthened, an enlarged drawing will be obtained.

CAMERA OBSCURA, an optical apparatus, consisting of a darkened chamber, at the top of which is placed a box or lantern, containing a convex lens and sloping mirror, or a prism combining the lens and mirror. The rays of light from surrounding objects are received by the lens, and the mirror reflects images of the scenery downwards on a table placed underneath. This ingenious contrivance is said to have been invented by Baptista Porta in the end of the 16th century. For the camera obscura used by photographers see PHOTOGRAPHY.

CAMERARIUS, JOACHIM (1500-1574), whose family name was Liebhard, one of the most learned classical scholars of his time, was born at Bamberg on the 12th April 1500. He studied at Leipsic, Erfurt, and Wittenberg, and in the last-mentioned town he enjoyed the friendship of Melanchthon. For some years he was teacher of history and Greek at the Gymnasium, Nuremberg. In 1530 he was sent as deputy for Nuremberg to the Diet of Augsburg, where he rendered important assistance to Melanchthon. Five years later he was commissioned by Duke Ulrich of Würtemberg to reorganize the university of Tübingen; and he subsequently rendered a similar service at Leipsic, where the remainder of his life was chiefly spent. He translated into Latin Herodotus, Demosthenes, Xenophon, Homer, Theocritus, Sophocles, Lucian, Theodoret, Nicephorus, and other Greek writers. He published upwards of 150 works, including a *Catalogue of the Bishops of the principal Sees*; *Greek Epistles*; *Accounts of his Journeys*, in Latin verse; a Commentary on Plautus; *Euclid*, in Latin; and the Lives of Helius Eobanus Hessus and Philip Melanchthon. He died at Leipsic in 1574.

CAMERARIUS, JOACHIM (1534-1598), a learned physician, son of the preceding, was born at Nuremberg, 6th November 1534. After having finished his studies in Germany he visited Italy, where he graduated as doctor of medicine. On his return he was invited to reside at the courts of several princes; but he was too much devoted to the study of chemistry and botany to accept their offers. He settled in his native town of Nuremberg, where he practised as a physician, and was the chief agent in founding a medical school. He wrote a *Hortus Medicus*, and several other works. He died on the 11th October 1598.

CAMERINO, formerly the capital of a delegation of the same name in the States of the Church, and now the chief town of a district, in the province of Macerata, in Italy, is situated on a height at the foot of the Apennines, 41 miles W. of Ancona. It is the seat of an archbishop, and possesses a small university founded in 1727, a theological seminary, nineteen conventual buildings, and a bronze statue of Pope Sixtus V., dating from 1587. Its cathedral, Sansovino, is built on the site of an ancient temple to Jupiter, and contains a number of excellent paintings. The culture and manufacture of silk is by far the most important branch of industry; to which may be added the preparation of leather. Camerino occupies the site of the ancient *Camerinum*, an Umbrian city, whose inhabitants, the *Camertes*, are mentioned as an important people at a very early date. About the beginning of the Christian era its lands were bestowed on military colonists; but it continued to enjoy considerable prosperity. In the Middle Ages it originally formed part of the duchy of Spoleto; but it passed in the 13th century to the Varani family, and in 1520 was made an independent duchy by Leo X. About seventy years afterwards it was incorporated by the Papal States. The painter Carlo Maratta, the last of the so-called Roman school, was a native of the city. Population, 11,880.

CAMERON, JOHN (1579-1623), a learned theologian, was born at Glasgow about 1579, and received his early education in his native city. After having taught Greek in the university for twelve months, he removed to Bordeaux, where he was soon appointed a regent in the College of Bergerac. He did not remain long at Bordeaux, but accepted the offer of a chair of philosophy at Sedan, where he passed two years. He then returned to Bordeaux, and in the beginning of 1604 he was nominated one of the students of divinity who were maintained at the expense of the church, and who for the period of four years were at liberty to prosecute their studies in any Protestant seminary. During this period he acted as tutor to the two sons of Calignon, chancellor of Navarre. They spent one year at Paris, and two at Geneva, whence they removed to Heidelberg, where they remained nearly twelve months. In this university, on the 4th of April 1608, he gave a public proof of his ability by maintaining a series of theses, *De triplici Dei cum Homine Fœdere*, which were printed among his works. The same year he was recalled to Bordeaux, where he was appointed the colleague of Dr Primrose; and when Gomarus was removed to Leyden, Cameron, in 1618, was appointed professor of divinity at Saumur, the principal seminary of the French Protestants.

In 1620 the progress of the civil troubles in France obliged Cameron to seek refuge for himself and family in England. For a short time he read private lectures on divinity in London; and in 1622 the king appointed him principal of the university of Glasgow in the room of Robert Boyd, who had been removed from his office in consequence of his adherence to Presbyterianism. His successor appears to have been more favourably inclined to Episcopacy,—a circumstance that may have tended to diminish the cordiality of his reception in his native city. Here he also taught divinity with great reputation, but he resigned his office in less than a year. Calderwood says that "Cameron was so misliked by the people that he was forced to quit his place soon afterwards."

He returned to France, and fixed his residence at Saumur; and after an interval of a year he was appointed professor of divinity at Montauban. The country was still torn by civil and religious dissensions; and as Cameron maintained the doctrine of passive obedience, he excited the indignation of the more strenuous adherents of his own party. He withdrew to the neighbouring town of Moissac; but he soon returned to Montauban, and a few days afterwards he died at the age of about forty-six. Cameron left by his first wife several children, whose maintenance was undertaken by the Protestant churches in France. All his works were published after his death.

His name has furnished a designation to a party of Calvinists in France, who asserted that the will of man is only determined by the practical judgment of the mind; that the cause of men's doing good or evil proceeds from the knowledge which God infuses into them; and that God does not move the will physically, but only morally, by virtue of its dependence on the judgment of the mind. This peculiar doctrine of grace and free-will was adopted by Amyraut, Cappel, Bochart, Daillé, and others of the more learned among the Reformed ministers, who judged Calvin's doctrines on these points too harsh. The Cameronites are moderate Calvinists, and approach to the opinion of the Arminians. They are also called

Universalists, as holding the universal reference of Christ's death, and sometimes Amyraldists. The rigid adherents to the Synod of Dort accused them of Pelagianism, and even of Manicheism, and the controversy between the parties was carried on with great zeal; yet the whole question between them was only, whether the will of man is determined by the immediate action of God upon it, or by the intervention of a knowledge which God impresses on the mind. The Synod of Dort had laid down the position that God not only illuminates the understanding, but gives motion to the will by making an internal change therein; whereas Cameron admitted only the illumination by which the mind is morally moved, and attempted to explain the decision of the Synod of Dort so as to make the two opinions consistent.

CAMERON, Richard (? –1680), the founder of the Cameronians, was born at Falkland, in the county of Fife. The date of his birth is not known. His father, who was a shopkeeper in that town, gave him such an education as the village school afforded; and his success was so great that, while still a youth he was appointed schoolmaster. In this situation he had opportunities of becoming acquainted with some of the more enthusiastic field-preachers, who at this time wandered through the country disseminating their doctrines. Persuaded by them he resigned his situation, and shortly after entered the family of Sir Walter Scott of Harden as chaplain and tutor. He did not remain there long, however, for, refusing to acknowledge the Indulgence, he joined the ranks of the nonconforming ministers, and incited the inhabitants of the southern counties of Scotland to protest openly against the new edict. So formidable was the agitation that the Government thought fit to interfere, and pronounced illegal all armed assemblages for religious purposes. Cameron was obliged to take refuge in Holland, where he resided for some time; but in the spring of 1680 he returned to Scotland, and once more made himself formidable and obnoxious to the Government. Shortly after the defeat of the Covenanters at Bothwell Bridge in that year, Cameron was slain in a skirmish at the Aird's Moss, fighting bravely at the head of the few troops which he had been able to collect, and which formed the nucleus of the renowned regiment in the British army afterwards known by his name.

CAMEROONS, or perhaps preferably Camaroons, is the greatest mountain-mass on the western coast of Africa. It is situated at the angle of the Bight of Biafra, directly opposite the island of Fernando Po, with which it has evidently an intimate geological connection. Its European name is said to be derived from the Portuguese Camarões (shrimps or prawns), and to have been bestowed by the early discoverers on the neighbouring coast from the abundance of its crustacea. The native designation of the highest peak is Mongo-má-Lobá, or the Mountain of the Sky, and the whole upper region is usually called Mongo-mo-Ndemi, or the Mountain of Greatness. The area of the Cameroons proper is calculated at about 380 square miles; but offshoots and underfalls seem to stretch both north and south for considerable distances. The pile is of distinctly volcanic formation, and the higher district contains numerous craters and lava-beds of comparatively recent date. On the principal summit, whose twin peaks of Mount Albert and Victoria rise to a height of about 13,120 feet above the sea-level, there are one small and two large craters, from which, if native report can be trusted, eruptions have taken place within the memory of man (1838). The lower portions of the mass are occupied by a luxuriant vegetation of palms, acacias, fig-trees, kokos, plantains, and a rich variety of tree and shrub; while at the height of about 7000 feet these give place to ferns, grasses, and heaths. The climate of the middle zone would render it an excellent site for a sanatorium for Europeans debilitated by the malaria of the neighbouring coasts; and the fertility of the soil would soon raise the district to great commercial importance, if it were brought under cultivation. The native tribes which inhabit the mountain sides are comparatively few, and have a very small proportion of the surface in actual possession. To the south of the Cameroons lies the Bay of Ambas (Ambozes, or Amboize), with the two islands of Ndami and Mondori. It forms a well-sheltered harbour, and is capable of receiving the largest vessels. In 1837 the king of Bimbia on the mainland made over a large part of the country round the bay to Colonel Nicolls, and in 1848 he agreed to abolish human sacrifices at the funerals of his great men. In 1858 a settlement was made on the coast at the mouth of a small river, flowing into Morton Cove, now known as the Victoria River. The settlers were Mr Saker, a Baptist missionary, and his converts, who removed from Fernando Po, when the Spanish authorities published an edict forbidding public worship to be celebrated by any but the Roman Catholic clergy. To the south-east of the mountains flows the Cameroons River, where the Baptist mission has had a station since 1850. The most important tribe is the Duallas, whose language has been reduced to writing within recent years. The ascent of the Cameroons Mountains was first attempted by Mr Merrick in 1847; but it was not till 1861 that the summit was actually gained by Captain Richard Burton and Mr Mann, a botanist. See Burton's *Abeokuta and the Cameroons Mountains*, 1863; papers by Mr Mann in the *Proceedings of the Linnæan Society*; also *Zeitschrift d. Gesellschaft für Erdk. zu Berlin*, 1874, and Petermann's *Mittheil.*, 1863.

CAMILLUS and CAMILLA, in Roman Antiquity, the title applied to the boys and girls who were occupied in the ceremonies of sacrifice, whether temporarily or as a preparation for their entering the priesthood. In the latter case it was necessary that they should be the children of parents still alive (*patrimi et matrimi*) and freeborn. The name Camillus has been identified with the Cadmilus or Casmilus of the Samothracian mysteries.

CAMILLUS, Marcus Furius, one of the most illustrious heroes of the Roman republic. He triumphed four times, was five times dictator, and was honoured with the appellation of Second Founder of Rome. When accused of having unfairly distributed the spoil taken at Veii, he anticipated judgment, and went voluntarily into exile at Ardea. But during his exile, instead of rejoicing at the devastation of Rome by the Gauls, he exerted himself to repel the enemy, and yet kept with the utmost strictness the sacred law of Rome, in refusing to accept the command, which was offered him by several private persons. The Romans, when besieged in the Capitol by the Gauls, created him dictator; and in this capacity he acted with so much bravery and conduct, that he entirely drove the enemy out of the territories of the commonwealth. He died of the plague in the eighty-first year of his age, 365 B.C. The famous story of Camillus and the schoolmaster belongs to the campaign against the Faliscans in 394. It is said that when Camillus appeared before Falerii, a schoolmaster attempted to betray the town by bringing into his camp the sons of some of the principal inhabitants of the place. Camillus, indignant at such baseness, ordered that the traitor should have his hands tied behind him, and be whipped into the town by his own scholars. It is said that the Faliscans were so affected by the generosity of the Roman general that they immediately surrendered (Livy; Plutarch). For a critical estimate of the remnant of historic truth that lies under the somewhat amplified legendary history of Camillus see Roman History.

CAMISARDS was the name given to the peasantry of the Cévennes who, from 1702 to 1705 and for some years afterwards, carried on an organized military resistance to the *dragonnades*, or conversion by torture, death, and confiscation of property, by which, in the Huguenot districts of France, the revocation of the Edict of Nantes was attempted to be enforced. Court de Gébelin derives the word from *camisade*, a night attack (*Hist. des troubles des Cévennes*, 3 vols. 1760). Louvreleuil, in his *Le Fanatisme Renouvelé*, 1704, suggests its connection with the *camise*, or linen shirt, at one time worn by the insurgents as a uniform, and with *camis*, a road-runner. The Camisards were also called Barbets (or water-dogs, a term also applied to the Vaudois), Vagabonds, Assemblers (*assemblée* was the name given to the meeting or conventicle of Huguenots), Fanatics, and the Children of God. They belonged to that romance-speaking people of Gothic descent who took part in the earliest movements towards religious reform. It was in Languedoc that the Peace of God and the Truce of God were formed in the 11th century against the miseries of private war (Rudolph Glaber, iv. 5). There were preserved the forms of municipal freedom which nearly all Europe had lost; and there commerce flourished without spoiling the thrift, the patience, the simplicity of the national character Not even the voluptuous court of Arles, with its trouvères, its courts of love, and its extravagant applications of the rules of chivalry, could corrupt the free and honest intelligence of these southern communities. Before the tragedy of the Albigenses began, it was a proverb in Languedoc against the stupid and sensual priesthood, "J'aimerais mieux être prêtre que d'avoir fait une telle chose." Although the rage of the Crusaders and the cold hate of the Dominicans were successful in blasting the commercial development of the district, they could not wholly eradicate those ideas which, whether called Paulician, Catharist, Bulgarian, Hussite, or Protestant, really represent religious sincerity and mental freedom. Calvin was warmly welcomed when he preached at Nîmes, Montpellier became the chief centre for the instruction of the Huguenot youth. But it was in the great triangular plateau of mountain called the Cévennes that, among the small farmers, the cloth and silk weavers, and vine dressers, Protestantism was most intense and universal. These people were and still are very poor, but they are intelligent and pious, and they add to the deep fervour of the Provençal character a gravity which is probably the result of their recorded history. From the lists of Huguenots sent from Languedoc to the galleys (1684 to 1762), we gather that the common type of *physique* is "belle taille, cheveux bruns, visage ovale." The diocese of Meude consists of 173 parishes, and contains the Bas Gévaudan and the Haut Gévaudan. The Haut Gévaudan consists of the Mountains la Marguerite and Aulrac; the Bas Gévaudan embraces the Hautes Cévennes and the Lozère. In the midst of these mountains are three great plains or plateaux, called respectively L'Hôpital, L'Hospitalet, and La Cause, and a forest named Le Faux des Armes. Barley and chestnuts are the chief products of Gévaudan. The Basses Cévennes are in the richer diocese of Alais, which has 93 parishes. The chief mountains are Aigoal and Esperon, the latter enclosing a beautiful plateau named Hort-Dieu (God's Garden). The Vivarais lies in the diocese of Viviers, which has 314 parishes and 3 cantons; Boutières, Montagne, and Bas-Vivarais. Farther south are the well-cultivated dioceses of Uzes, Nîmes (called Little Canaan), and Montpellier, the last of which is connected with La Serrane, the southern branch of the Cévennes. The whole district of the war is thus contained in the modern departments of Lozere, Aveyron, Drôme, Ardèche, Gard, and Hérault.

To understand the war of these Camisards requires a glance at the preceding history of France. The system of toleration which was established under the Edict of Nantes, 13th April 1598, and the Edict of Grace (Nimes), July 1629, was essentially a political compromise, and not a recognition of the principle of religious equality. The right of having a private chapel was given to all *seigneurs de fief haut justicier*, but in the case of a *seigneur sans haute justice* only thirty persons might attend the service. New public churches were to be authorized at a certain rate in certain places. On the other hand, Calvinists were admitted to all public posts and to all professions: they could publish books in towns where they had churches. The Chamber of the Edict was formed in the parliament of Paris for the impartial judgment of cases brought by Huguenots; and the "mi-partie," half-Catholic half-Protestant constitution, was adopted in the town-consulates and the local parliaments of the south. After the short-lived struggle between Louis XIII. and the Duc de Rohan, the Huguenots settled down into contented industry; the army and navy of France were led by two Huguenots, Turenne and Duquesne, and Cardinal Bentivoglio wrote to Pope Paul IV. that he no longer found in France "quell' insano fervor di coscienza si radicato primo negli ugonotti." But the court in which Mme. de Maintenon had succeeded to Mme. de Montespan, where Louvois and the Jesuit Père la Chaise were as supreme as Bossuet and Fléchier in the church, could not long be satisfied with tolerated heresy, which they chose to consider as veiled rebellion.

On the death of Mazarin a commissioner had perambulated the kingdom to inquire into the titles, or rather to suppress as many as possible, of the Huguenot churches, schools, and cemeteries. The extirpation of heresy had, in fact, been provided for by a clause in the marriage-contract between Louis and Maria Theresa (1660), and in spite of the protection of Colbert, a policy was begun of destroying piece-meal the privileges of the dissenters. The chancellor Le Tellier, by a series of arbitrary council edicts, shut against them the public offices and the trade corporations, forbade them to marry with Catholics, and encouraged, almost enforced, the conversion of children who had reached the age of seven. The wholesale briberies of Pélisson, the destruction of churches by Foucault in Montauban, Béarn, and Poitiers, the billeting of soldiers on the unconverted in Languedoc by the intendant Bâville, led up the Edict of Revocation (18th October 1685). This edict directed all the churches to be destroyed, forbade religious meetings under pain of imprisonment and confiscation of goods, ordered all ministers or pastors (who would not change their faith) to be banished within fifteen days, and to stop preaching at once under pain of the galleys, promised several exemptions from taxes and increased salaries to converted ministers, suppressed all Huguenot schools, and directed all children to be baptized and brought up in the Catholic faith, prohibited all Huguenots, except ministers, from going abroad, and declared the property of those who had already gone to be forfeited unless they returned within four months. Such was the formal scheme. In carrying it into effect, Huguenot Bibles, Testaments, Psalters, and books of religious instruction were burned, and Huguenots were forbidden to hire themselves as artisans or as domestic servants. Torture, hanging, insults worse than death to women, the galleys for life, imprisonment for life in the Tour de la Constance, near Aigues-mortes, were the ordinary occurrences of the next sixty years. Many escaped to Geneva, Lausanne, Amsterdam, and London. It is calculated that 600,000 French Protestants left their country in the twenty years following the revocation, and 400,000 in the twenty years preceding it (Smiles, *The Huguenots in France*, p. 17). Many suffered a shameful

conversion, but in the Cévennes the inhabitants were too poor to escape, and all over Languedoc began the secret meetings of the Church of the Desert. At last Louvois proposed that this rebellious district should be turned into an actual desert. The intendant Bâville and the Duc de Noailles raised an army 40,000 strong, and erected forts at Nîmes, St Hippolyte, Alais, and Anduze. The peace of Ryswick (1697) facilitated these operations. The religious hysteria which now descended on the Cévennes has been traced (*De l'Inspiration des Camisards*, par Hippolyte Blanc, Paris, 1859) to Du Serre, an old Calvinist of Dieu-le-fit, who, in reading Jurieu's well-known book on the *Fulfilment of the Prophecies*, became suddenly inspired to preach and pray, and who about 1689 communicated his enthusiasm to the shepherdess La Belle Isabeau, and 500 or 600 other so-called prophets.

In 1700 this sacred fire again broke out in the person of a travelling dressmaker in Ardèche, and spread from the summits of the Lozère to the sea (Peyrat, *Histoire des Pasteurs du Désert*, i. 261). A woman (Isabel Vincent) was again the most exalted of the prophets. The Abbé du Chaila, a veteran Catholic missionary from Siam, had been appointed inspector of missions in the Cévennes. There he introduced the "squeezers" (which resembled the Scotch "boot"), and his systematic and refined cruelty at last broke the patience of his victims. His murder, on 23d July 1702, at Pont de Mont Vert, was the first blow in the war. It was planned by Esprit Séguier, the "Danton of the Cévennes," who at once began to carry out his idea of a general massacre of the Catholic priests. He soon fell, and was succeeded by Laporte, an old soldier, who, as his troop increased, assumed the title of the Colonel of the Children of God, and named his camp the "Camp of the Eternal." He used to lead his followers to the fight, singing Clement Marot's grand version of the 68th Psalm, "Que Dieu se montre seulement," to the music of Goudimal. Besides La Porte, the forest-ranger Castanet, the wool-carders Conderc and Mazel, the soldiers Catinat, Joany, and Ravenel were selected as captains,—all men whom the *théomanie* or prophetic malady had visited. But the most important figures are those of Roland, who afterwards issued the following extraordinary despatch to the inhabitants of St André :—"Nous, comte et seigneur Roland, généralissime des Protestants de France, nous ordonnons que vous ayez à congédier dans trois jours tous les prêtres et missionaires qui sont chez vous, sous peine d'être brûlés tout vifs, vous et eux" (Court, i. p. 219); and Jean Cavalier, the baker's boy, who, at the age of seventeen, commanded the southern army of the Camisards, and who, after defeating successively Count de Broglie and three French marshals, Montrevel, Berwick, and Villars, made an honourable peace.[1]

Cavalier for nearly three years continued to direct the war. Regular taxes were raised, arsenals were formed in the great limestone caves of the district, the Catholic churches and their decorations were burned, and the clergy driven away Occasionally routed in regular engagements, the Camisards, through their desperate valour, and the rapidity of their movements in a country without good roads, were constantly successful in skirmishes, night attacks, and ambuscades. A force of 60,000 was now in the field against them; among others, the Irish Brigade which had just returned from the persecutions of the Vaudois. Montrevel adopted a policy of extermination, and 466 villages were burned in the Upper Cévennes alone, the population being for the most part put to the sword. The Pope, Clement XI., assisted in this glorious work by issuing a Bull against the "execrable race of the ancient Albigenses," and promising remission of sins to the holy militia which was now formed among the Catholic population, and was called the Florentines, Cadets of the Cross, or White Camisards. Villars, the victor of Hochstadt and Friedlingen, saw that conciliation was necessary; he took advantage of the feeling of horror with which the quiet Protestants of Nîmes and other towns now regarded the war, and published an amnesty. In May 1704 a formal meeting between Cavalier and Villars took place at Nîmes. The result of the interview was that a document entitled *Très humble requête des réformés du Languedoc au Roi* was despatched to the court. The three leading requests for liberty of conscience and the right of assembly outside walled towns, for the liberation of those sentenced to prison or the galleys under the revocation, and for the restitution to the emigrants of their property and civil rights, were all granted,—the first on condition of no churches being built, and the third on condition of an oath of allegiance being taken. The greater part of the Camisard army under Roland, Ravenel, and Joany would not accept the terms which Cavalier had arranged. They insisted that the Edict of Nantes must be restored,—"*point de paix, que nous n'ayons nos temples.*" They continued the war till January 1705, by which time all their leaders were either killed or dispersed.

In 1709 Mazel and Claris, with the aid of two preaching women, Marie Desubas and Elisabeth Catalon, made a serious effort to rekindle revolt in the Vivarais. In 1711 all opposition and all signs of the Reformed religion had disappeared. On 8th March 1715, by medals and a proclamation, Louis XIV. announced the entire extinction of heresy. Fourteen years afterwards, in spite of the strictest surveillance, aided by military occupation whenever the exigencies of foreign war permitted, the heroic missionary Antoine Court had organized 120 churches in Languedoc, which were attended by 200,000 Protestants, and governed secretly by the old discipline of "pasteur, anciens, consistoire, synode;" the Society of Help for the Afflicted Faithful (to which George I. subscribed 500 guineas a year) had established their training college at Lausanne; and during the next thirty years Paul Rabaut, minister at Nîmes, fostered and developed this religion, the child of intolerance. Voltaire's intervention in the affair of Calas stopped further religious persecution of an extreme kind;[2] but it was not till 1775 that the last galley slaves from Languedoc were liberated, and not till 1789 that, on the motion of Rabaut St Étienne, the son of Paul Rabaut, the National Assembly repealed the penal laws against Protestants.[3] The sufferings of the Cévénols on the galleys ("Forçats pour la Foi," as they were called) have been described in the *Mémoires de Marteilhe de Bergerac*, Rotterdam, 1757 (translated into English by J. Willington, 1758, 2 vols.); in Bion's *Relation des tourments que l'on fait souffrir aux Protestants sur les galères de France*, London, 1708; in the *Discours sur la Providence*, by Louis de Marolles, which is translated into English; and in the *Histoire de l'Honnête Criminel*, the autobiography of Jean Fabre. M. Athanase Coquerel the younger published in 1866 an *Historical Study* on the subject.

[1] Cavalier afterwards entered the British army, fought at the battle of Almanza, and died governor of Jersey in 1740. He told Voltaire that the discipline of his troops was maintained by a prophetess, La Grande Marie, who condemned to death all insubordinates. *Siècle de Louis XIV.*, c. 36. See also *Memoirs of the Wars of the Cévennes*, by Jean Cavalier, London, 1726; and the documents in *Jean Cavalier, ou les Fanatiques des Cévennes*, Paris, 1840, 4 vols.

[2] Voltaire procured the release of several Huguenot galley slaves, among others Chaumont, the shoemaker. After the treaty of Utrecht Queen Anne persuaded the French Government to free about 146; the total number was about 1500.

[3] There was an indecisive Edict of Toleration by Louis XVI. in 1787.

What we know of the spiritual manifestations in the Cévennes (which much resembled those of the Swedish Raestars of Smaland in 1844) is chiefly derived from *Le Théâtre Sacré des Cévennes*, London, 1707, reprinted at Paris in 1847; *A Cry from the Desert*, &c., by John Lacy, London, 1707; *La clef des prophéties de M. Marion*, London, 1707; *Avertissements prophétiques d'Elie Marion*, &c., London, 1707 About the date of these publications Marion, Durand Fage, and Cavalier were in London. They tried to propagate their "mystical phalanx" there, but the consistory of the French church in the Savoy pronounced the "ecstasy" to be an assumed and voluntary habit. Voltaire relates (*Siècle de Louis XIV.*, c. 36) that Marion wished to prove his inspiration by attempting to raise a dead body from St Paul's churchyard. He was at last compelled to leave England. The inspiration (of which there were four degrees, *avertissement, souffle, prophétie, dons*) was sometimes communicated by a kiss at the assembly. The patient, who had gone through several fasts three days in length, became pale and fell insensible to the ground. Then came violent agitations of the limbs and head, as Voltaire remarks, "quite according to the ancient custom of all nations, and the rules of madness transmitted from age to age" Finally the patient (who might be a little child, a woman, a half-witted person) began to speak in the good French of the Huguenot Bible words such as these: "Mes frères, amendez-vous, faites pénitence, la fin du monde approche; le jugement général sera dans trois mois; répentez-vous du grand péché que vous avez commis d'aller à la messe; c'est le Saint-Esprit qui parle par ma bouche" (*Histoire du fanatisme de notre temps*, par Brueys, Utrecht, 1737, vol. i. p. 153). The discourse might go on for two hours; after which the patient could only express himself in his native patois,—a Romance idiom,—and had no recollection of his "ecstasy." All kinds of miracles attended on the Camisards. Lights in the sky guided them to places of safety, voices sang encouragement to them, shots and wounds were often harmless. Those entranced fell from trees without hurting themselves; they shed tears of blood; and they subsisted without food or speech for nine days. The supernatural was part of their life. Much literature has been devoted to the discussion of these marvels. The Catholics Fléchier (in his *Lettres Choisies*) and Brueys consider them the product of fasting and vanity, nourished on apocalyptic literature. The doctors Bertrand (in his *Du Magnetisme Animal*, Paris, 1826) and Calmeil (in his *De la Folie*, Paris, 1845) speak of magnetism, hysteria, and epilepsy, a prophetic monomania based on belief in divine possession. The Protestants Peyrat and Court are content with the phrase "ecstasy," and do not invoke the supernatural. The Catholic Tories, such as M. Hippolyte Blanc, regard the whole thing as the work of the devil. Since the publication of Hecker's work on *Epidemics of the Middle Ages*, it has been possible to consider the subject in its true relations.

Although the Camisards were guilty of great cruelties in the prosecution of the war, there does not seem to be sufficient ground for the charge made by Marshal de Villars: "Le plupart de leurs chefs ont leurs demoiselles" (letter of 9th August 1704, in the *War Archives*, vol. 1797). There probably were many cases in which a vicious use was made of the opportunities afforded by war and religious excitement; but the charges of sexual immorality rest chiefly on the worthless statements of Louvreleuil. The standard works relating to the Camisards are,—Elie Bénoît, *Historie de l'Édit de Nantes;* C. Coquerel, *Histoire des Églises du Desert;* and the work of Court, already mentioned.

Among the contemporary relics of this interesting period ought to be noticed *Lettre sur l'État present des Églises réformées de France*, Au Desert, Chez Pierre le Sincère. The author proves from the letter of Louis XIV. to the Elector of Brandenburg, 6th September 1666, that the king admitted that the Huguenots were loyal subjects, and had even given remarkable proofs of loyalty. He contrasts the passivity of his friends with the political intrigues of the Polish Socinians, and with the turbulence of the Swiss Anabaptists. Claude, in his *Plainte des Protestans cruellement opprimés dans le Royaume de France*, Cologne, Chez Marteau, 1686, gives a vivid picture of the persecution from the beginning. He mentions the "Explications," or official glosses on the edicts, of which the Jesuit Meynier was the most prolific author, one of which maintained that the Edict of Nantes (contrary to its express terms) was confined to Huguenots in life at its date; another, that the phrase *Petite École* did not include any school in which Latin was taught. He inveighs against the duplicity of the *Conseil*, who professed sometimes to blame, sometimes to encourage their intendants, and of the king, who in his circulars to the clergy declared (down to the moment of revocation) that he did not wish to interfere with the edicts. Soulier in his *History of the Edicts of Pacification*, and Nicole in his *Protestants convicted of Schism*, justified the royal policy from Scripture, history, and reason. Maimbourg in his *History of Pope Gregory*, and Varillas in his *History of Religious Revolutions in Europe*, praise Louis for using only the weapons of charity and persuasion. Translations of the narratives of John Bion, and of the anonymous friend of the martyr Louis de Marolles, were published together at London in 1712. The latter is dedicated to Heinsius, Pensionary of Holland and West Friesland, who had assisted the refugee Camisards; it is preceded by a violent preface, in which the author, an English clergyman, points out how the position of France has altered since the Peace of Ryswick, and urges the English intervention to restore the Edict of Nantes. For the politics of the subject he refers to *The Interest of Europe with respect to Peace or War*, London, 1712. Bion's narrative contains all the details about the galleys. *The Complete History of the Cevennes by a Doctor of the Civil Law*, London, 1703, consists of an account of the people and country by an Englishman who had lately travelled there, and of a separate historical survey, description of the edicts, and political argument. The doctor also prints the pretended *Manifesto of the Cevennois to the Dauphin*, and a form of prayer used in the Camisard Assembly. *The Memoirs of Jean Cavalier* are written in a very simple and picturesque style. One object he had in writing was to contradict the statements of Père Daniel. The *Théâtre Sacré des Cevennes* consists of the depositions of twelve witnesses (including Marion, Fage, Cavalier, Portales, Dubois) sworn on 6th March and 1st April 1707, before John Edisbury and Sir Richard Holford, both Masters in Chancery. The *Théâtre* also contains important extracts from the works of Bénoît, Brueys, Guiscard, and Boyer, and several original letters from Camisards. The same desire to protect the refugees from the attacks of the French Savoy Church in London, led to the publication of the *Mélange de litterature historique et critique sur tout ce qui regarde l'état extraordinaire des Cevennois*, London, 1707; and of a full account of the proceedings in the Consistory and Assembly against Jean Lions, one of the faithful ministers. The former contains excerpts from a *Dissertatio de justitia armorum Cebennorum* by Ernest Plane, Frankfort, 1704, which speculates about a supposed Camisard medal, turning out afterwards to be a Swedish dollar; the letters C R S (which the German savant translated Christus Rex Solus) meaning only Carolus Rex Sueciæ. (W. C. S.)

CAMOENS (or, according to the Portuguese spelling, CAMÕES), LUIZ DE (1524–1579), the son of Simão Vaz de Camoens and Ana de Sá e Miranda, was descended in the female line from the Gamas of Algarve, with which family Vasco de Gama claimed kinship; on the male side also the Camoens were of gentle birth and high social position. Lisbon, Coimbra, Alemquer, and Santarem have claimed to be the cradle of this "prince of poets of his time;" the balance of evidence, however, is now generally considered to be in favour of Lisbon. Manoel Correia, who was on terms of intimacy with the poet, in his *Commentaries on the Lusiad*, states: "The author of this book is Luiz de Camoens, Portuguese by nationality, born and bred in the city of Lisbon, of noble and accredited parentage." Correia states in his notes to canto 10 of the *Lusiad*, that Camoens was more than forty years of age when he wrote it; and, further on, that the canto was written in 1570. The evidence of Faria e Sousa, extracted in 1643 from the registers of the "India House at Lisbon," proves Camoens to have been twenty-five years of age in 1550; and 1524 is now generally accepted as approximately the year of his birth.

Alarmed by the shock of an earthquake as early as 1526, the court removed to Coimbra, where it remained until the pestilence, which devastated Lisbon and the border lands of the Tagus, had moderated; the nobles and "fidalguia" followed the king and court. Simão Vaz de Camoens having house and possessions at Coimbra, would naturally follow the court there with his family; the more so as his brother Bento had, prior to 1527, taken "the habit in the monastery of Santa Cruz," where he was often visited by the king. Evidently a man of culture, he was chosen, on the reformation of the university in 1529, "being then prior of his order," the first chancellor. The popularity of the training at the newly-reformed university drew within its walls most of the sons of the nobility and "fidalguia." Here Camoens was entered as one of "the honourable poor students" in 1537, remaining there until he had completed his eighteenth year. Of his manner of life during the period which intervened between his removal to Coimbra and the commencement of his university career, something may be gathered from his minor writings, from which it appears that he wandered by Mondego's banks, "careless and unfettered in the free licence of boyhood."

The position of the poet's uncle, Dom Bento de Camoens, as prior of Santa Cruz, in addition to his status as chancellor of the university, naturally suggested the church as a career for Camoens. This seems to have found no favour with him, as he writes, "I felt the pulse of many states of life. The clergy, I see, take stronger hold of life than of the salvation of souls; and the monks, although shrouded in hood and habit, expose some small tokens inconsistent with the profession that he who turns his back upon the world for God should desire nothing that the world can give." Freely and injudiciously expressed at an inopportune moment in the ardour of youth, such home truths would tend to mar his advancement in church or state; while his honesty, culture, wit, poetic genius, and comely appearance would induce much jealous enmity at a court where he was the idol of the women.

During his studentship, and possibly at a vacation revel, or when some degree was conferred, the students acted his *Amphitriões* in imitation of Plautus. The dramatic representations at the university had usually been of the tragedies of Seneca, or of original Latin compositions. This work of Camoens, in popular "redondilhos," and in the vernacular, was considered an attempt to popularize a poetic reaction which satirized the mode in which the grave doctors of the university desired that all instruction should be imparted. In a satire of Resende's, "to Luiz Camoens, reprehending those who, despising the learned, waste their own time with jesters," he indicates Camoens "as a pitiful poet, an unlucky monster, boasting to be a Latin bachelor."

With reference to the precise period when Camoens removed entirely from his *alma mater* and became again resident in Lisbon, some speculations have been hazarded by his biographers. The one carrying the most weight is cited by the Visconde de Juromenha, who founds it upon the statement made by the poet in his first letter from India: "Because, when I reflect that without sin, which would sentence me to thirteen days of purgatory, I have passed thirteen thousand caused by evil tongues." Upon this Juromenha observes: "These thirteen thousand days are equal to eight years and eight days, and deducting the two years Camoens passed in Ceuta, and the one year of banishment on the upper Tagus, this leaves 1542 as the year of his departure from Coimbra." Thus we find Camoens quitting college to return to the court at Lisbon in his eighteenth year. A French biographer has assumed, with some force, that "Corte" simply means Lisbon, and not the court; for as Camoens was not of the titular nobility, he would not be received at court. Contemporary evidence, on the other hand, rather favours the assumption that being of the "fidalguia," gentle born, and well cultured, he would be chosen as companion by many of the young nobles who were his fellow-students at Coimbra.

Gentleness of birth, classical attainments of no mean order, a cultivated intellect, and poetic genius, united to a pleasing personal appearance and witty manner, must have been good passports to the court of John III., in which resided at that time the Infante Dom Luiz, a man of considerable attainments and a fair poet; also the Infanta Donna Maria, patroness of the Belles Lettres, surrounded by a bevy of fair damsels who could compose song, dirge, epigram, and roundelay, or jest with the quick wit of a Beatrice, and who, like her, knew many "merry tales" by heart. Statesmen, such as the Conde de Sortelha and the Conde de Vimioso, courtly poets, and fellow-students of Camoens at Coimbra, both in the full blaze of court favour, would gladly welcome to Lisbon so polished a youth as Camoens must at that time have been. Of this same court of John III. Gil Vicente writes, "It is a sea in which many fished, but found the pastime dangerous." Sá de Miranda also blamed "the economic error of herding together all the young nobility in Lisbon."

Here, no doubt, Camoens formed acquaintanceships if not friendships, and became quickly initiated into the mysteries of court life and manners. Precocious and born a poet, his facility in every style of versification, a mind stored with romances of chivalry as well as popular fiction, and the poetic lore then available in his own, the Spanish, Italian, and classical idioms, would, added to his youth and sprightly manner, render him popular with the gentler, and unpopular with the sterner sex. Abandoning in some degree the antiquated forms of composition in vogue, he introduced eclogues, songs, and sonnets, full of tenderness and beauty, after the manner of the Italian school. Montemayor and Sá de Miranda, both Portuguese, residing in Italy, had already adopted and naturalized to some extent the Italian form of pastoral poetry.

Here we must speak of Camoens's romantic passion for a certain high-born lady of the court. "The sweet unwitting cause" of so much detriment to his court advancement, and, if we are to credit his muse, of anguish to his heart, was a certain Donna Caterina de Ataíde in attendance upon the queen of John III. The anagram of Natercia for Caterina clearly indicates the lady's name, in addition to which an acrostic coupling the names of Luiz with Caterina de Ataíde, said to be by Camoens, puts the matter beyond all doubt. The tradition is that, on a certain Good Friday, Camoens for the first time encountered the lady's eyes at her devotions in the Church of the Chagas, Lisbon. That the wound proved deep and permanent there is abundant evidence in his *Rimas*.

The lady's father, Dom Antonio de Lima, held the office of chamberlain in the royal household, a certain Pero de Andrade de Caminha serving in a similar capacity the Infante Dom Duarte. Caminha was a poet of fair ability, and was probably jealous of the success of Camoens; in addition to which tradition asserts that Caminha himself, favoured by her father, aspired to the hand, if not the heart, of the Donna Caterina. We may infer that the lady was not ignorant of the effect her eyes wrought upon the author of the *Lusiad*; at any rate Caminha was jealous, and revenged himself in weak splenetic rather than satirical verse, while the lady's father employed his interest to mar the poet's prospects.

The precise cause which led to Camoens's banishment from Lisbon is not clear. The principal reason, no doubt, was his passion for the golden-tressed Caterina, but there

may have been in addition to this some unintentional contempt of the rigid court etiquette which hedged the royalty of that day; for it was the custom that lyric offerings intended for the ladies of the queen's court should first be submitted to the chamberlain, and then by him transferred to the chief lady in waiting, who handed the effusion to the queen,—she, in her turn, after perusal, passing the "burning lines of passion" into the hands of the damsel to whom they were addressed. Camoens, doubtless, would essay some safer and more secret mode of conveying his offerings to the lovely Caterina. The dislike of De Lima, and the jealousy of Caminha, aided by the indiscretion and free-lance life of Camoens, may have led to this mark of the royal severity. Whether such or other causes intervened, the fact remains that he was banished from the court. The precise locality to which he retired, however, still remains conjectural only. Adding the year of his banishment to the two years he was absent with the army of Africa at Ceuta, where, in a naval engagement with the Moors, a chance splinter destroyed the sight of his right eye, we find him again in Lisbon in 1550.

During the three years which intervened between Camoens's return from Ceuta and his embarkation for India in 1553, he seems to have led a careless and discreditable kind of life, consorting with the least reputable court gallants, and a certain dissolute ex-Franciscan friar, who had abandoned the cowl to adopt the *rôle* of a low comedian. Since he inherited the traditions of "fidalguia,"—candid, brave, impetuous, and crossed in love,—much of the free and careless life credited by tradition at this period to Camoens is reasonably accounted for, if it may not be condoned. At this period occurred the fracas which led to his imprisonment and subsequent embarkation for India. On the occasion of a grand procession at the festival of Corpus Christi, one of the king's equerries appears to have had a dispute with two masquerading companions of Camoens. The latter, unhappily intervening to defend one of these friends hardly pressed, wounded the equerry in the neck, his two friends escaping in the confusion. For this Camoens lay some time in prison, and was only pardoned upon the understanding that he should embark forthwith for India. Juromenha gives the full text of this pardon.

With reference to the poet's departure for India in March 1553, the indefatigable Faria e Sousa discovered the following entry on the books of the registry of the Lisbon India House:—"Fernando Casado, inhabitant of Lisbon, went in his stead Luiz de Camoens, son of Simon and Ana de Sá." His father did not offer himself as the customary surety, while it is seen from a document, dated the 7th of March that year, that he was still alive, and an inhabitant of Lisbon.

Camoens, in his first letter from India, alludes to his departure from his native city; and as he sailed out of the "golden-sanded Tagus" in the twilight, exclaimed in the bitterness of his heart, using the words of Scipio Africanus,—"Ungrateful country, thou shalt not possess my bones!"

The ship in which he sailed, the "San Bento," parted company with her consorts during a storm, and reached her destination in the same year, while her missing consorts did not anchor at Goa until the following spring. On landing at Goa, Camoens found the Viceroy Noronha preparing an expedition to act against the king of Pimenta, who had invaded the territories of the allies of Portugal. With this expedition sailed Camoens; and "after chastising the enemy," he says, "with little trouble, we destroyed the people trained to the use of the curved bow, punishing them with death and fire." He returned to Goa early in the following year, 1554.

The friendly terms upon which Camoens remained with the governor, and probably his disgust at the vice and venality rampant around him, induced him to join the expedition organized with a view to check the depredations of the Moorish rovers on the coast of Arabia. The commander, Menezes, received instructions to cruise on that coast where he expected to intercept the galleys sailing from Bassorah. The fleet cleared from Goa early in the year 1555; and, after seeking the Moorish galleys in vain, wintered at Ormuz. Returning in the following spring to Goa, Camoens, in canção 10, describes his unpleasant impressions of this voyage: "Here fate's most cruel chances led me; here in this lonely, sterile, sun-scorched land did Fortune will that part of my brief life be passed, and thus in fragments scattered lie throughout the world." Some of Camoens's biographers allude to the governor Barreto as one of his relentless persecutors. Juromenha, however, demurs to this, alleging that two intimate friends of Camoens then at Goa, in the most frank and decided language, laud Barreto as "a liberal obliging comrade, and one ever ready to overlook offences received." That Camoens was unpopular with the venal many, his expression "This land is the mother of great villains and the stepmother of honourable men" leaves little doubt. He came to uphold the honour of Portugal, and not to intrigue, brawl, and barter his soul for gold. His satirical exposure of the abuses so rife then in the Eastern dominions of Portugal will readily account for his numerous enemies, official and lay. Festivals, banquets, and dramatic representations inaugurated the governorship of Barreto. Camoens's pen was not idle. He wrote a comedy for the occasion, entitled *Filodemo*. Correia, who describes himself as "companion in the state of India, and a great friend of Camoens," happily secured either the original MS. or a copy, which is, or was, in the national library at Lisbon. It is entitled, *A Comedy made by Luis de Camoens, and represented in India during the governorship of Barreto, and in which the following characters figure, &c.*

Camoens's unpropitious star still dominated his fate. The vices rampant in Goa, the drunkenness, dicing, brawling, and cowardice, were notorious; and during these festivities, which lasted some weeks, were more pronounced than ever.

A certain satire, said to be from the pen of Camoens, passed from hand to hand, entitled *A Jest which was made upon some men who did not think ill of wine, feigning that in Goa, at the feasts which were made on the governor's succession, these gallants went to sport with canes bearing devices on their banners, and verses conforming to their designs and inclinations.* It is written chiefly in prose, having verses introduced. No names of the "gallants" appear. After introducing a few of these revellers, the author concludes by stating "that several other illustrious personages desired to be admitted to the feasts and sports, and to have an account of their qualifications chronicled;" but, he observes, "the writing would be infinite, because all the men in India are so distinguished, and therefore let these suffice as examples." This jest, intended to satirize the corruption and immorality of the daily life of the Portuguese in India, caused intense amusement to those who did not recognize their own portraits on the canvas; while, on the other hand, those who did, or imagined they did, were furious,—so much so, that "the innocent author remained ready to hang himself."

The tradition is that this *Jest* was appended to Camoens's second letter from India, and that the author desired its source should remain unknown; "because I do not wish that of my little so many should eat." Be that as it may, Camoens was banished from Goa, and this *Jest* is said to have been the cause. Some of those ridiculed

were powerful, malignant, and treacherous; and it is surmised that Barreto was of the number, but it is difficult to imagine that if Barreto intended punishment he should have made of this banishment a stepping-stone to a lucrative appointment, which must have been one of considerable importance, embracing as it did the custody of the property of absentees, and of those Portuguese who had died in India. In a letter from Francisco de Souza to John III. the importance of this office is recognized, grave complaints of embezzlement and misappropriation of the property of deceased merchants and others having reached Lisbon, so that, "early in 1556, a commission was despatched from the mother country to take charge of the effects of deceased subjects," and, in 1557, "full instructions as to the management of this state department followed." Barreto, with a laudable desire to abate these scandals, may well have appointed a bold energetic man, upon whose integrity he could rely, and Camoens was selected.

During the absence of Camoens from Goa his friend Luiz Franco Correia collected the verses he had scattered amongst his friends, shrewdly observing, "that they who knew not the poetic art failed to estimate its value."

Apart from the vices and intrigues of Goa, and in the quietude of the Grotto still shown at Macao as the spot where much of the *Lusiad* was penned, we may imagine halcyon days for the persecuted poet. Here Antonio, the Javanese slave, is first introduced to history,—he who tended Camoens so affectionately and with such solicitude through those latter years of misery and neglect, which were the lot of this unhappy "prince of poets of his time." It is surmised that the first six cantos of the *Lusiad* were composed during Camoens's stay at Macao; for in the seventh, allusion is made to the shipwreck he suffered on his return to Goa.

During his absence slanderous tongues were not silent, and we hear of his return to Goa by order of the governor, to make answer to charges brought against him in his capacity as commissary. Wrecked near the mouth of the River Mekong, Camoens and his faithful Javanese escaped only with their lives. Camoens, rescuing nothing but the manuscript of his epic, at length landed at Goa in the last days of Barreto's governorship, and was cast into prison. Here he received the only news which could aggravate his pain—the sad tidings of the death of Donna Caterina de Ataide, the Natercia of his impassioned youth. We can estimate the depth and tenderness of his grief touchingly expressed in many of the *Rimas*.

The arrival in the autumn of the following year of Dom Constantinho de Bragança as governor to replace Barreto led to the liberation of Camoens, the charges against him having been proved to be unfounded. Under the protection of Dom Constantinho the poet enjoyed some respite from his persecutors. It was during this period of "cultured calm" that he invited several "versifying friends" to a banquet, where each, on uncovering his plate, discovered, in place of the first course, an appropriate stanza. The surprise gave occasion to considerable mirth and amusement. Three years later Dom Constantinho was replaced by the Conde de Redondo, an early friend and companion of the poet's. Towards the close of 1562 Camoens suffered a new reverse. Miguel Rodriguez Coutinho, a rich braggart, nick-named Fios Seccos (dry threads), detained him in custody for a trifling debt. On this occasion Camoens sent a request to the Conde to release him, in epigrammatic verse, which well revenges Coutinho's meanness, commencing—"What devil so completely damned but fears the edge of Fios Seccos' sword." Camoens was released, but does not appear to have accompanied the viceroy and his splendid retinue to Zamorin. Being desirous to return to his native land, a certain Captain Barreto, nephew of the old governor of Goa, charmed with the society of the poet, agreed to carry him to Sofala; once there he hoped to detain him, and claimed a small sum he was unable to discharge. Here the expedition under Noronha, ex-governor of Goa, found him; and of Camoens's condition Diogo de Couto wrote: "Here we encountered that 'prince of poets of his time,' my fellow-sailor and friend, Luiz de Camoens, so poor that he lived upon his acquaintance, who found him necessary clothing and gladly gave him to eat. During that winter he prepared his *Lusiad* for the press, and wrote much in a book he called the *Parnaso of Luiz de Camoens.*"

The fleet, including the "Santa Clara," with Camoens on board, sailed from Sofala in November 1569, and on the 7th April 1570 the good ship cast anchor in the broad waters of the "golden-sanded Tagus."

After seventeen years of weary exile we may imagine the thrill of joy that warmed the heart of Camoens at the first sight of the headland which bares its base to the wash of the Atlantic, and marks the entrance to the Tagus. "From the round-top of the loftiest mast a sailor shouts, 'The land, the land!' This is my native land so fondly loved, which heaven grant, all perils past, my task accomplished, these eyes behold once more before their light be dimmed for ever." While others from the far Indies brought rich merchandize and gold, he who had suffered banishments and imprisonments, had encountered tempests and shipwreck, came freighted only with a single manuscript, on the pages of which were traced in immortal verse the glorious historic deeds of the Portuguese nation, and the touching episode of Ignez de Castro. Here Fortune still continued to persecute Camoens. He and his companions were not permitted to land, Lisbon having recently suffered from the effects of a pestilence which had destroyed 50,000 souls.[1]

Late in the month of April, the great plague having abated, a procession of our Lady of Health was decreed; and it is supposed that Camoens had already landed and embraced his mother, then "very old and very poor." The *Lusiad*, being now completed and ready for the press, after much delay and many impediments, was, through the influence of Dom Manoel, ambassador to Castile, presented in manuscript to the young king in the following year, 1571; the royal permission to print the work was accorded, the Alvará bearing date the 23d September of that year. Later the "censura" of the holy office was obtained, bearing date 12th March 1572. It carries the signature of Father Ferreira, a man of singular ability and evidently liberal views, and is as follows:—"I saw, by order of the Holy Inquisition, these ten cantos of the *Lusiad* of Luiz de Camoens, relating the valorous deeds in arms of the Portuguese in Asia and Europe, and I did not find in them a single offensive thing, nor aught contrary to the faith and good manners; only it seemed to me necessary to warn the reader that the author, in order to exaggerate the perils of the navigation and entrance into India of the Portuguese, makes use of a fiction of the heathen gods; and although San Agostinho in his *Retractações* corrects the having called the muses goddesses, nevertheless, as this is poetry and fiction, and the author does not pretend more than to adorn his poetic style, I have not considered it inconvenient this fable of the gods in this work, knowing it for such, and while is always preserved the truth of our Holy Faith, that all the gods of the heathen are devils, and therefore it appeared to me that the book is worthy of being printed.

[1] No record has been discovered of the death of Simão Vaz, father of the poet, but it is conjectured that he died of the plague during the autumn of 1569.

and the author displays in it much talent and erudition in the human sciences." The Lisbon upon which Camoens turned his back in 1553 had sadly changed; the times were out of joint. A dreadful pestilence had decimated the population; the intrigues inseparable from a regency, and a young king, the sport of youthful favourites, ruled by the Jesuits, brave and impetuous, already meditating the luckless expedition to Africa, overshadowed both court and kingdom. Remarking this, in his address to the young king Camoens wrote,—"The humility of the anchorite should not be the only virtue of your ministers."

At length the epic, dreamed of at Coimbra, commenced in banishment, continued at Ceuta, resumed at Goa and Macao, revised at Mozambique and Sofala, and perfected in a humble room in the Rua de Santa Ana, Lisbon, was issued from the press of Antonio Gõçalvez.

The first edition of the *Lusiad* bears date Lisbon, 1572. Its success was immense, and the despair and malice of the mediocre poets of the court intense. A second edition was issued from the press of Gõçalvez in the same year.

Isolated amid this literary strife, Camoens lived retired, and was very poor. He lived in the knowledge of many, and in the companionship of few, inhabiting an apartment in a house adjoining the convent Santa Ana, at the bottom of a small street which led to the college of the Jesuits, where the sole consolation of his later years was his intimacy with some of the fathers. By the death of the Princess Donna Maria, who expired in 1578, Camoens lost the last of his protectors, and was reduced to extreme poverty; then came the heaviest blow of all, the death of his faithful Javanese Antonio.

Early in the year 1578, after the grand ceremony of the Benediction of the Standards, Dom Sebastião, the boy king, departed on his ill-starred expedition to Africa,—Bernardes, a court poet and a courtier, being selected in preference to Camoens to accompany the expedition and sing its triumphs. In August occurred the fatal rout of Alcazar-quivir, and the death of the young king, after which, according to the testimony of Bernardo Rodriguez, "Camoens went as one dreaming."

Three months prior to the poet's death, Benito Caldera's Castilian version of the *Lusiad* was printed at Alcalá de Henares, and we may reasonably infer that Camoens saw a copy."

The disaster of Alcazar-quivir shook Portuguese nationality to its base. In the last letter Camoens penned he alludes to this event. "I have so loved my country that not only do I deem myself happy to die in her bosom but happy to die with her.

The sad sickness unto death came at last, on the 10th of June, 1580. In a small, cheerless room of a shabby house in the Rua de Santa Ana (No. 52 or 54) Luiz de Camoens died, and he was buried in the neighbouring convent of Santa Ana. On the fly-leaf of a copy of the first edition of the *Lusiad* (said to be in the library of Holland House), and in the handwriting of Fray José Indio, a Carmelite monk of Guadalajara, is found the following statement:—

> "What thing more grievous than to see so great genius lacking success! I saw him die in a hospital in Lisbon, without a sheet to cover him, after having triumphed in the Indies, and having sailed five thousand five hundred leagues by sea. What warning so great for those, who, by night and day, weary themselves in study without profit, like the spider weaving a web to catch small flies."

Some picturesque and touching, but probably apocryphal narratives are chronicled by Camoens's biographers. One tells of the faithful Javanese Antonio sallying forth at eventide to beg from passers-by the means to procure a modest meal for himself and his master; another, of Barbara, a mulatto woman, who, from the scanty store upon her stall and the still scantier treasury of her pocket, spared a daily ration and an occasional silver coin in pity for one she might have known prosperous at Macao; and a third of a "fidalgo," named Ruy Diaz de Camara, who came to his poor dwelling to complain of the non-fulfilment of a promise of a translation of the penitential psalms, and to whom Camoens replied—"When I wrote verses I was young, had ample food, was a lover, and beloved by many friends and by the ladies; therefore, I felt poetic ardour. Now I have no spirit, no peace of mind; behold there my Javanese who asks me for two coins to purchase fuel, and I have none to give him." On his deathbed he is said to have exclaimed, "Who ever heard that on so small a stage as a poor bed, Fortune should care to represent so great misfortune, and I, as if such were not sufficient, place myself on her side, because to dare to resist such ills would appear effrontery."

Camoens was spared the pain and humiliation of seeing a Castilian king upon the throne of Portugal. It is, however, related of Philip II. that, soon after his occupation of Lisbon, he inquired for Camoens, and finding him already dead, gave (as documentary evidence shows) instructions that a pension be granted to the poet's mother, still "very old and very poor." She survived the poet some years.

Of Camoens's personal appearance Manoel Severim de Faria, one of his biographers, writes thus: "He was of middle stature, his face full, and his countenance slightly lowering; his nose long, raised in the middle, and large at the end. He was much disfigured by the loss of his right eye. Whilst young his hair (like Tasso's) was so yellow as to resemble saffron. Although his appearance was not perhaps prepossessing, his manners and conversation were pleasing and cheerful. He was afterwards a prey to melancholy, was never married, and left no child." On a marble slab fixed in the wall of the church of Santa Ana, Dom Gonçalo de Coutinho had an inscription placed; but as both church and inscription perished in the earthquake of 1755, there is some doubt as to its precise wording, and whether "he lived poor and neglected and so died" formed part of it or not.

Amid many tributes to Camoens's memory, those of Manoel de Sousa, Diogo Bernardes, Tasso, and Lope-de-Vega are well known. The last alludes to him as "the divine Camoens," and adds, "Strange fortune that to so much wit and learning gave a life of poverty and a rich sepulchre."

A Spanish biographer of Cervantes has shown "that the most remarkable coincidence of fortune may be traced in the events which marked the lives of Camoens and the author of *Don Quixote*."

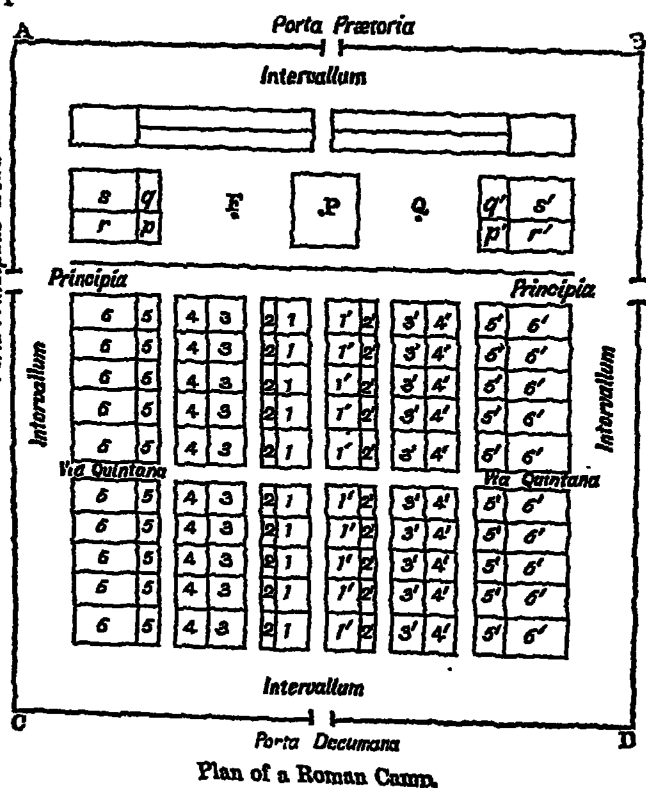
Estimating the popularity of Camoens great epic *Os Lusiadas* by the number of editions printed in Portugal, it was without question considerable, no less than thirty-eight having been published at Lisbon prior to the year 1700, and in addition four in Spain,—three in Castilian and one in Portuguese. There exist translations in English, French, German, Italian, Dutch, Polish, Bohemian, Danish, Swedish, Russian, Latin, Greek, and even Hebrew. The earliest in English is by Sir Richard Fanshaw (London, 1655), and was composed during his banishment at Tankersley Park, Yorkshire, in 1652. Had he lived to prepare a second edition, many errors and imperfections arising from an incomplete knowledge of the Portuguese idiom would, no doubt, have been rectified. He was appointed ambassador to Portugal in 1661, where he remained three years, being then transferred to Madrid, where he died in 1666. Mickle's *Lusiad* was first published in 1776, and hardly merits Southey's condemnation (he preferring that of Fanshaw) of "most unfaithful." It is fairly close in places, but much of the force of the original is sacrificed for the sake of smooth versification. Another translation by Musgrave in blank verse appeared in 1826, the latter cantos of which are closer and more effective than the earlier. A version of the first five cantos by Quillinan followed in 1853, rendered with considerable grace and with greater accuracy than Mickle's. In 1854 appeared a version by Sir Thomas Mitchell.

In estimating the genius of Camoens, it must be remembered that "we build with ready materials, but he dug the quarry, rough-

hewing and polishing with his own hands the material for his edifice." He strengthened and polished the Portuguese language, and his influence preserved it from destruction as an idiom during the Spanish occupation, when the language of the court was Castilian. The circumstances under which his great epic was penned were peculiarly unfavourable to the production and elaboration of such a work; still he triumphed over every difficulty, and produced the epic master-piece of his age. Theophilo Braga, his latest Portuguese biographer, observes, "In Camoens we find exemplified that tradition which insures moral unity to a people, and is the bond which constitutes their nationality, as in the Homeric poems are centered the Hellenic traditions. This same spirit animated Camoens, for in *Os Lusiadas* are gathered together many beautiful and exciting traditions of Portuguese history." Extended and elaborate notices of the *Lusiad* will be found in Adamson, Mickle, and Bouterwek.

Of Camoens's minor works, or *Rimas*, a full and exhaustive notice will be found in *Memoirs of the Life and Writings of Luis de Camoens*, by John Adamson, London, 1820; two exquisite trifles (the originals in Spanish) will be found in Ticknor's *History of Spanish Literature*. Lord Strangford, Adamson, Hayley, and Southey have each translated striking examples of the *Rimas*. (F. W. CO.)

CAMP, Roman. While the Greeks, depending more upon the advantages of situation, adapted the form of their encampment to the nature of the ground selected, the Romans laid out theirs according to a fixed and definite plan, modified only by the numbers for whom accommodation had to be provided. Its form and arrangement in the best days of the republic are minutely and clearly described by Polybius, the companion in many wars of the younger Scipio.



Plan of a Roman Camp.

A Roman camp of the Polybian type was intended primarily to accommodate a consular army, consisting of two legions, each of 4200 infantry and 300 cavalry, with the ordinary contingent of "socii," amounting in all to 16,800 foot and 1800 horse and for this purpose it was pitched in the form of a square, each side of which extended 2017 Roman feet in length. This square was divided into two unequal portions by a perfectly straight road called the "principia," 100 feet in breadth, running parallel with the front and rear of the camp, and forming at its extremities in the sides AC and BD of the camp two gates, the "porta principalis dextra" and the "porta principalis sinistra." In what may be called the upper and smaller portion, determining the arrangement of the rest of the camp, stood the "prætorium" (P), or general's tent, so situated as to have a commanding view in all directions. 100 feet of clear ground on every side left the "prætorium" in the centre of a square, whose sides, each 200 feet in length, were carefully traced parallel to the sides of the camp. To the right and left of the "prætorium," at F and Q, were the "forum," or market-place, and the "quæstorium," or paymaster's tent. Further to the right and left, at (p, q), (p', q'), (r, s), (r', s'), were stationed the cavalry and infantry that formed the bodyguard of the consul and quæstor. Fifty feet in front of the "prætorium," along the line forming the upper boundary of the "principia," were the tents of the twelve tribunes of the legions, six to the right and six to the left of the "prætorium," opposite their respective legions. In the prolongation of the same line were probably stationed the "præfecti sociorum." Passing from the upper to the lower division, or to what was called the front of the camp, we cross the "principia," the great thoroughfare of the army, where the standards of the legion were placed round the altars of the gods. This part of the camp, *i.e.*, between the "principia" and the side CD, was allotted to the main body of the army. It was intersected transversely in the middle by a street 50 feet broad, the "via quintana," as well as longitudinally by what were called the "viæ" or streets of the camp. Each of the latter was also 50 feet in breadth, and the central "via" formed the boundary between the two legions, which were placed symmetrically to the right and left on each side. The "equites," "triarii," "principes," and "hastati" of the legion were stationed in the spaces numbered (1, 1′), (2, 2′), (3, 3′), (4, 4′),—each of the spaces devoted to the cavalry containing, within an area of 10,000 square feet, one squadron of thirty men and horses, while in the same area there were quartered of the "principes" and "hastati" two "maniples" or divisions of sixty men each. Each of the spaces where the "triarii" were stationed was only half this area, and devoted to one "maniple" of sixty men. Spaces (5, 5′), (6, 6′) were assigned to the cavalry and infantry of the allies, of whom, however, a part was quartered in the upper camp. The "velites" (light-armed troops) were probably distributed proportionally among the three-divisions of the infantry. Between the tents and outer wall of the camp there was an "intervallum" all round, 200 feet broad, by which ample room was given for the passage of the legions in and out, and which also served as a receptacle for booty, as well as to increase the distance of the troops from the enemy. The camp was provided with four gates—(1) "porta principalis dextra," and (2) "porta principalis sinistra," at the extremities of the "principia;" (3), "porta prætoria," on the side nearest the "prætorium," and in the very centre of that side; (4), "porta decumana," in the centre of the side opposite. The fortifications consisted of a fosse or ditch (*fossa*), 9 feet deep and 12 feet wide, the earth from which, as it was dug out, being thrown to the inside, formed, with the addition of turf and stone, a mound (*agger*), on the summit of which were fixed stout wooden stakes (*sudes*).

Such was the general outline of the Polybian camp; but when, under the emperors, changes were made in the constitution of the army, and organization by cohorts was introduced, the form and disposition of a Roman camp underwent modifications that resulted in what has been called the Hyginian camp, from Hyginus, a land surveyor who flourished under Trajan and Hadrian, and who has given an account of its arrangement in his day. The principal points of contrast with the Polybian camp were, that the form was now oblong and did not occupy half so much space, that the troops were stationed in cohorts round the rampart so as to enclose the whole body of foreigners and baggage, and that the fortification was much less substantial.

The ordinary entrenchments thrown up from day to day by a Roman army while on the march were but slight

but, where it was necessary or expedient to remain together for some time, or where it was likely they might reoccupy the same ground, a more permanent camp, with a proportionably stronger rampart, was formed. Such an encampment was called "castra stativa," or a stationary camp. This, again, was distinguished as "castra æstiva," a permanent summer camp, and "castra hiberna," a permanent winter camp. Such were the camps that, in process of time, becoming surrounded by a numerous population, formed the nucleus of large towns, many of which may be recognized in England by the name-termination "chester" or "cester."

CAMPAGNA, a town of Italy, in the province of Principato Citeriore, 19 miles east of Salerno. It stands in the centre of a mountainous district, of which it is the capital. It is the see of a bishop, and contains a cathedral and college, besides several churches and convents. Population, 9813.

CAMPAGNA DI ROMA, is, in the wider application of the word, an extensive plain of central Italy, almost coinciding with the ancient Latium, and, in a more restricted signification, that portion of the larger area which lies immediately round the city of Rome between the Tiber and the Anio. The circumference of the latter "might be marked," says Gregorovius, "by a series of well-known points,—Civita Vecchia, Tolfa, Ronciglione, Soracte, Tivoli, Palestrina, Albano, and Ostia;" while the former may be regarded as bounded on the N. by the Mountains of Viterbo (*Sylva Ciminia*), on the E. by the lower ranges of the Apennines, and on the S. and W. by the Tyrrhenian Sea. It extends about 84 miles in length from Civita Vecchia to Terracina, and has a breadth of 24 miles,—its area being nearly 1400 square miles. Of distinctly volcanic formation, the surface presents a very undulating appearance, broken by deep gullies and studded with extinct craters, that now form the basins of lakes, such as those of Bolsena, Vico, and Baccano. In ancient times it seems to have been a well-peopled region, and was the seat of numerous cities; but in the 3d and 4th centuries B.C. the Roman aristocracy turned the most of the district into huge estates, and thus led to the disappearance of the agricultural population. In the earlier period of the empire its condition grew worse and worse, and many parts of the plain became covered with pestilential marshes. The emperors Claudius, Nerva, and Trajan turned their attention to the amelioration of the district, and under their example and exhortation the Roman aristocracy erected numerous villas within its boundaries, and used them at least for summer residence. With the ruin of the empire and the inroad of the barbarian hordes the desolation of the Campagna was complete; but, again, in the Middle Ages, it became dotted over with the baronial castles of the rival families of Rome—the Orsini, the Colonnas, the Savelli, the Conti, and the Caetani—who ruthlessly destroyed the remains of earlier edifices to obtain materials for their own. Several of the popes, as Boniface IX., Sixtus IV., and Julius III., made unsuccessful attempts to improve the sanitary condition of the Campagna; and equally fruitless in more recent times—as far, at least, as the general purpose is concerned—have been the efforts of Popes Pius VI. and VII., and of General Miollis, the French governor of Rome. The most healthy portions of the territory are in the north and east, embracing the slopes of the Apennines which are watered by the Teverone and Saccho; and the most pestilential is the stretch between the Lepini Hills and the sea. The Pontine marshes, included in the latter division, were drained, according to the plan of Bolognini, by Pius VI.; but though they have been restored to cultivation, their insalubrity is still notorious. The soil in many parts is very fertile; and the atmosphere, which is so deadly to man, has no hurtful effect on the lower animals. In summer, indeed, the vast expanse is little better than an arid steppe; but in the winter it furnishes abundant pasture to flocks of sheep and herds of silver-grey oxen and shaggy black horses. The land is for the most part let by the proprietors to *Mercanti di Campagna*, who employ a subordinate class of factors (*fattori*) to manage their affairs on the spot. It is evident that the malaria which renders the Campagna almost uninhabitable during the summer is owing to natural causes affecting a wide area with which it is very difficult to deal, and that no merely local improvements can have any effect. The regulation of the rivers is so defective that they annually overflow a great extent of surface; the character of the soil allows the waters to gather in fetid masses, and the heat of summer turns them into noxious vapours. The attention of the Italian Government and of General Garibaldi has recently been turned towards the systematic sanitary improvement of the district, —with what results remains to be seen. The planting of the *Eucalyptus globulus* and the *Helianthus annuus* has been partially resorted to, especially in the district of Tre Fontani, and, it is reported, with some success.

Full details on the Campagna will be found in Westphal, *Die Römische Campagna*, 1829; Didier, *La Campagne de Rome*, 1842; Adolph Stahr, *Ein Winter in Rom*, 1847–50; Paolo Mantovani, *Descrizione geologica della Campagna Romana*, Turin, 1875; Dr Pietro Balestra, *L'Igiene nella Campagna e città di Roma*, 1875; Augustus Hare, *Days near Rome*, 1875. See also an article by Fr. Siebmann in *Ausland* for August 1875, and another by Fr. von Hellwald in the following number.

CAMPAN, Jeanne Louise Henriette (1752–1822), *née* Genest, was born at Paris in 1752. Carefully educated, and surrounded by the most cultivated society, at the age of fifteen she had gained so high a reputation for her accomplishments as to be appointed reader to the young princesses. At court she was a general favourite, and when she bestowed her hand upon M. Campan, son of the secretary of the royal cabinet, the king gave her an annuity of 5000 livres as dowry. She was soon after appointed first lady of the bedchamber by Marie Antoinette; and she continued to be the faithful attendant of that princess till she was forcibly separated from her at the sacking of the Tuileries, on 20th June 1792. After this event Mme. Campan, almost penniless, and thrown on her own resources by the illness of her husband, bravely determined to support herself by establishing a school at Saint-Germain. The institution prospered, and was patronized by Mme. Beauharnais, whose influence led to the appointment of Mme. Campan as superintendent of the academy founded by Napoleon at Ecouen, for the education of the daughters and sisters of members of the Legion of Honour. This post she held till it was abolished at the restoration of the Bourbons, when she retired to Mantes, where she spent the rest of her life amid the kind attentions of affectionate friends, but saddened by the loss of her only son, and by the calumnies circulated on account of her connection with the Bonapartes. She died in 1822, leaving interesting *Mémoires sur la vie privée de Marie Antoinette, suivis de souvenirs et anecdotes historiques sur les règnes de Louis XIV.–XV.* (Paris, 1823); a treatise *De l'Éducation des Femmes*; and one or two small didactic works, written in a clear and natural style.

CAMPANELLA, Tomaso (1568–1639), one of the most brilliant and unfortunate of the Italian Renaissance philosophers, was born at Stilo in Calabria in 1568. At a very early age he showed remarkable mental power; his memory was uncommonly tenacious, and before he was thirteen years of age he had mastered nearly all the Latin authors presented to him. In his fifteenth year he entered the order of the Dominicans, attracted partly by reading

the lives of Albertus Magnus and Aquinas, partly by his intense love of learning. He was placed at first in the convent at Morgentia in Abruzzo, and after completing his course of philosophy was transferred to Cosenza, there to study theology. He soon became discontented with his teachers, for he earnestly desired to read, not only the works of Aristotle, but the book of nature, which was the language of God. An accident drew his attention to the work *De Rerum Natura* of Telesius, which he read with great eagerness. He was delighted with its freedom of speech and its appeal to nature rather than to authority. His first work in philosophy, for he was already the author of numerous poems, was a defence of Telesius against the attacks of Marta, an Aristotelian. It was styled *Philosophia sensibus demonstrata*, and appeared in 1591. The freedom and boldness of his attacks upon established authority soon brought him into disfavour with the clergy. He left Naples, where he had been residing, and proceeded to Rome For seven years he led an unsettled life, wandering through Padua, Bologna, Venice and other towns, everywhere attracting attention by the brilliancy of his talents and the boldness of his teaching. Yet Campanella was strictly orthodox, held the established faith, and was an uncompromising advocate of the Pope's temporal power

He returned to Stilo in 1598. In the following year he was arrested and committed to prison. What was the immediate cause of this is not clearly known. According to the most common report the motives for his imprisonment were entirely political. He had joined himself to those who desired to free Naples from Spanish tyranny, and had excited them by his fiery eloquence and independence of spirit. His friend Naudée, however, declares that this was a complete mistake, and that the expressions used by Campanella, which were interpreted as revolutionary, had quite a different reference and signification. Whether from error or not, the unfortunate philosopher was committed to prison, and remained there for twenty-seven years, suffering much torture and misery. Yet his spirit was unbroken; he composed sonnets, and prepared a series of works, forming a complete system of philosophy, which were published at a later date. During the latter years of his long confinement he was kept in the castle of St Elmo, and was allowed considerable liberty. There seem, indeed, to have been great doubts even in the minds of those who imprisoned him whether he had done anything deserving such a punishment. Still he was looked upon as dangerous, and it was thought better to restrain his boldness. At last, in 1626, he was set at liberty For some three years he was confined in the chambers of the Inquisition, but in 1629 he was fairly free. He was well treated at Rome by the Pope, but he made enemies; and, profiting by the lessons of experience, he thought it well to avoid future danger by taking flight from Rome. He came to Paris in 1634 under the protection of the French ambassador to Italy, and was received with marked favour by Cardinal Richelieu. The last few years of his life he spent in preparing a complete edition of his works; but only the first volume appears to have been published. He died on the 26th of May 1639.

The philosophy of Campanella is in many respects interesting and important, but it has much that is fantastic, and is wanting in unity and completeness. With Telesius he agreed in rejecting the Aristotelian method of inference. According to him truth or certainty is only to be found in immediate intuition. The sciences are not to be constructed from definitions by deduction, but proceed by induction to definition, which in the natural order comes last. The syllogism is only useful for expounding; the universal rule which it involves is always a result of induction; and the particular subsumed under it is itself part of the induction. Our knowledge begins in doubt. We know neither the past nor the future; even in the present we only know things as they appear to be, not as they are. The first proposition in a theory of cognition is that I myself think; the certainty of self-consciousness is the primary truth.

With all this freedom of philosophizing Campanella preserved a completely orthodox respect for revealed religion; he aimed indeed at a system which should embrace in one comprehensive scheme religious and philosophical principles. His view of God is not far removed from that of Bruno; he lays stress upon the divine unity and omnipresence, and as he is convinced that community of action is only possible where there is identity of being, he is driven to an apparently pantheistic conclusion. God is the ultimate unit; His three manifestations may be called power, wisdom, and love. He alone has pure being; all other things created by or emanating from Him are limited, *i.e.*, have non-being. All things are of the same nature, otherwise there could be no mutual action; there is a universally diffused life and sensibility.

In his natural philosophy Campanella mainly follows Telesius, and lays down as fundamental forces heat and cold, in their concrete form, sun and earth. By these all things are formed. The soul of man is in nature corporeal, but is immortal, being endowed with a striving after happiness never attained in this life.

In practical philosophy Campanella was an extreme reformer. In his *Civitas Solis* he sketches an ideal state, in which principles of communism are fully carried out. He contends for a community of goods and wives, for state control of population, and for a universal military training. The king in his ideal state is called Hoh, *i.e.*, Metaphysics; his ministers have names meaning respectively Power, Wisdom, and Might. The whole work is cold and abstract, utterly wanting in the rich practical detail of its prototype, the *Utopia*.

A long list of Campanella's works is given by Echard, App. to Cypriano, *Vita Campanellæ*, who enumerates eighty-two, and by Campanella himself in the first vol. of his collected works. The most important were *De Sensu Rerum*, 1620; *Realis Philosophiæ Epilogisticæ Partes IV.* (containing *Civitas Solis*), 1623; *Atheismus Triumphatus*, 1631; *Philosophia Rationalis*, 1637; *Philosophia Universalis seu Metaphysica*, 1638; *De Monarchia Hispanica*, 1640, translated into English.

See on his life Cypriano, *Vita Campanellæ*, 1705, 1722; Baldacchini, *Vita et Filosofia di Tomaso Campanella*, 1840. On his philosophy, see Ritter, *Ges. d. Phil.* vol. ix., who gives a very full account; Carriere, *Phil. Weltanschauung der Reformationszeit*, 522–608; Dareste, *Th. Morus et Campanella*, 1843. Some of the works have been translated into French, *Œuvres choisies de Campanella*, par Mme. L. Collet, 1844; *Cité du soleil*, par Villegardelle, 1840.

CAMPANIA, an ancient province of Italy, separated from Latium on the N. by the Massican Hills, and from Samnium on the E. by the Apennines, and bounded on the W. by the Tyrrhenian Sea, and on the S. by Lucania. It was distinguished by its fertility, beauty, and genial climate, and by the excellence of its harbours. It consists of a plain, broken only by a low volcanic range of hills, of which the chief is Mons Gaurus, and by Mount Vesuvius. The original inhabitants of Campania were Oscans or Ausonians. The first settlers were the Greeks who founded Cumæ, and afterwards Dicæarchia, Palæpolis, and Neapolis. It seems pretty certain that the next invaders were the Etruscans, and that they founded Capua and Nola. The Etruscans in turn had to give place to the Samnites. But both these invaders were few in number; and the Campanian people continued to be of essentially Oscan race. The remains of their language are, indeed, our best specimen of Oscan. In the 4th century B.C. war broke out with the Romans, and in 340 B.C., by the battle of

Vesuvius, Campania fell into their hands. For subsequent history see ROMAN HISTORY. The Bay of Naples was one of the favourite situations for the villas of the ancient Romans; and, notwithstanding the eruption of Vesuvius in 79 A.D., which buried the cities of Herculaneum and Pompeii, Campania continued to flourish. The chief towns were Capua, Cumæ, Neapolis, Nola, Pompeii, Herculaneum, Vulturnum, Puteoli, Liternum, Teanum, Salernum, Suessa, Misenum, Surrentum, Picentia. The province was traversed by several roads—the Via Appia, the Via Latina, part of the high road from Rome to Rhegium, and a road constructed by Domitian along the coast from Sinuessa to Neapolis. Under Augustus, Campania was joined to Latium to form the First Region of Italy Its name then gradually superseded that of Latium; so that at present the district round Rome is known as the Campagna di Roma.

CAMPANI-ALIMENIS, MATTEO, an Italian mechanician and natural philosopher of the 17th century, was born at Spoleto. He held a curacy at Rome in 1661, but devoted himself principally to scientific pursuits. As an optician, he is chiefly celebrated for the manufacture of the large object-glasses with which Cassini discovered two of Saturn's satellites, and for an attempt to rectify chromatic aberration by using a triple eye-glass; and in clock-making, for his invention of the illuminated dial-plate, and that of noiseless clocks, as well as for an attempt to correct the irregularities of the pendulum which arise from variations of temperature. Campani published in 1678 a work on horology, and on the manufacture of lenses for telescopes. His younger brother Giuseppe was also an ingenious optician (indeed the attempt to correct chromatic aberration has been ascribed to him instead of to Matteo), and is, besides, noteworthy as an astronomer, especially for his discovery, by the aid of a telescope of his own construction, of the spots in Jupiter, the credit of which was, however, also claimed by Divini.

CAMPANILE, the bell tower attached to the churches and town-halls in Italy. Bells are supposed to have been first used for announcing the sacred offices by Pope Sabinian (604), the immediate successor to St Gregory; and their use by the municipalities came with the rights granted by kings and emperors to the citizens to enclose their towns with fortifications, and assemble at the sound of a great bell. It is to the Lombard architects of the north of Italy that we are indebted for the introduction and development of the campanile, which, when used in connection with a sacred building, is a feature peculiar to Christian architecture,—Christians alone making use of the bell to gather the multitude to public worship. The campanile of Italy serves the same purpose as the tower or steeple of the churches in the north and west of Europe, but differs from it in design and position with regard to the body of the church. In the north and west the tower forms an integral part of the building; it is frequently placed at the west end or at the south or north side of the nave, in which case the ground story forms a porch to the church; sometimes it is at the intersection of the nave and transepts, in which case it rises as a grand central feature round which everything else groups, as seen at Salisbury, Lincoln, Norwich, &c. In Italy the campanile is almost always detached from the church, or at most connected with it by an arcaded passage. In Italy there are (with one or two exceptions, such as San Ambrosio, Milan, and at Novara) never more than one campanile to a church, whereas in the north and west the number varies from one to seven.

The design of the campanile differs entirely from its northern type. It never has buttresses, is very tall and thin in proportion to its height, and is square on plan, occasionally round, as at Ravenna and Pisa, and in one or two cases, as at San Gottardo, Milan, octagonal. The campanile generally rises from base to summit without break; the faces are divided vertically by flat pilasters, and horizontally by string-courses, arcades, or windows. As a rule the openings increase in number with the height of the stage. Many, perhaps the finest examples, have openings at the top only.

The chief architectural defect of the square campanile is the covering. This is generally a short conical roof, either square, circular, or octagonal on plan; but its junction with the tower was never successfully managed. The campanili in the north of Italy and in Rome are nearly all built of brick. In Tuscany, as at Pisa and Siena, and further south, as at Viterbo, they are veneered with marble of various colours.

The tallest campanile is the one at Cremona; it rises to a height of 396 feet. Probably the grandest and richest is that designed by Giotto in 1334 for the cathedral at Florence. It measures 275 feet high and 45 feet square; it is entirely veneered with black, red, and white marble, and is divided into five stages, the upper three only having windows. Giotto intended to have finished it with a spire 90 feet high, but Taddio Gaddi, who succeeded Giotto as architect, thinking that the tower would not be improved by it, left it as it now exists. Some of the best examples of church campanili are to be found in Venice, Verona, Modena, Cremona, Parma, and Pisa.

The campanili belonging to the municipalities have generally a distinct character from those attached to sacred edifices; they have a smaller section on plan in proportion to the height. They want the conical roof, and are generally battlemented; some have an upper and smaller stage, wherein the bells are hung, as at Florence, Siena, Volterra, and Montepulciano. Their faces are rarely divided by pilasters; there are few windows, generally small openings only to light the staircase; and they are more frequently incorporated with the body of the building than the church campanili, often rising from the wall heads and not from the ground to great heights. The most remarkable campanili are those at Venice, Florence, Pisa, and Siena. The campanile of St Mark's at Venice stands in the great square in front of the cathedral. Its erection was commenced about the beginning of the 10th, and completed up to the belfry about the middle of the 12th century. The belfry was erected and finished by Bartolomeo Buono in 1517. From the level of the piazza to the belfry stage, it is constructed of brick; the belfry and surmounting pyramid are of marble. The total height is 323 feet, and it is 42 feet square at the base. The gallery at top is reached by an inclined plane, and there are no windows other than small openings lighting the ascent.

The leaning tower or campanile of Pisa, built by the citizens to rival that of Venice, was erected by Bonanno, and begun in the year 1174. It is circular on plan, and about 51 feet in diameter and 172 feet high. Not including the belfry it is divided vertically into seven stages, all of which, with the exception of the lowest, are decorated with an open arcade. The conical covering of the belfry was never constructed. This tower overhangs its base upwards of 13 feet, and for long it was supposed to have been built so. It is founded on wooden piles driven into boggy ground. When the tower had been carried up about 35 feet it began to settle to one side. That no such settlement was ever anticipated may be asserted from the fact that a gurgoyle or water-spout to throw off the water from the first arcade, may be observed on what is now the highest side. As the work was carried on, the levels were altered so as to keep the centre of gravity within the base. This tower was finished by an architect called William of Innspruck. The outside is entirely constructed

of white marble, and the inside of stone from Verruca. There are many campanili, notably the Garisendi and Asinelli towers at Bologna, that incline to one side,—all from the same cause as at Pisa.

The campanili of Florence and Siena are somewhat similar in design. The one at Florence is built of stone, and is about 20 feet square and about 300 feet high. That at Siena is built entirely of brick, and measures about 21 feet square and 282 feet high. Both are battlemented and have a smaller upper stage for the belfry. Several other important examples exist at Volterra, Montepulciano, Figline, Oppi, &c., &c. (R. AN.)

CAMPBELL, SIR COLIN. See CLYDE, LORD.

CAMPBELL, GEORGE (1719-1796), a theologian and Biblical critic, was born at Aberdeen on the 25th December 1719. His father, the Rev. Colin Campbell, one of the ministers of Aberdeen, was the son of George Campbell of Westhall, who claimed to belong to the Argyll branch of the family. Mr Colin Campbell died in 1728, leaving a widow and six children in somewhat straitened circumstances. George, the youngest son, was destined for the legal profession, and after attending the grammar school of Aberdeen and the arts classes at Marischal College, he was sent to Edinburgh to serve as an apprentice to a writer to the Signet. But he does not seem to have had any liking for law—at any rate he found in theology a study much more to his taste. While at Edinburgh he fell into the habit of attending the theological lectures, and this was followed, when the term of his apprenticeship expired, by his enrolment as a regular student in the Aberdeen divinity hall. After a distinguished career he was, in 1746, licensed to preach by the Presbytery of Aberdeen; but his first attempt to obtain a charge—that of Fordoun in Kincardineshire—was unsuccessful. In 1748, however, he was ordained minister of Banchory Ternan, a parish on the Dee, some twenty miles from Aberdeen. Here he spent the next nine years, labouring with much success as a country minister, and planning two at least of the works by which he was afterwards to make himself known. In 1757 he left Banchory Ternan to become one of the ministers of Aberdeen. That city was at the time the centre of no inconsiderable intellectual activity. Reid was professor of philosophy at King's College; John Gregory, Reid's predecessor, held the chair of medicine; Alexander Gerard was professor of divinity at Marischal College; and in 1760 Beattie became professor of moral philosophy in the same college. These men, with others of less note, formed themselves in 1758 into a society for the discussion of questions in philosophy. Reid was its first secretary, and Campbell one of its founders. It lasted till about 1773, and during this period not a few papers were read, particularly those by Reid and Campbell, which were afterwards extended in the form of published treatises.

Meanwhile Campbell was, in 1759, made principal of Marischal College, an appointment due rather to the high estimation in which he was held by those who knew him, and perhaps also to his family influence with the duke of Argyll, than to any published evidence he had given of his fitness for the post. But this evidence, if it was required, was soon forthcoming. In 1763 he published his celebrated *Dissertation on Miracles*, a work that originated in a sermon preached two years previously before the Synod of Aberdeen. In it he seeks to show, in opposition to Hume, that miracles are capable of proof by testimony and that the miracles of Christianity are sufficiently attested. Hume derived our belief in testimony equally with our belief in the laws of nature from experience; he held that where the laws of nature, being a uniform experience, contradict testimony, the latter must give way; and he further held that in the case of miracles the laws of nature do actually contradict the testimony in favour of miracles, *i.e.*, miracles are incapable of proof. In reply Campbell asserts—(1) that testimony is not derived from experience, but "has a natural and original influence on belief antecedent to experience." As, however, he admits that experience is, if not the source, at least the measure, of testimony, he virtually grants all that Hume desires, and leaves the question where it was. But (2) he urges, and with more success, that testimony can prove a miracle. There is no contradiction, he argues, as Hume said there was, between what we know by testimony and the evidence upon which a law of nature is based; they are of a different description indeed, but we can without inconsistency believe that both are true. He also dwells at considerable length upon the ambiguity of the word "experience" as it is used by Hume, and devotes the rest of the work to a discussion of the actual evidence for the miracles of Christianity. The *Dissertation* is not a complete treatise upon miracles, and does not approach the subject from points of view it would be regarded from now, but with all deductions it was and still is a valuable contribution to theological literature.

In 1771 Campbell was elected professor of theology at Marischal College, and in consequence he resigned his city charge, although he still preached as minister of Greyfriars, a duty then attached to the chair. His next work was not a theological one. During his early ministerial life at Banchory Ternan he planned and began the composition of a work on rhetoric. The results of his labours were partly communicated to the Aberdeen Philosophical Society, for most of the papers he read there were on "Eloquence" and cognate subjects; but it was not until 1776 that his *Philosophy of Rhetoric* appeared,—a work that at once took a high place among books on the subject, which it can hardly be said even now to have lost. The most interesting portion is perhaps that which treats of evidence; certainly the least satisfactory is that on the syllogism. In 1778 his last and in some respects his greatest work appeared, *A New Translation of the Gospels*. The translation is a good one, but it is the critical and explanatory notes which accompany it that give the book its high value. Several of his sermons were published, notably one in 1777 *On the Success of the first publishers of the Gospel, considered as a proof of its truth*. It was preached before the Society for Propagating Christian Knowledge, and is one of the happiest specimens of his style and method of argument.

Campbell, who had never enjoyed robust health, was in 1795 compelled by increasing weakness to resign the offices he held in Marischal College, and on his retirement he received a pension of £300 from the king. He did not long enjoy the royal bounty, for he died on the 31st of March 1796 of a stroke of palsy. Principal Campbell had married Miss Grace Farquharson, daughter of Mr Farquharson of Whitehouse. They had no children. In church politics he belonged to the moderate side, but his independence of judgment and strength of conviction were too great to permit him to be confined by the trammels of party. It is as a theologian and as a scholar, the acutest and most cultivated that the Church of Scotland has produced, that he will be best remembered.

His *Lectures on Ecclesiastical History* and some smaller writings were published after his death; and there is a uniform edition of his works in six vols. 8vo. A short account of his life, by the Rev. Mr Keith, is prefixed to his *Lectures on Church History*.

CAMPBELL, JOHN, LL.D. (1708-1775), a miscellaneous author, was born at Edinburgh, March 8, 1708. Being designed for the legal profession, he was sent to Windsor, and apprenticed to an attorney; but his tastes soon led him to abandon the study of law, and to devote himself entirely to literature. In 1736 he published

the *Military History of Prince Eugene and the Duke of Marlborough*, and soon after contributed several important articles to the *Ancient Universal History*. In 1742 and 1744 appeared the *Lives of the British Admirals*, in 4 vols., a popular work which has been continued by other authors. Besides contributing to the *Biographia Britannica* and Dodsley's *Preceptor*, he published a work on *The Present State of Europe*, consisting of a series of papers which had appeared in the *Museum*. He also wrote the histories of the Portuguese, Dutch, Spanish, French, Swedish, Danish, and Ostend settlements in the East Indies, and the histories of Spain, Portugal, Algarve, Navarre, and France, from the time of Clovis till 1656, for the *Modern Universal History*. At the request of Lord Bute, he published a vindication of the Peace of Paris concluded in 1763, embodying in it a descriptive and historical account of the New Sugar Islands in the West Indies. By the king he was appointed agent for the provinces of Georgia in 1755. His last and most elaborate work, *Political Survey of Britain*, 2 vols. 4to, was published in 1744, and greatly increased the author's reputation. Campbell died December 28, 1775. He received the honorary degree of LL.D. from the University of Glasgow in 1745.

CAMPBELL, Thomas (1777–1844). This distinguished poet was a cadet of the respectable family of Campbell of Kirnan, in Argyllshire. Owing to the straitened circumstances of his father, who had settled in Glasgow and been unfortunate in business, young Campbell was obliged, while attending college, to have recourse to private teaching as a tutor. Notwithstanding the amount of additional labour thus entailed, he made rapid progress in his studies, and attained considerable distinction at the university over which it was his fortune, in after years, to preside. He very early gave proofs of his aptitude for literary composition, especially in the department of poetry; and so strong was his addiction to these pursuits, that he could not bring himself seriously to adopt the choice of a profession. From private tuition, which is at best an irksome drudgery, he recoiled after a short trial. Neither law, physic, nor divinity had any attractions for him; nor is it probable that he ever would have risen to eminence in a regular profession, owing to a constitutional sensitiveness almost morbid, and a want of resolute energy. We are told by his friend and biographer Dr Beattie that "the imaginative faculty had been so unremittingly cultivated that circumstances, trifling in themselves, had acquired undue influence over his mind, and been rendered formidable by an exaggeration of which he was at the moment unconscious. Hence various difficulties, which industry might have overcome, assumed to his eye the appearance of insurmountable obstacles. Without resolution to persevere, or philosophy to submit to the force of necessity, he drew from everything around him, with morbid ingenuity, some melancholy presage of the future. He was dissatisfied with himself, chilled by the world's neglect, and greatly hurt by the apathy of friends who had extolled his merits, but left him to pine in obscurity." Campbell was not a man who could have successfully struggled with the world. Fortunately for him, his genius was such as to ensure an early recognition.

We find him at the age of twenty in Edinburgh, attending lectures at the university, soliciting employment from the booksellers, and not unknown to a circle of young men then resident in the Scottish metropolis, whose names have become historical. Among those were Walter Scott, Henry Brougham, Francis Jeffrey, Dr Thomas Brown, John Leyden, and James Grahame, the author of the *Sabbath*. He also became acquainted with Dr Robert Anderson, editor of a collection of the British poets, a man of extreme enthusiasm and kindliness of disposition, who early appreciated the remarkable powers of Campbell, and encouraged him to proceed in his literary career. In 1799 his poem, *The Pleasures of Hope*, was published.

Probably there is no parallel instance of literary success so instantaneously achieved by a first effort; nor was that owing to novelty of design on the part of the author, or the caprice of the public. For considerably more than half a century the poem has maintained, nay, increased its popularity. During that time the public has adopted and abandoned many favourites—names once famous and in every mouth have gradually become forgotten and unregarded—poetical works of greater pretension, which were once considered as masterpieces of genius and inspiration, have fallen into neglect; but this poem by the boy Campbell remains a universal favourite. It is not much to say that it is, without any exception, the finest didactic poem in the English language. Even those who are not admirers of didactic poetry are forced to admit its charm; and the uttermost objection that criticism can make appears to be a certain vagueness, which, after all, is inseparable from the nature of the subject and the necessary plan of the composition. The delicacy of the thoughts, the beauty of the imagery, the occasional power of pathos, the extraordinary felicity of the language, and the wonderful harmony of the versification, distinguish the *Pleasures of Hope* from any poem which has been written before or since, and entitle it to a very high place as an original work of genius. It is as original and characteristic of its author as is the *Deserted Village* of Goldsmith, with which it has been frequently, but surely improperly compared. Goldsmith's poem affects us by its simplicity and truth. Campbell's, it must be owned, is much more florid and ornamented; but how exquisite is the taste of the ornament!

The literary and the private histories of an author are inseparable. In order to comprehend the one we must have recourse to the other. The first success of Campbell brought him fame, but not fortune. He had disposed of the copyright of the *Pleasures of Hope*, by his original bargain with the publishers, for a sum certainly moderate, which, however, probably exceeded his expectations at the time. He was, moreover, very kindly treated, for he received a considerable unstipulated allowance for each new edition, which circumstance ought to have deterred him from uttering certain diatribes against "the trade," in which he was afterwards rather prone to indulge. The fact is that he did not know how to make use of his success. Instead of availing himself of the reputation which he had so worthily and decisively won, and applying himself to a new effort, he went abroad without any determinate aim; was perfectly wretched on the Continent, where he had no friends, and was sorely embarrassed for want of means; and began to write fugitive poetry for the London journals. On his return to Britain he had ample opportunity of bettering his condition. With a name such as his, a moderate amount of exertion would have secured him not only a competence but comparative affluence; but indolence, perhaps the result of timidity, had grown upon him. Campbell never could adapt himself even to the profession of literature, which, precarious though it be, is not without its prizes. In that profession, as in all others, the requisites for success are steadiness, punctuality, and perseverance; but Campbell possessed none of them. The publishers were ready, and offered to give him lucrative employment, nor was he at all backward in accepting their offers; but when the period for performance arrived he had literally done nothing. In extraordinary contrast to him stands Scott, who seemed simply to will in order to conceive and execute. Campbell had many bright conceptions, but he could not apply himself to the work. Of course he lost repute with the men who alone can intervene between an

author and the public, and "the fathers of the Row" became chary of offering him engagements. Some idea of the extent of his habitual indolence may be formed from the fact, that the publication of his *Specimens of the British Poets* did not take place until thirteen years after the work was undertaken!

In the meantime Campbell married; and his prospects were of the darkest, when, in 1805, he received a Government pension of £200. He was then in great distress, and even that aid, material as it was, failed to extricate him. It was probably fortunate for his fame that such was the case, for in 1809 he published his poem of *Gertrude of Wyoming*, to which were attached the most celebrated of his grand and powerful lyrics.

Among Campbell's lengthier poems *Gertrude of Wyoming* must hold the second place. He designed it for a poem of action, but he has failed to give it that interest and vivacity which a poem of action requires. There is in it too decided a predominance of the sentimental vein, and an extreme degree of elaboration, which, in poetry as in painting, is hurtful to the general effect. There is great truth in the following criticism, which occurs in a letter from Jeffrey to the author:—"Your timidity or fastidiousness, or some other knavish quality, will not let you give your conceptions glowing, and bold, and powerful, as they present themselves; but you must chasten, and refine, and soften them, forsooth, till half their nature and grandeur is chiselled away from them. Believe me, the world will never know how truly you are a great and original poet till you venture to cast before it some of the rough pearls of your fancy." In spite of these defects, *Gertrude* was considered at the time as a work in every way worthy of the poet's previous reputation; and it will ever be admired by that numerous class of readers who are more fascinated by the beauties of expression than by high inventive power and vigorous execution.

The soundness of the above criticism, proceeding from an eminent literary authority whose whole leanings were rather towards than against fastidiousness in composition, is demonstrated by the universal admiration accorded to Campbell's lyrical pieces. One or two of these, in particular *Lochiel's Warning* and *Hohenlinden*, are to be referred to an earlier period than the composition of *Gertrude*; but there are others of a later date which show how much power remained in the man when he chose to exert it freely. There are few lyrics in the English language to be placed in comparison with the *Mariners of England* or *The Battle of the Baltic*; and his exquisite poem of *O'Connor's Child*, which has not unaptly been termed the diamond of his casket of gems, is greatly superior in pathos and passion to his more elaborate compositions. All these, and others scarcely inferior to them, seem to have been struck off at a heat, and to have escaped that chiselling process to which Jeffrey so pointedly referred.

Campbell was now settled at Sydenham in England, and his circumstances were materially improved. His home was a happy one; the society in which he moved was of the most refined and intellectual character; and he enjoyed the personal friendship of many of his distinguished contemporaries. Ample leisure was afforded him to carry into effect any of the cherished schemes of his literary ambition; but his indolence and inherent want of resolution again interfered. His most noteworthy exertion for years appears to have been the preparation of a short course of lectures on poetry, which he delivered with great *éclat* at the Royal Institution in London and elsewhere. It appears that at one time it was proposed by his friends, and especially by Sir Walter Scott, that he should become a candidate for the occupancy of a literary chair in the University of Edinburgh; but he shrank from the idea of undertaking so serious a labour as is involved in the preparation of a thorough academical course. In 1820 he accepted the editorship of the *New Monthly Magazine*, and acted in that capacity for a considerable period, until he resigned it to take charge of the *Metropolitan*. His connection with periodical literature may have been advantageous in a pecuniary point of view, but did not tend materially to enhance his reputation. His was not the pen of the ready writer; and it must ever be regretted that he was induced to bestow so much attention upon merely ephemeral literature, to the sacrifice of the nobler aims which were expected from his acknowledged genius. In 1824 he published his *Theodric*, a poem which, in spite of some fine passages, was generally considered as a failure. With *Theodric* his poetical career may be said to have closed. At times he put forth short poems of various degrees of merit, but none of them were equal to the grand lyrics already treasured in the memory of his countrymen. It seemed as if a large portion of the old virtue had departed from him; and his last published poem, the *Pilgrim of Glencoe*, showed hardly any marks of his former accomplishment and power.

In fact it appeared that the rich mine of poetry had been worked out. Without actually adopting that conclusion, we may observe that Campbell had latterly occupied himself most zealously with matters which were apart from his earlier pursuits. In the first place, he took an active share in the Institution of the London University, and it was mainly through his exertions that it was saved from becoming a mere sectarian college. Shortly afterwards, in 1826, he was elected Lord Rector of the University of Glasgow, an event which he considered as the crowning honour of his life, and which certainly was a mark of distinction of which any man might have been proud. He did not accept the office as a mere sinecure, but applied himself to discharge the actual duties (which, through the negligence of former rectors, had been allowed to fall into abeyance) with a zeal and energy which made entire conquest of the hearts of his youthful constituents. In 1831, the year in which the gallant struggle of the Poles for their independence was terminated by entire defeat, Campbell, who in his earliest poem had referred in such beautiful language to the shameful partition of Poland, more than revived his youthful enthusiasm for her cause. He had watched with an anxiety almost bordering on fanaticism the progress of the patriotic movement; and the news of the capture of Warsaw by the Russians affected him as if it had been the deepest of personal calamities. "His heart," says his biographer, "was in the subject of Poland; he could neither write nor speak upon any other with common patience; and if a word was dropt in company that did not harmonize with his feelings, he was very apt to consider it as a personal offence." In one of his own letters he says, "I know that my zeal for Poland has put me half mad." And again, "It is still all that I can do to support a tolerable cheerfulness before these kind hospitable people, for Poland preys on my heart night and day. It is sometimes a relief to me to weep in secret, and I do weep long and bitterly." Nor did he show his sympathy by words alone, but by resolute and continued action. He was the founder of the association in London of the Friends of Poland, which not only served to maintain the strong interest felt by the British people for the Polish cause, but was the means of providing assistance and giving employment to large numbers of the unfortunate exiles who were driven to seek refuge in this country. Never, till his dying day, did he relax his exertions in their behalf; and many an unhappy wanderer, who, but for unexpected aid, might have perished in the streets of a foreign city, had reason to bless the name of Thomas Campbell.

The remainder of his life presents few features of interest. Domestic calamity had overtaken him. His wife, whom he loved affectionately, had been taken from him—of his two sons, one died in infancy, and the other was afflicted by an incurable malady. His own health became impaired. He gradually withdrew from public life, and died at Boulogne on 15th June 1844, at the age of sixty-seven. His last hours were soothed by the affectionate care of his relatives and friends; nor did his countrymen forget the poet in his death, for his remains were solemnly interred in Westminster Abbey, with the honours of a public funeral.

Few poets of reputation, whose span has been extended nearly to the threescore and ten allotted years, have written so little as Campbell: at the same time it must be confessed that there are fewer still whose works are likely to be prized by posterity in the like proportion with his. If we throw out of consideration altogether *Theodric*,—though some might demur to such an excision,—if we overlook the *Pilgrim of Glencoe*, and weed from his lyrical garden such plants as have little charm either from their colour or their fragrance, there will still remain a mass of poetry familiar to the ear and the heart, such as hardly any other writer of this century has been able to produce. We may regret that Campbell was not more diligent in the cultivation of his poetical genius, that he did not apply himself more sedulously in his earlier years to some serious effort, and that he allowed other pursuits and designs to interfere with his peculiar calling. But who can venture to say what success might have attended his efforts had he acted otherwise than he did? We blame the poet for apparent indolence, not reflecting that inspiration is not to be commanded at will. It is not only possible but easy for the man who is practised in versification to write a certain given number of lines within a certain specified time; but genuine poetry never was and never will be the product of Egyptian taskwork. It cannot be produced to order—it must be spontaneous; and its quality must depend entirely upon the mood of mind under which it is composed. The greater part of the poetry or rather the verse of Southey, a considerable portion of that of Scott, and a vast deal of that of Wordsworth, was not conceived or written under the poetic impulse. On such occasions these celebrated men were writing verse, as they might have written prose, without enthusiasm or anything like the feeling of passion; and although their ordinary thoughts were far higher, bolder, and more subtle than those of the million, they still were not attempting to rise beyond their ordinary intellectual level. One can see at a glance when they were inspired, and when they were merely versifying. Of the poets who adorned the first half of the present century, Coleridge and Campbell were conspicuous for their abstinence in writing except under the influence of real emotion. Of the former it may be said that he has hardly penned a line of mere mechanical verse; the latter did not do so until his inspiration seemed to have abandoned him. Undoubtedly, however,—to have recourse to a hackneyed, though by no means an unmeaning phrase,—it is the duty of the poet to woo the muse, not to wait for her courtship. He must seek for the waters of Castaly, not tarry till they are conveyed to him; and it is in this respect probably that Campbell principally erred. He did not sufficiently endeavour to awake his genius; he was too much a dreamer, and may at times have lost his opportunity from the sheer weight of indolence. And yet, considering the value of the legacy he has left, we have no reason to complain. Critics may dispute regarding the comparative merits of his longer works; and, as they incline towards didactic or narrative poetry, may prefer the one composition to the other. Both are entitled to high praise and honour, but it is on his lyrics that the future reputation of Campbell must principally rest. They have taken their place, never to be disturbed, in the popular heart; and, until the language in which they are written perishes, they are certain to endure. (W. E. A.)

CAMPBELL, JOHN, BARON (1779–1861), the second son of the Rev. George Campbell, D.D., by Magdalene, the only daughter of John Hallyburton, Esq. of Fodderance, was born at Cupar, Fife, on 17th September 1779. His father was for fifty years the parish minister of Cupar. For a few years young Campbell studied at the United College, St Andrews, where he met Thomas Chalmers. In 1800 he was entered as a student at Lincoln's Inn, and became a pupil of the well-known special pleader Mr Warren, the master of Lyndhurst, Denman, and Cottenham. A few days after his entrance, as he records in his *Lives of the Chancellors*, he saw and heard Lord Thurlow speak in the House of Lords. After a short connection with the *Morning Chronicle* he was called to the bar in 1806, and at once began to report cases decided at *Nisi Prius* (*i.e.*, on Jury Trial), in the courts of King's Bench and Common Pleas, and on the home circuit. Of these *Reports* he published altogether four volumes, with learned notes; they extend from Michaelmas 1807 to Hilary 1816. Campbell also devoted himself a good deal to criminal business, but in spite of his unceasing industry he failed to attract much attention behind the bar; briefs came in slowly, and it was not till 1827 that he obtained a silk gown and found himself in that "front rank" who are permitted to have political aspirations. When George IV. died (26th June 1830) and Parliament was dissolved (24th July), Campbell, like all the new Whig men of the day, resolved to enter Lord Grey's Parliament. With the help of his relative Major Scarlett he contested the borough of Stafford, which he represented in 1830 and 1831. In the House he showed an extraordinary, sometimes an excessive zeal for public business, speaking on all subjects with practical sense, but on none with eloquence or spirit. His main object, however, like that of Brougham, was the amelioration of the law, more by the abolition of cumbrous technicalities than by the assertion of new and striking principles. Thus his name is associated with the Fines and Recoveries Abolition Act (3 and 4 Will. IV. c. 74); the Law of Descent Act (3 and 4 Will. IV. c. 106); the Law of Dower Act (3 and 4 Will. IV. c. 105); the Statute of Limitations (3 and 4 Will. IV. c. 27); the Execution of Wills of Real or Personal Property Act (1 Vict. c. 26); one of the Copyhold Tenure Acts (4 and 5 Vict. c. 25); and the Imprisonment for Debt Act (1 and 2 Vict. c. 110). All these measures were important and were carefully drawn; but their merits cannot be explained in a biographical notice. The second was called for by the preference which the common law gave to a distant collateral over the brother of the half-blood of the first purchaser; the fourth conferred an indefeasible title on adverse possession for twenty years (a term shortened by Lord Cairns in 1875 to twelve years); the fifth reduced the number of witnesses required by law to attest wills, and removed the vexatious distinction which existed in this respect between freeholds and copyholds; the last freed an innocent debtor from imprisonment only before final judgment (or on what was termed *mesne process*), but the principle stated by Campbell that only fraudulent debtors should be imprisoned was ultimately given effect to for England and Wales in 1869.[1] In one of his most cherished objects, however, which formed the theme of his maiden speech in Parliament, Campbell was doomed to disappoint-

[1] Two of his later Acts, allowing the defendant in an action for libel to prove *veritas*, and giving a right of action to the representatives of persons killed through negligence, also deserve mention.

ment. This was the establishment of a general Register of Deeds or Titles to Land for England and Wales, which would diminish the number of unmarketable and unsafe titles, and thus simplify and cheapen the transfer of land. As head of the Real Property Commission of 1827, he had ample opportunity of observing the evils caused by the absurd system of outstanding terms,[1] and he was able to quote the example of most European countries, where compulsory publication had been found neither to hurt commercial credit nor to wound family pride. The measure of 1830 was defeated by the country attorneys, led by Sir Chas. Wetherell, but the principle has rapidly gained ground and has been partially embodied in the Land Transfer Bills of subsequent reformers. Campbell's most important appearance as member for Stafford was in defence of Lord John Russell's first Reform Bill (1831). In a temperate and learned speech, based on Fox's declaration against constitution-mongering, he supported both the enfranchising and the disfranchising clauses, and easily disposed of the cries of "corporation robbery," "nabob representation," "opening for young men of talent," &c. The following year (1832) found Campbell solicitor-general, a knight, and member for Dudley, which he represented till 1834. In that year he became attorney-general and was returned by Edinburgh, for which he sat till 1841.[2]

His political creed declared upon the hustings there was that of a moderate Whig. He maintained the connection of church and state, opposed triennial parliaments and the ballot, and railed against the dictatorship of the great duke (see *Speech* at Edinburgh, 3d January 1835, 8vo, London, 1835). Although in his relations with his constituents in both England and Scotland there was traceable an unpleasant spirit of accommodation and cajolery, in Parliament his position, both political and religious, was always well defined and independent. There he continued to lend the most effective help to the Liberal party. His speech in 1835 in support of the motion for inquiry into the Irish Church Temporalities with a view to their partial appropriation for national purposes (for disestablishment was not then dreamed of as possible) contains much terse argument, and no doubt contributed to the fall of Peel and the formation of the Melbourne cabinet. The next year Campbell had a fierce encounter with Lord Stanley in the debate which followed the motion of Mr Spring Rice on the repair and maintenance of parochial churches and chapels. The legal point in the dispute (which Campbell afterwards made the subject of a separate pamphlet) was whether the churchwardens of the parish, in the absence of the vestry, had any means of enforcing a rate except the antiquated interdict or ecclesiastical censure. It was not on legal technicalities, however, but on the broad principle of religious equality, that Campbell supported the abolition of Church Rates, in which he included the Edinburgh Annuity-Tax. In the same year he spoke for Lord Melbourne in the action (thought by some to be a political conspiracy[3]) which was brought by Mr Norton against the Whig premier for criminal conversation with the beautiful and accomplished grand-daughter of Sheridan. At this time also he exerted himself for the reform of justice in the ecclesiastical courts, for the uniformity of the law of marriage (which he held should be a purely civil contract), and for giving prisoners charged with felony the benefit of counsel. His defence of the *Times* newspaper, which had accused Sir John Conroy, equerry to the duchess of Kent, of misappropriation of money (1838), is chiefly remarkable for the confession—"I despair of any definition of libel which shall exclude no publications which ought to be suppressed, and include none which ought to be permitted." His own definition of blasphemous libel was enforced in the prosecution which, as attorney-general, he raised against the bookseller Hetherington, and which he justified on the singular ground that "the vast bulk of the population believe that morality depends entirely on revelation; and if a doubt could be raised among them that the Ten Commandments were given by God from Mount Sinai, men would think they were at liberty to steal, and women would consider themselves absolved from the restraints of chastity." But his most distinguished effort at the bar was undoubtedly the speech for the House of Commons in the famous case of Stockdale *v.* Hansard. The Commons had ordered to be printed, among other papers, a Report of the Inspectors of Prisons on Newgate, which stated that an obscene book, published by Stockdale, was given to the prisoners to read. Stockdale sued the Commons' publisher, and was met by the plea of parliamentary privilege, to which, however, the judges did not give effect, on the ground that they were entitled to define the privileges of the Commons, and that publication of papers was not essential to the functions of Parliament. The matter was settled by the Act 3 Vict. c. 9.

In 1840 Campbell conducted the prosecution against John Frost, one of the three Chartist leaders who attacked the town of Newport, all of whom were found guilty of high treason. We may also mention, as matter of historical interest, the case before the High Steward and the House of Lords which arose out of the duel fought on Wimbledon Common between the earl of Cardigan and Captain Harvey Tuckett. The law of course was clear that the "punctilio which swordsmen falsely do call honour" was no excuse for wilful murder. To the astonishment of everybody Lord Cardigan escaped from a capital charge of felony because the full name of his antagonist (Harvey Garnett Phipps Tuckett) was not legally proved. It is difficult to suppose that such a blunder was not preconcerted. Campbell himself made the extraordinary declaration that to engage in a duel which could not be declined without infamy (*i.e.*, social disgrace) was "an act free from moral turpitude," although the law properly held it to be wilful murder. Next year, as the Melbourne administration was near its close, Plunkett, the venerable chancellor of Ireland, was forced by discreditable pressure to resign, and the Whig attorney-general, who had never practised in Equity, became chancellor of Ireland, and was raised to the peerage with the title of Baron Campbell of St Andrews, in the county of Fife. His wife, Mary Elizabeth Campbell, the eldest daughter of the first Baron Abinger by one of the Campbells of Kilmorey, Argyllshire, whom he had married in 1821, had in 1836 been created Baroness Stratheden. The post of chancellor Campbell held for only sixteen days, and then resigned it to his successor Sir Edward Sugden (Lord St Leonards). It was during the period 1841–49, when he had no legal duty, except the self-imposed one of occasionally hearing Scotch appeals in the House of Lords, that the unlucky dream of literary fame troubled Lord Campbell's leisure.[4] By two days' court work in Dublin

[1] A terminable estate in land, vested or continued in trustees, for convenience in giving security without exhibiting a title to the complete estate.

[2] If we may trust the scandalous chronicle of Greville, Campbell got this post on condition that he should not expect the ordinary promotion to the bench, a condition which he immediately violated by claiming the vice-chancellorship on the death of Sir John Leach. Pepys (Lord Cottenham) and Bickersteth (Lord Langdale) were both promoted to the bench in preference to Campbell.

[3] "There can be no doubt that old Wynton was at the bottom of it all, and persuaded Lord Grantley to urge it on for mere political purposes."—Greville, iii. 351.

[4] In 1842 he published the *Speeches of Lord Campbell at the Bar and in the House of Commons, with an Address to the Irish Bar as Lord Chancellor of Ireland.* (Edin., Black.)

he had received a pension of £4000 per annum from an ungrateful country, and he suddenly remembered what Lords Coke and Bacon had said about the debt due from every successful lawyer.

Following in the path struck out by Miss Strickland in her *Lives of the Queens of England*, and by Lord Brougham's *Lives of Eminent Statesmen*, he at last produced, in 1849, *The Lives of the Lord Chancellors and Keepers of the Great Seal of England, from the earliest times till the reign of King George IV.*, 7 vols. 8vo. The conception of this work is magnificent; its execution wretched. Intended to evolve a history of jurisprudence from the truthful portraits of England's greatest lawyers, it merely exhibits the ill-digested results of desultory learning, without a trace of scientific symmetry or literary taste, without a spark of that divine imaginative sympathy which alone can give flesh and spirit to the dead bones of the past, and without which the present becomes an unintelligible maze of mean and selfish ideas. A charming style, a vivid fancy, exhaustive research, were not to be expected from a hard-worked barrister; but he must certainly be held responsible for the frequent plagiarisms, the still more frequent inaccuracies of detail, the colossal vanity which obtrudes on almost every page, the hasty insinuations against the memory of the great departed who were to him as giants, and the petty sneers which he condescends to print against his own contemporaries, with whom he was living from day to day on terms of apparently sincere friendship. These faults are not so glaring in the lives of such men as Somers and Hardwicke, whom distance in time makes safe from personal jealousy; they are painfully apparent in the lives of Eldon, Lyndhurst, and Brougham, and they have been pointed out by the biographers of Eldon and by Lord St Leonards.[1] And yet the book is an invaluable repertory of facts, and must endure until it is superseded by something better. It was followed by the *Lives of the Chief Justices of England, from the Norman Conquest till the death of Lord Mansfield*, 8vo, 2 vols., a book of similar construction but inferior merit.

It must not be supposed that during this period the literary lawyer was silent in the House of Lords. He spoke frequently. The 3d volume of the *Protests of the Lords*, lately edited by Mr Thorold Rogers, contains no less than ten protests by Campbell, entered in the years 1842–45. He protests against Peel's Income Tax Bill of 1842; against the Aberdeen Act (6 and 7 Vict. c. 61) as conferring undue power on church courts; against the perpetuation of diocesan courts for probate and administration; against Lord Stanley's absurd bill providing compensation for the destruction of fences to dispossessed Irish tenants; and against the Parliamentary Proceedings Bill, which proposed that all bills, except money bills, having reached a certain stage, or having passed one House, should be continued to next session. The last he opposed because the proper remedy lay in resolutions and orders of the House. He protests in favour of Lord Monteagle's (Mr Spring Rice) motion for inquiry into the sliding scale of corn duties under 5 Vict. c. 14; of Lord Normanby's motion on the Queen's speech in 1834, for inquiry into the state of Ireland (then wholly under military occupation); of Lord Radnor's bill to define the constitutional powers of the home secretary, when Sir James Graham opened Mazzini's letters. In 1844 he records a solitary protest against the judgment of the House of Lords in Reg. *v.* Millis, which affirmed that a man regularly married according to the rites of the Irish Presbyterian Church, and afterwards regularly married to another woman by an Episcopally ordained clergyman, could not be convicted of bigamy, because the English law required for the validity of a marriage that it should be performed by an ordained priest.

On the resignation of Lord Denman in 1850, Campbell was appointed Chief Justice of the Queen's Bench. For this post he was well fitted by his knowledge of common law, his habitual attention to the pleadings in court, and his power of clear statement. On the other hand, at *Nisi Prius* and on the criminal circuit, he was accused of frequently attempting unduly to influence juries in their estimate of the credibility of evidence. It is also certain that he liked to excite applause in the galleries by some platitude about the "glorious Revolution" or the "Protestant succession."[2] He assisted in the reforms of special pleading at Westminster, and had a recognized place with Brougham and Lyndhurst in legal discussions in the House of Lords. But he had neither the generous temperament nor the breadth of view which is required in the composition of even a mediocre statesman. In 1859 he was made Lord Chancellor of Great Britain, probably on the understanding that Bethell should succeed as soon as he could be spared from the House of Commons. His short tenure of this office calls for no remark. In the same year he published in the form of a letter to Mr Payne Collier an amusing and extremely inconclusive essay on Shakespeare's legal acquirements. One passage will show the conjectural process which runs through the book: "If Shakespeare was really articled to a Stratford attorney, in all probability, *during the five years of his clerkship, he* visited London several times on his master's business, and he may then have been introduced to the green-room at Blackfriars by one of his countrymen connected with that theatre." The only positive piece of evidence produced is the passage from Thomas Nash's "Epistle to the Gentlemen of the Two Universities," prefixed to Greene's *Arcadia*, 1859, in which he upbraids somebody (not known to be Shakespeare) with having left the "trade of Noverint" and busied himself with "whole Hamlets" and "handfuls of tragical speeches." The knowledge of law shown in the plays is very much what a universal observer must have picked up. Lawyers always underestimate the legal knowledge of an intelligent layman. Campbell died on the 23d June 1861. It has been well said of him in explanation of his success, that he lived eighty years and preserved his digestion unimpaired. He had a hard head, a splendid constitution, tireless industry, a generally judicious temper. He was a learned, though not a scientific lawyer, a faithful political adherent, thoroughly honest as a judge, dutiful and happy as a husband. But there was nothing admirable or heroic in his nature. On no great subject did his principles rise above the commonplace of party, nor had he the magnanimity which excuses rather than aggravates the faults of others. His life is the triumph of steady determination unaided by a single brilliant or attractive quality. (W. C. S.)

CAMPBELTOWN, a royal burgh and seaport of Scotland, in Argyllshire, situated on an indentation of the coast, near the southern extremity of the peninsula of Kintyre, in 55° 25' N. lat. and 5° 36' W. long. Its principal buildings are the churches (one of which stands on the site of the castle of the Macdonalds), the town house, the jail, and the athenæum. The staple industry is the manufacture of whisky. There are in the town, or in

[1] It was of this book that Sir Charles Wetherell said, referring to its author, "and then there is my noble and biographical friend who has added a new terror to death." See *Misrepresentations in Campbell's "Lives of Lyndhurst and Brougham" corrected by St Leonards*, London, 1869.

[2] This applies particularly to his conduct of the case of [illegible] Dr Newman for libel contained in the *Lectures on the [illegible] of Protestantism*. See special *Report* by W. F. [illegible]

its immediate vicinity, upwards of twenty distilleries, which produce a spirit that is in high estimation. Many of the inhabitants are also engaged in the fisheries and the coasting trade. A good supply of water is furnished, from a distance of a mile and a half, by the works opened in 1866. The harbour, which is formed by the inlet of the sea called Campbeltown Loch, has been improved by the extension of the pier to a distance of 250 feet. The whole bay measures about 2 miles in length by 1 in breadth, and has from 6 to 15 fathoms water. The registered vessels belonging to the port on the 31st of December 1874 were 41 sailing vessels of 2590 tons and 2 steamships of 284. During the same year there entered 806 British and 18 foreign vessels, with a tonnage of 61,838 and 2353 respectively. Campbeltown unites with Ayr, Inveraray, Irvine, and Oban in sending one member to parliament. The population of the parliamentary burgh in 1871 was 4593, while that of the parish amounted to 8580. Campbeltown is supposed to be a place of considerable antiquity, though no memorial of this exists except a finely-sculptured stone cross, which now stands on a pedestal in the market-place, and is popularly assigned to the 12th century. Prior to 1700 the place was a mere fishing village, but it was then erected into a royal burgh through the interest of the Argyll family, from whom it derived its name.

CAMPE, Joachim Heinrich (1746–1818), a German educationist, was born at Deensen in Brunswick in 1746. He studied theology at the university of Halle, and after acting for some time as chaplain at Potsdam, he accepted a post as director of studies in the Philanthropin at Dessau. He soon after set up an educational establishment of his own at Trittow, near Hamburg, which he was obliged to give up to one of his assistants within a few years, in consequence of feeble health. In 1787 he proceeded to Brunswick as counsellor of education, and purchased the *Schulbuchhandlung*, which under his direction became a most prosperous business. He died in 1818. His numerous educational works were widely used throughout Germany. Among the most popular were the *Kleine Kinderbibliothek*, 12 vols., 11th ed., 1815; *Robinson der Jüngere*, 59th ed., 1861, translated into English and into nearly every European language; and *Sämmtliche Kinder- und Jugendschriften*, 37 vols.

CAMPEACHY, or Campeche, a fortified town of Mexico, formerly in the province of Yucatan, but now the capital of a new state to which it gives its name, is situated on the west side of the peninsula on the shore of the Bay of Campeachy, in 20° 5′ N. lat. and 90° 16′ W. long. The town is generally well built, though the houses, chiefly of limestone, are for the most part only one story in height. Its public edifices, several of which are substantial structures, comprise a citadel, several churches and convents, a theatre, a museum, a college, a school of navigation, a hospital, and a custom-house. The port, though of considerable extent, and defended by a breakwater 160 feet long, is very shallow, and vessels drawing more than 10 feet have to anchor upwards of a mile from shore. During the Spanish domination Campeachy had a monopoly of the imports to Yucatan, and it still maintains a fair amount of commercial activity. There is a large trade in logwood (*Palo de Campeche*, or Campeachy wood), and considerable quantities of wax, cotton, hides, and cigars are also exported. Shipbuilding is carried on, and salt and marble are obtained in the neighbourhood. In 1872, 24 foreign vessels entered the port, and 317 engaged in the coasting trade; and in the previous year the customs amounted to £29,133,000. A railway is in course of construction to Minatitlan, a distance of 385 miles. The vicinity is interesting for its Indian remains; and the city itself is said to be "built over extensive artificial galleries or catacombs, supposed to have been devoted by the ancient people [Mazas] to sepulchral uses." See Bancroft's *Native Races of the Pacific States of North America*, vol. iv. p. 265. The Spanish town, founded about 1540 near the older Indian settlement, which at the time of the conquest had about 3000 houses, was captured by the English in 1659, and several times in the same century fell into the hands of the Buccaneers. In the revolution of 1842 it was the scene of various engagements between the Mexicans and the people of Yucatan, in the last of which the latter were signally successful. The population, which numbered 15,500 in 1865, is now nearer 19,000.

CAMPEGGIO, or Campeggi, Lorenzo (1479–1539), Cardinal, was born at Bologna in 1479. He was the son of an eminent lawyer, and for some years was himself engaged in the legal profession. But after the death of his wife he entered the church and quickly attained to high office. For his services to the Papal cause during the reduction of Bologna, Pope Julius II. raised him to the rank of bishop, and sent him as nuncio to Germany and Milan. In 1517 he became cardinal, and two years later he was sent to England to stir up a religious crusade against the Turks. He was unsuccessful in this mission, but received from Henry VIII., in 1524, the bishopric of Salisbury. Towards the close of 1528 he came over to England to assist Wolsey with regard to Henry's contemplated divorce from Katherine. He failed to accomplish anything, and left in the following year. The bishopric of Salisbury was withdrawn from him, and though at a later date (1536) it seemed possible that he might regain it, his expectations were disappointed. He died at Rome in 1539, just as he was about to set out on an embassy to Vicenza.

CAMPER, Peter (1722–1789), a celebrated anatomist and naturalist, was born at Leyden, May 11, 1722. He was educated at the university of Leyden, and in 1746 graduated in philosophy and medicine. After the death of his father in 1748 he spent more than a year in England, studying under the most famous medical teachers in London. He then visited Paris, Lyons, and Geneva, and returned to Franeker, where he had been appointed to the professorship of philosophy, medicine, and surgery. He visited England a second time in 1752, and in 1755 he was called to the chair of anatomy and surgery at the Athenæum in Amsterdam. He resigned this post after six years, and retired to his country house near Franeker, in order uninterruptedly to carry on his studies. In 1763, however, he accepted the professorship of medicine, surgery, and anatomy at Groningen, and continued in the chair for ten years. He then returned to Franeker, and after the death of his wife in 1776 spent some time in travelling. He made the acquaintance of Diderot and Marmontel at Paris, and was received with great respect by Frederick the Great at Potsdam. In 1762 he had been returned as one of the deputies in the assembly of the province of Friesland, and the latter years of his life were much occupied with political affairs. In 1783 he was nominated to a seat in the council of state, and took up his residence at the Hague. His death (7th April 1789) was caused by a violent pleurisy, the effects of which were accelerated by political excitement.

Camper's works, mainly memoirs and detached papers, are very numerous; the most important of those bearing on comparative anatomy were published in three vols. at Paris in 1803, under the title *Œuvres de P. Camper qui ont pour objet l'Histoire Naturelle, la Physiologie, et l'Anatomie Comparée.*

CAMPERDOWN. See Duncan, Adam.

CAMPHOR is a colourless translucent body, having a tough waxy structure, with a specific gravity about equal to that of water, melting at 347° Fahr. and boiling at 400°. It volatilizes readily at ordinary temperatures

giving off that peculiarly pungent aromatic odour which is characteristic of the substance. It is very slightly soluble in water, to which it communicates its warm camphoraceous taste; but it dissolves with facility in alcohol, ether, fixed and volatile oils, naphtha, &c. In its chemical constitution it is analogous to the solid stearoptines deposited by many essential oils, especially such as are derived from labiate plants. By submitting it to the action of oxidizing agents camphor, $C_{10}H_{16}O$, is transformed into camphoric acid, $C_{10}H_{16}O_4$, and if the oxidation is continued it becomes camphretic acid, $C_{10}H_{14}O_7$.

The greater part of the camphor of Western commerce is obtained by distillation from the wood of a tree, *Camphora officinarum*, belonging to the Natural Order *Lauraceæ*. It is produced most largely in the Island of Formosa, the area of production being a narrow belt of debateable land separating the Chinese settlement from the territory held of the aboriginal inhabitants of the island. The preparation of the product is consequently attended with considerable danger, owing to the mutual jealousies and encroachments of the natives and the Chinese. The crude and primitive process of distillation is thus described by Mr E. C. Taintor in his *Trade Report of Tamsui*, 1869:—"A long wooden trough, frequently hollowed out from the trunk of a tree, is fixed over a furnace and protected by a coating of clay. Water is poured into it, and a board perforated with numerous small holes is luted over it. Over these holes the chips [of the camphor-wood] are placed and covered with earthenware pots. Heat being applied in the furnace, the steam passes through the chips, carrying with it the camphor, which condenses in the form of minute white crystals in the upper part of the pots." It is collected and stored in vats to await exportation, during which time it gives out from 3 to 4 per cent. of uncrystallizable camphor oil of a yellowish colour, which has been suggested for use in medicine and the arts in the same way as spirits of turpentine. In addition to the supplies obtained from Formosa, a considerable quantity of camphor is now shipped from Japan. Japanese unrefined camphor is of a lighter colour than that obtained from Formosa, and commands a higher price in the market. Crude camphor is submitted to a process of refining by sublimation from a small quantity of sand, charcoal, iron-filings, or lime. The operation is conducted in glass vessels of peculiar form, to the upper part of which the sublimate adheres. It requires to be conducted with great care on account of the peculiarly inflammable nature of the product, and the heat must be carefully regulated to produce a solid compact cake.

Borneo camphor, or Barus camphor, is a variety differing entirely in its source, being the produce of *Dryobalanops Camphora*, and also somewhat removed in its chemical constitution and physical properties from the ordinary variety. It is obtained in its concrete form in fissures in old trees, which are cut down and split up in search of it. The tree is a native of the Malay peninsula, and is found chiefly in certain parts of Borneo and Sumatra. Borneo camphor is extravagantly prized by the Chinese, who readily pay one hundred times more for this variety than for ordinary camphor.

A third variety of camphor, scarcely known beyond China, but there called Ngai camphor, has been ascertained by the late Mr D. Hanbury to be the product, in part at least, of *Blumea balsamifera*. In chemical composition it is the same as Borneo camphor, but differs from it in respect of odour, greater hardness, and higher volatility. In China it occupies in respect of value an intermediate place between ordinary and Borneo camphor.

Camphor is extensively employed in medicine both internally and externally as a stimulant, but its chief medicinal use is in the preparation of liniments, into the composition of many of which it enters. It has a vulgar reputation as a prophylactic, on which account it is in great demand during serious epidemics. It possesses properties invaluable to naturalists and others for keeping furs, skins, and other animal substances free from moths; and it similarly preserves cabinets of insects from attack. A very large quantity of camphor is consumed in India, and generally throughout the East.

CAMPHUYSEN, Dirk Rafaelsz (1586–1627), a Dutch painter, poet, and theologian, the son of a surgeon at Gorcum, was born in 1586. As he manifested great artistic talent, his brother, in whose charge he was left on the death of his parents, placed him under the painter Govitz. But at that time there was intense interest in theology; and Camphuysen, sharing in the prevailing enthusiasm, deserted the pursuit of art, to become first tutor of the sons of the lord of Nieuport, and then minister of Vleuten. As, however, he had embraced the doctrines of Arminius with fervour, he was driven from this post, and suffered much persecution. His chief solace was poetry; and he has left a translation of the Psalms, and a number of short pieces, remarkable for their freshness and depth of poetic feeling. He is also the author of several theological works of fair merit, among which is a *Compendium Doctrinæ Socinorum*; but his fame chiefly rests on his artistic power. His pictures, like his poems, are mostly small, but of great beauty; the colouring, though thin, is pure; the composition and pencilling are exquisite, and the perspective above criticism. The best of his works are his sunset and moonlight scenes and his views of the Rhine and other rivers. The close of his life was spent at Dokkum, where he died in 1627.

CAMPI, Bernardino, a pupil of Giulio Campi, who adopted a less ambitious style, but is equal and in some respects superior to his master. Bernardino was born at Cremona in 1525, and began life as a goldsmith. After an education under Giulio Campi and Ippolito Corta, he attained such skill that when he added another to the eleven Cæsars of Titian, it was impossible to say which was the master's and which the imitator's. He was also much influenced by Correggio and Raffaelle.

CAMPI, Giulio, the founder of a school of Italian painters, was born at Cremona about 1502, and died in 1572. He was son of a painter, Galeazzo Campi, under whom he took his first lessons in art. He was then taught by Giulio Romano; and he made a special study of Titian, Correggio, and Raffaelle. His works are remarkable for their correctness, vigour, and loftiness of style. They are very numerous, and the church of St Margaret in his native town owes all its paintings to his hand. Among the earliest of his school are his brothers, Vincenzo and Antonio, the latter of whom was also of some mark as a sculptor and as historian of Cremona.

CAMPIAN, Edmund (1540–1581), a celebrated English Jesuit, was born of humble parentage at London in 1540. From Christ's Hospital he removed to Oxford University, where he took a degree and became fellow of St John's. He was admitted to holy orders in the English Church, and in 1567 was ordained deacon. Being convinced that he could not assent to the Protestant formulary required by the Church of England, he left Oxford and went to Ireland, where he occupied himself in writing a history of the country. He then joined Allen and others at Douay, and passed his novitiate as member of the Society of Jesus. After residing for a short time at Brünn, Vienna, and Prague, where he taught philosophy and rhetoric, he was sent by Gregory XIII., along with Father Parsons, on a propagandist mission to England. He arrived in England in 1580, and entered on his duties by challenging the

universities and clergy to dispute with him. In July 158; he was apprehended along with Parsons and two other agents at Lyford in Berks, and thrown into the Tower, on a charge of having excited the people to rebellion, and holding treasonable correspondence with foreign powers. Having been found guilty, he was condemned to death, and was executed at Tyburn, Dec. 1, 1581, with several others of his order. He is admitted to have been a man of great abilities, an eloquent orator, a subtle philosopher, and able diplomatist; and he is praised by all writers, whether Protestant or Roman Catholic, not only for his talents and acquirements, but also for the amiability of his disposition. A full account of the Jesuit mission in which Campian took part will be found in Froude's *History of England*, vol. xi.

CAMPLI, a town of Italy, in the province of Abruzzo Ulteriore I., 5 miles north of Teramo. It has a cathedral, an abbey, and several churches and convents. Population, 7770.

CAMPOBASSO, a city of Italy, the capital of the province Molise, 53 miles N.N.E. of Naples. It is situated on the ascent of the mountain Monteverde, around which it forms a kind of amphitheatre. It is fortified, and contains a cathedral, the ruins of a castle, a small theatre, a hospital, and various other public buildings. The most important industry is the making of steel and cutlery, and there is a considerable export trade in corn. Population, 14,090.

CAMPOBELLO, a town of Sicily, in the province of Trapani, 7 miles E.S.E. from Mazzara. In the neighbourhood are the interesting quarries of Rocca di Cusa, from which the blocks were obtained for the buildings of the ancient Selinus. Population, 5575.

CAMPOBELLO DI LICATA, a town of Sicily, in the province of Girgenti, and 20 miles E.S.E. of the city of that name, on a tributary of the Salso. It possesses valuable sulphur mines. Population, 6301.

CAMPOMANES, Pedro Rodriguez, Conde de (1710–1802), a Spanish statesman and writer, was born in Asturias about 1710, or, according to other authorities, in 1723. From 1788 to 1793 he was president of the council of Castile; but on the accession of Charles IV. he was removed from his office, and retired from public life, regretted by the true friends of his country. His first literary work was *Antiquidad Maritima de la Republica de Cartago*, with an appendix containing a translation of the *Voyage of Hanno* the Carthaginian, with curious notes. This appeared in a quarto volume in 1756. His principal works are two admirable essays, *Discurso sobre el Fomento de la Industria Popular*, 1774, and *Discurso sobre la Educacion Popular de los Artesanos y su Fomento*, 1775. As a supplement to the last, he published four appendices, each considerably larger than the original essay. The first contains reflections on the origin of the decay of arts and manufactures in Spain during the last century. The second points out the steps necessary for improving or re-establishing the old manufactures, and contains a curious collection of royal ordinances and rescripts regarding the encouragement of arts and manufactures, and the introduction of foreign raw materials. The third treats of the guild laws of artisans, contrasted with the results of Spanish legislation and the municipal ordinances of towns. The fourth contains eight essays of Francisco Martinez de Mata on national commerce, with some observations adapted to present circumstances. These were all printed at Madrid in 1774 and 1777, in five volumes. Count Campomanes died in 1802.

CAMUCCINI, Vincenzo (1775–1844), the most famous of the modern historical painters of Italy, was born at Rome in 1775. He was educated by his brother Pietro, a picture

restorer, and Bombelli, an engraver, and, up to the age of pa..irty, attempted nothing higher than copies of the great worksters, his especial study being Raffaelle. As an original care thr, Camuccini belongs to the school of David. His essentia are rather the fruits of great cleverness and patient both person of fresh and original genius; and his style was and prefer.v imitative. He enjoyed immense popularity, He was appually and as an artist, and received many honours and of the Nheuts from the Papal and other Italian courts. of the pictures pinted director of the Academy of San Luca of nearly all the eapolitan Academy at Rome, and conservator of Honour. His of the Vatican. He was also made chevalier the Assassination orders in Italy, and member of the Legion Devotion of the chief works are the classical paintings of Remus, Horatius Cocle of Cæsar, the Death of Virginia, the in mosaic for St Peter Roman Women, Young Romulus and Temple, and a number s, the St Thomas, which was copied Rome September 2, 1844 s, the Presentation of Christ in the f excellent portraits. He died at

CAMUS, Charles Et...

French mathematician and m...enne Louis (1699–1768), a en-Brie, near Meaux, on the echanician, was born at Crécy-age of twelve he was able to m p 25th August 1699. At the at the Collége de Navarre in ssf aintain himself by teaching himself to mathematics, civil a in , Paris, where he devoted astronomy. He became Ass se of nd military architecture, and Sciences, professor of geomet with ociate of the Académie des of Architecture, and memb rine. ry, secretary to the Academy London. In 1736 he acc owing r of the Royal Society of Clairvaut in an expedition to L m h ompanied Maupertuis and of a degree of the meridian, the apland for the measurement service, not only as a geometric l. H when he rendered essential by his remarkable skill in the t on ian and astronomer, but also on the 2d February 1768. He 789), mechanical arts. He died *de Mathématiques* (Paris, 1766), a eyder was the author of *a Cours* mathematical and mechanical subj y of L d a number of essays on medicin ects.

CANA, of Galilee, a village more th of Palestine, remarkable as the birthplace of Nathanael, and the scene of Christ's "beginning of miracles." Its ex mous act site is unknown, but it is evident from the Biblical nar s, Lyo ative that it was in the neighbourhood of Capernaum. By a d be tradition as old as the 8th century it is identified with *Kefr Ke ine*, 52, a na, and by a more modern hypothesis with *Kana-el-Jelil*. nd s The former lies about 4½ miles N.W. of Nazareth, and cont *this p* ains the ruins of a church and a small Christian population; Fra the latter is an uninhabited village about 9 miles N. of Naza In eth, with no remains of antiquity but a few cisterns. surge

CANAAN, a geographical name of archaic Hebre r for origin, generally supposed to mean "depression," "lowland," he and hence fitly applied to various low-lying *districts* of Syria, viz., Phœnicia (Isa. xxiii. 11; Josh. v. *1*, *where the* LXX. has τῆς Φοινίκης), Philistia (Zeph. ii. 5), and the valley of the Jordan (as implied in Num. xiii. *29*, *cf.* Josh. xi. 3). It is, however, also applied to *the whole* of the territory conquered by the Israelites on the west side of the Jordan (Gen. xi. 31, xii. 5; Num. xiii. *2*, *17*, *&c.*), the boundaries of which are given in Gen. xv. *18 as* "the river of Egypt," (*i.e.*, the Wâdy, or torrent-valley, el-Arîsh), and "the great river," the River Euphrates. Probably the Israelites found the name in use in the *Jordan* Valley, and, as a part of this was the first district they conquered, extended it to their subsequent acquisitions. We have good parallels for this extension in the use of Argos for the whole of the Peloponnese, and of Hellas for the mainland of Greece. Of course this theory implies that the original signification of the word had been forgotten as was so often the case with Hebrew proper names. The Phœnicians likewise accepted the name of Canaan. Hecatæus of Miletus (about 520 B.C.) knew Χνᾶ as a

synonym for Φοινικη, and the same identification is found in Philo's *Sanchoniathon* (Müller's *Fragmenta Hist. Græc.*, vol. i. p. 17, vol. iii. p. 369). St Augustine, too, says that the Punic peasants, when asked what they were, replied in Punic, *Chanani* (ed. Bened., vol. iii. col. 932), and on a coin of the date of Antiochus Epiphanes, Laodicea in the Lebanon district is called "a mother, or metropolis, in Canaan" (see inscription in Schröder, *Die phönizische Sprache*, p. 275). It is remarkable that there is a trace, and no more, of the extended use of the word Canaan in Egyptian. The town nearest to Canaan, in the territory of the Shasu or Bedawín (*lit.* Brigands, *cf.* Heb. *shāsūh*), was called Pa-Kanana (Brugsch, *Histoire d'Égypte*, p. 145).

An instance of the confusion produced by the different uses of the term Canaan is supplied by Gen. x. 15–18, where the list of Phœnician cities is interrupted by the five Palestinian nations, the Hittites, Jebusites, &c. As De Goeje has pointed out, the original writer of the Table of Nations understood Canaan in the sense of Phœnicia—he had probably used a Phœnician chart; the interpolator, in that of Palestine (*Theologisch Tijdschrift*, 1870, p. 241).

Why Canaan is placed among the descendants of Ham could only be shown by a chart of the world as known to the Phœnicians. Clearly there was a misunderstanding as to the coasts of the Red Sea.

Compare Movers, *Die Phönizier*, vol. ii. (1), pp. 4–6; Knobel, *Die Völkertafel der Genesis*, pp. 307–310; De Goeje, *Over de Namen Phoenicië in Kanaän*, Amst. 1870. (T. K. C.)

CANAANITES. Only two of the possible senses of the word Canaanite need be here referred to; for the others, see PHŒNICIANS and PHILISTINES. And as one of these is included in the other, let us pass at once to the Canaanites in the larger sense, *i.e.*, the whole group of nations conquered by the Israelites on the west side of the Jordan. The group is variously described. It is sometimes said to consist of five—Canaanites, Hittites, Amorites, Hivites, Jebusites (Exod. xiii. 5); sometimes of six, the Perizzites, *i.e.*, *Pagani*, being added (Exod. iii. 8, 17, xxiii. 23, xxxiii. 2, xxxiv. 11; Deut. xx. 17; Josh. ix. 1, xii. 8); sometimes of seven, by including the Girgashites (Deut. vii. 1; Josh. iii. 10, xxiv. 11); once of ten, omitting the Hittites, and including the aboriginal Rephaim and three Arab tribes, the Kenites, Kenizzites, and Kadmonites (Gen. xv. 19–21). The latter, however, are clearly inserted by mistake, as they only became inhabitants of Palestine, so far as they did become such, as the reward of assistance given to the Israelites. There are only two of these nations about whom we have any collateral information—the Hittites and the Amorites. The former, however, seem also to have been included among the Canaanites by mistake. Historical evidence, both Biblical and extra-biblical, proves convincingly that they dwelt beyond the borders of Canaan; and linguistic evidence tends on the whole to show that they did not even speak a Semitic language (see HITTITES). The latter, too, were not entirely homogeneous with the other Canaanitish peoples, if the notices in Deut. iii. 11 ("Og . . . of the remnant of the Rephaim"), *ibid.* 13; Josh. xii. 4, xiii. 12, may be taken as historical. Perhaps, as Ewald suggests, they were mixed with the aborigines. A Semitic basis seems probable, but has only one linguistic fact in its favour—Senir, the Amorite name of Hermon (Deut. iii. 9), mentioned also in an inscription of Shalmaneser (*Brit. Mus. Coll.*, vol. iii. p. 5, No. 6, l. 45); personal names like Og and Sihon may easily have been Semiticized, and the name Amorite itself, being probably descriptive (see AMORITES), has no ethnological value. They are at all events un-Canaanitish in their political capacity, two considerable states having been founded by them on the east of the Jordan (Deut. iii. 8; Josh. xii. 2; Judg. x. 8, xi. 22). It will therefore be better to exclude Hittites and Amorites from the present notice.

I. It is extremely difficult to draw any distinction between the remaining members of the Canaanitish group. As described in the early books of the Old Testament, they have a general family likeness. They are described as living in a state of political disintegration, the combined result of the Semitic love of independence and of the varied conformation of the soil. Thirty-one of their petty kings are mentioned in Josh. xii. 9–24, including the king of Hazor (afterwards reckoned to Naphtali), whose realm, in Judg. xi. 10, is called "the chief of all those kingdoms." We find, indeed, a king of Bezek claiming to have enslaved "seventy" of the surrounding *reguli* (Judg. i. 7), but this is an altogether exceptional event, for which the loosening of authority produced by the guerilla warfare of the Israelites sufficiently accounts. Yet the isolation of the Canaanites can never have been complete. Like the Phœnicians, they will have had their federations, as appears to be implied by the title Baal-berith, or "Baal of the Covenant" (Judg. viii. 33); and hieroglyphic inscriptions tell of their alliances with the Khita or Hittites against their Egyptian suzerains. Indeed, the rebellious tendencies of the Syrian states will partly explain the inaction of the Pharaohs during the Israelitish conquest. The only injury Joshua could do to the latter would consist in blocking up the military coast-road to the north of Syria, but this was well secured by Egyptian garrisons, which Joshua did not venture to attack; while to get the Canaanites humbled without any trouble was a clear gain. That the Israelites were not immediately and at all points successful is now universally recognized. The work of many years was concentrated by tradition on a single great name; yet the Old Testament itself corrects by numberless indications the error of the more imaginative narrative. Thus the kingdom of Hazor, which had been utterly destroyed, according to Josh. xi. 10, 11, emerges again in the more accurate account of Judges (iv. 2, 3). And both Joshua and Judges (not to descend later—see AMORITES) supply evidence for the continued Canaanitish occupation of many parts of the country (Josh. xiii. 13, xv. 63, xvi. 10, xvii. 12, 13; Judg. i. 19–36). The immediate result of the invasion was, not the extinction of the old, but the addition of a new (and yet not wholly new) element, of stronger stuff but less advanced culture.

Political state.

II. No doubt the Israelites at first put an end to much of which they could not discern the value, or, to use their own phrase, made it a *khérem*, a thing consecrated to God by destruction. The origin of Hebrew literature would not be such a blank if the sacred archives of Kiryath-sépher, or "the Book-city," otherwise called Kiryath-sannah, or "the Law-city (?)" (Josh. xv. 15, 49), had been preserved. Still the attractions of culture were superior in the long run to the dictates of religious zeal. Goodly houses, vineyards, and oliveyards (Deut. vi. 10, 11) were agents more powerful even than chariots of iron. The secrets of agriculture had to be learned from the Canaanites; intercourse naturally led to intermarriage, and so a new strife arose in the field of religion, in which half the Jewish nation perished utterly, and the other half was only saved by its voluntary submission to a spiritual despotism.

Results of the conquest.

III. The pages of the book of Judges are full of complaints of Israelitish infidelity, which is rightly ascribed by the compiler to mixture of blood (Judg. iii. 6). It is true that expressions like this of infidelity have only a limited accuracy. As Ewald and Kuenen have pointed out, the final editor of Judges lived in the age of the Exile, when the religion of Yahveh (miscalled Jehovah) had attained its full development. From his point of view, religious approximation to the Canaanites was wilful apostasy, because it involved the effacement of the distinction between physical and moral religion. But of this distinction the Israelites were hardly more conscious than the Canaanites.

[illegible]

The religions of both nations were based on a feeling for the powers of nature, whether regarded as destructive and awful, as by the one, or as favourable and lovely, as by the other. Thus the one religion was stern and in tendency moral: the other soft and in tendency immoral: there was indeed a difference, but not a clear-cut distinction between them. To come to particulars,—the chief object of Canaanitish worship was the dual-natured god of life and fruitfulness, viz., Baal, or rather the Baal, *i.e.*, "the lord," and his consort Ashérah, *i.e.*, "the happy," and so "happy-making, favourable" (as in Assyrian, Salmanuâsir, "Salman is favourable"). The masculine form is also probably a divine title, and has given its name to the tribe of Asher, as Gad ("good fortune") to the Gadites. As Movers long ago pointed out, Ashérah is not identical with Ashtoreth or Astarte, whose name is philologically different, and who belongs to another type of Semitic religion. Her symbol was the stem of a tree (Deut. xvi. 21; Judg. vi. 25), though this may have been sometimes carved into an image; that of the Baal probably had the form of a cone, and represented the rays of the sun. It is these symbols which are referred to in the phrase, "the Baals and the Ashérahs" (Judg. iii. 7); the "groves" of the authorized version is an evident mistranslation (see in the Hebrew or some accurate modern version, Judg. vi. 25; 1 Kings xv. 13; 2 Kings xxiii. 6). The licensed harlotry which formed part of the worship of Ashérah was profoundly obnoxious to the later Hebrew writers (Num. xxv.; Deut. xxiii. 18), though, indeed, even the folk-lore of the Israelites shows traces of aversion to its attendant immorality. An illustration of this is furnished in the narrative of Sodom (Gen. xviii., xix.), which can only refer to the later Canaanites. Similarly, another writer (Gen. xv. 16) describes "the iniquity of the Amorites" as the divine justification of the Israelitish conquest. It is also the subject of a threatening passage in the Levitical legislation (Lev. xviii.), which if composed during the Babylonian exile, as is held by Graf and Kalisch, is a remarkable evidence of the tenacity of pre-Israelitish customs.

Another characteristic of Canaanitish religion, though far from peculiar to this, was soothsaying. After Israelite prophecy had broken its shell, and taken its daring flight into a more spiritual region, its first anxiety was to destroy that rival phenomenon which enslaved the minds of men to gross superstition. Hence the earnest dehortations of Isaiah (ii. 6), and of the writer of Deuteronomy (xviii. 10–14).

There was only one relic of Canaanitish times which the disciples of prophetic religion could not or would not throw aside—the old traditions. For it can hardly be doubted by uncompromising historical critics that some, perhaps many, of the narratives of Genesis are but purified versions of Canaanitish myths and legends. The most obvious examples will naturally be those stories which are attached to localities in Canaan, *e.g.*, Luz and Beersheba. Of course the story of Melchizedek, "the king of Salem," and "priest of the most high God" (Gen. xiv. 17–24), is not one of these, being out of harmony with all our other notices of the Canaanites. It is also easily separable from the rest of the narrative, and may possibly be as late as the Maccabean period, and written in honour of the temple and its priesthood, which are glorified by being, as it were, prefigured in the patriarchal age.

IV. The question has been asked of late, whether a remnant of the old population of Palestine may not still be in existence. M. Clermont-Ganneau, following Prof. E. H. Palmer (*History of the Jewish Nation*, p. 64), answers it confidently in the affirmative. In the fellahín or peasants of the Holy Land he sees the descendants of the Canaanites, who, having been reduced to a state of serfdom, were contemptuously overlooked by the successive hordes of conquerors. Their strange superstitious customs have been remarked by every close observer, and are evidently survivals of some early form of religion. M. Ganneau also mentions some curious legendary parallels to Biblical narratives existing among them. Dr Thomson (*The Land and the Book*, pp. 226-8) holds a similar theory about the sect of the Nusairíeh in northern Syria, who are equally bad Moslems, but more probably represent the *débris* of the later Syrian paganism.

V. We have yet to speak of the ethnological relation of the Canaanites and the Israelites. The linguistic evidence points to a kinship as close as that of both to the Phœnicians. Not only are the personal names of the Canaanites (Melchizedek, Adonibezek, Adonizedek, Ornan or Aranyah, of which Araunah seems to be a corruption) pure Hebrew, but so too are the names of their cities, an evidence of still greater value, as given both in the Old Testament and in the lists of the places conquered by Thothmes III. The latter have been discovered by Mariette-Bey on a kind of triumphal arch at Karnak; they include 119 names belonging to Canaan, of which 75 have been identified with known Hebrew names of places (Mariette-Bey, in *Comptes Rendus de l'Académie des Inscriptions*, 1874, p. 243, &c.). The same Hebraic character is apparent in the names given in the "Travels of a Mohar" (see the *Records of the Past*, vol. ii. pp. 107–116), which have been illustrated, we understand, by the recent explorations of Lieutenant Conder. How, it has been asked, is this community of language to be accounted for? The problem is a real one to those who regard the Table of Nations (Gen. x.) as an ethnological authority, for in that document the Canaanites are classed separately from the Hebrews among the descendants of Ham. From this, as we believe, antiquated point of view, it becomes necessary to assume that the Canaanites borrowed their language from some of the genuine descendants of Shem. From the Israelites? But they spoke the language long before the Israelite immigration. From an aboriginal Semitic-speaking race? But there is no historical evidence for the existence of such a people. We are thus driven to accept the view that the Table of Nations is arranged not on an ethnological but on a geographical principle. The Canaanites will then be classed among the descendants of Ham as belonging, according to the compilers, to the southern terrestrial zone—not, however, the Canaanites, in our sense of the word, for these formed no part of the original Table (see CANAAN), but the Phœnicians. Apart from this misunderstood document there is no difficulty in admitting the affinity of the three nations, the Israelites, the Canaanites, and the Phœnicians, who all appear to have migrated successively from a Babylonian centre (see PHŒNICIANS). The last to move westward were probably the Hebrews. They are generally supposed to have originally spoken an Aramaic dialect, but after entering Palestine to have adopted that of the more civilized Canaanites (see *Introductions* of Bleek and De Wette-Schrader). The only evidence, however, offered in support of this view is Gen. xxxi. 47, where the "cairn of witness" receives a Hebrew name from Jacob, an Aramaic from Laban. From this it is inferred that Laban's great-uncle Abraham must, according to tradition, have spoken Aramaic, as if Aramaic were as early a development as Hebrew, and as if the writer in Genesis had any thought of illustrating philological problems! Of any such event in the history of the Hebrews we have simply no evidence whatever.

Compare Ewald, *History of the People of Israel*, Eng. trans., vol. i. pp. 232–242; Kuenen, *Religion of Israel*, Eng. trans., vol. i. chap. 1 (with note) and 4; Movers, *Die Phönizier*, vol. ii. (1), pp. 61–82; Knobel, *Die Völkertafel der Genesis*, pp. 202, 321, 332–338; Clermont-Ganneau, "The Arabs in Palestine," in *Macmillan's Magazine*, August 1875. (T. K. C.)

CANADA

Plate XXXV.

CANADA, geographically and politically, differs widely from the British colony known by that name prior to 1867. Before that date the country embraced under the name of Canada included a region about 1400 miles in length and from 200 to 400 miles in breadth, extending from the watershed west of Lake Superior eastward to Labrador. Alongside of it lay the independent British provinces of Nova Scotia, New Brunswick, Prince Edward Island, and Newfoundland, and beyond it to the north and the west the vast regions abandoned to the Hudson's Bay Company But various causes combined to impress on Canadian statesmen the desirableness of uniting the colonies of British North America into one political confederation.

On the cession of Canada to Great Britain in 1763, its French colonists were guaranteed the free exercise of the Roman Catholic religion, and equal civil and commercial privileges with British subjects. Further privileges were secured by "the Quebec Act" of 1774, whereby the old French laws, including the custom of Paris, the royal edicts, and those of the colonial intendants under the French regime, were declared binding in relation to all property and civil rights; while the criminal law was superseded by that of England with its trial by jury. The seignories, with their feudal rights and immunities, were also perpetuated; and thus, under the fostering protection of England, the colonial life of the France of Louis XV. and the regency survived in the "New France" of Canada, unaffected by the Revolution of 1792. But the whole French population at the date of the conquest did not exceed 65,000. From Great Britain, and still more from the older colonies, emigrants hastened to occupy the new territory to the north of the St Lawrence. On the declaration of independence by the revolted colonies in 1776, the loyalist refugees were welcomed by the Provincial Government, settled on land in Upper Canada, and aided with funds and farming implements; and these were followed by emigrants from Great Britain. But it was not till 1791 that the rule of a governor, aided solely by a council appointed by the Crown, was superseded by the grant of a constitution establishing the Government with an elective legislature. At the same time Upper Canada, with its purely British settlers, was made a separate province from the old French colony of Lower Canada. At this date the population of Lower Canada had increased to upwards of 130,000, and that of Upper Canada was about 50,000. According to the first strictly reliable census of 1811 it amounted to 77,000. But the increase of population of Lower Canada was in part due to the immigration of British settlers. In 1793 a Protestant bishop of Quebec was appointed by the home Government; and in 1804 a cathedral was erected for him at Quebec, on the site of the old Recollet church. Dr Jacob Mountain, the Anglican bishop, exerted himself in the cause of education. Parliament enacted the establishment of free schools throughout the parishes of Lower Canada, but to this the Roman Catholic clergy gave resolute opposition: and in various other ways a spirit of antagonism began to manifest itself between the French inhabitants and the British population.

The war of 1812 followed; and during the protracted struggle on the Canadian frontier till the signing of the treaty of Ghent in 1814, the French and British colonists were united in loyalty to England; but with the restoration of peace internal political difficulties revived. The legislative and executive councils were at open variance with the popular representative assemblies; and a new element of strife created antagonism between Upper and Lower Canada. The position of Quebec and Montreal gave to Lower Canada a control over the exports and imports of the country; financial misunderstandings arose between the two provinces respecting their rightful share of import duties; and a proposal, first made in 1822, for a legislative union between Upper and Lower Canada, was at length carried out in 1841, accompanied by important concessions designed to confer on the majority of the representatives of the people that influence over the executive Government which constituted the essential element of responsible government in England. But while the British colonists were divided by the old English party lines, the French Lower Canadians, united by local interests, race, and religion, were able to hold the balance of power whenever the two British parties divided on points of sufficient importance to preclude a compromise. Thus while the advantages of soil and climate, the industry, and the consequent wealth of Upper Canada, enabled it to contribute an ever-increasing proportion of the revenue of the united provinces, it frequently received a very partial share in their distribution, and was liable to be outvoted on questions in which both local feeling and local interests were largely involved. This condition of things was turned to account in the party contests of the time with an ever-increasing irritation and sense of wrong on the part of the British colonists of Upper Canada, until a common feeling overrode party lines, and matters were brought practically to a deadlock.

This it was which led to the idea of a legislative union among the various British American colonies, while reserving to each the control of its own local government; and the common dangers to which they were exposed by results springing out of the great American civil war furnished additional motives to such a union. The leaders of different parties representing the various interests of the provinces, after mature deliberation, agreed to the principles of the proposed confederation, and the Imperial Government responded by giving it the requisite force of parliamentary authority. The Imperial Act, known as "the British North American Act, 1867," provided for the voluntary union of the whole of British North America into one legislative confederation, under the name of the Dominion of Canada. Thus the older provinces have preceded, even by centuries, the Dominion within which they are now embraced, and have a separate history of their own. The Dominion thus constituted consists at present of the old provinces of Upper and Lower Canada, now designated respectively Ontario and Quebec, along with Nova Scotia, New Brunswick, Prince Edward Island, Manitoba, and British Columbia. To it also pertain the territories in the north-west still unsettled, with power to receive them into the confederacy when they acquire the requisite population and organization of provinces. Provision is also made in the Imperial Act for the admission of Newfoundland into the confederacy. It is further provided that the constitution of the Dominion shall be "similar in principle to that of the United Kingdom;" that the executive authority shall be vested in the sovereign of Great Britain and Ireland, and carried on in his name by a governor-general and privy council; and that the legislative power shall be exercised by a parliament consisting of an Upper House, or "Senate," the members of which are nominated for life, by summons under the great seal of Canada, and a "House of Commons," duly elected by the several constituencies of the various provinces in proportion to the relative population of each.

The Act of Confederation came into operation on the 1st of July 1867, at which date the provinces of Ontario and Quebec were united to the maritime provinces of Nova Scotia and New Brunswick. In 1870 the newly created province of Manitoba, in 1871 that of British Columbia, and in 1872 that of Prince Edward Island, were successively admitted into the confederation. A lieutenant-governor and council are to be appointed to administer the affairs of the north-west territories, not yet settled or organized into provinces; and thus the whole of British North America has been organized into a united political confederacy under the name of the Dominion of Canada.

Previous to the confederation of the provinces, Labrador E. of a line drawn due N. of Anse au Sablon, was independent of Lower Canada, and it still remains politically attached to Newfoundland. The tract of country known as Canada till 1867 extended from Labrador westward to the high land beyond Lake Superior, and from the St Lawrence Valley and the great lakes northward to the watershed between them and the Hudson Bay, and embraced an area of 331,220 square miles, lying between the parallels of 41° 71′ and 50° N. lat., and the meridians of 57° 50′ and 117° W. long. This extensive region, which constituted the most important colony of England, is now included in a Dominion which stretches across the North American continent from the Atlantic to the Pacific Ocean, and embraces an area of about 3,500,000 square miles. The vast prairie lands of the great north-west, thus embraced within the Dominion, and out of which the province of Manitoba has been already formed, include the most fertile region of the whole continent. Already immigration is setting steadily in that direction; nor can it be doubted that what has remained till recently a desert, traversed annually by migratory herds of buffalo, and only available as a hunting ground for wild Indians and the trappers of the Hudson's Bay Company, is destined to become the seat of populous provinces, and to constitute one of the chief granaries of the world.

By the addition of the maritime British provinces, included originally within the Acadie of the old French régime, Canada has acquired an extensive line of sea-coast, indented with bays and harbours, offering the most admirable facilities for every branch of maritime enterprise; and to these will, no doubt, be added ere long the island of Newfoundland, with the command of fisheries unequalled in value either in the Old World or the New. The peninsula of Nova Scotia and the island of Newfoundland form the eastern barriers of British North America, closing the Gulf of St Lawrence, and commanding the Atlantic coast, with its ocean trade and its inexhaustible fisheries; while Vancouver Island, and the shores of the neighbouring mainland, stretch along the Pacific coast, with estuaries, inlets, and well-sheltered harbours, awaiting the development of the growing trade of the Pacific. There the rivers abound in salmon; the whale fisheries of the neighbouring ocean already yield valuable returns; and the cod, haddock, and other deep-sea fish invite the enterprise of the young province, and guarantee an inexhaustible source of future wealth.

The people by whom the maritime advantages of the eastern provinces have thus far been enjoyed are peculiarly fitted by origin and training to turn them to the best account. In the early years of the 16th century, when France was striving to outrival Spain in the occupation of the New World beyond the Atlantic, hardy adventurers of Basque, Breton, and Norman blood sailed from Dieppe, St Malo, Rochelle, and other French seaports, and divided among them the traffic in fish and furs of the Newfoundland banks and the Gulf and the River St Lawrence. The discovery of Canada, and, indeed, of the American continent, is justly assigned to John and Sebastian Cabot, who set out from Bristol under the auspices of Henry VII. of England in 1497, and landed on the coast of Labrador seventeen months before Columbus reached the American mainland. But England was slow to avail herself of the advantages of the discovery. In 1524 Verazzano, a Florentine navigator, sailing under the French flag, coasted the new found continent from Florida to Cape Breton, and the whole vaguely defined region was appropriated in the name of Francis I. as "La Nouvelle France." Ten years later Jacques Cartier sailed from St Malo, explored the coasts of Newfoundland, Nova Scotia, and New Brunswick; and for a time the Norman and Breton adventurers enjoyed a monopoly of fish, peltries, and whatever else could reward those pioneers of civilization for their adventurous daring and enterprise.

By such hardy adventurers the maritime provinces were originally settled, before Britain awoke to the importance of the fisheries and other valuable resources of the New World. But she in her turn contributed an energetic body of colonists, including many of Scottish origin; and the war of independence led to a considerable influx of loyalist immigrants from the revolted colonies. War, both then and in 1812, had its usual effect in depressing native industry. But with the return of peace the British provinces entered on a prolonged course of prosperity, very partially affected by the political troubles of 1836–7, or even by the American civil war of 1862 and subsequent years. Half a century ago the population of the whole of British North America was less than 1,000,000; in 1872 that of the four provinces of Ontario, Quebec, New Brunswick, and Nova Scotia, amounted to 3,485,761; and the population of the Dominion now exceeds 4,000,000 of souls.

So long as Canada was detached in government and all political relations from the maritime provinces, and embraced only Quebec and Ontario, with access to the ocean solely by the St Lawrence, which is closed for fully five months in the year, it constituted an inland province, subject to many restrictions, and was to a considerable extent dependent on reciprocal relations with the United States for its foreign trade.

In a "Memorandum on the Commercial Relations, Past and Present, of the British North American Provinces with the United States," submitted to the Government at Washington in April 1874, by Sir Edward Thornton and the Hon. George Brown, as joint plenipotentiaries of Her Britannic Majesty, it is shown that, in the interval from 1845, when a more liberal policy gave encouragement to intimate commercial relations between Canada and the United States, till 1853, the aggregate export and import trade between the two countries rose from $8,074,291 to $20,691,360; and at the same time a large amount of the import and export traffic between Great Britain and the provinces was carried in bond over the canals and railways of the United States. The Reciprocity Treaty was negotiated by the late Earl of Elgin, as governor-general of Canada, and signed on the 5th of June 1854, and it was abrogated in 1866. In the later years of its continuance the civil war in the United States gave a great advantage to Canada, so that in the last year of the treaty the exports to the States amounted to $54,714,383. Yet even then the balance of trade continued to be in favour of the United States; and under the operation of the treaty, New York, Portland, Boston, and other American seaports, were so largely used for the trade of the British provinces, that the transportation traffic sent to and brought from foreign countries, in bond, over the railways and canals of the United States, and in the ocean ships and steamers, of the United States became an important element of revenue to their chief lines of transport.

The effect of all this, at a time when jealousies and heart-burnings had arisen out of the American civil war, led American statesmen to over-estimate the value of such facilities to the British Provinces, and even to conceive that the abrogation of the Reciprocity Treaty, and the restriction of such facilities, would suffice to create a desire for annexation. Happily, experience has led to very different results. In the "Memorandum on Commercial Relations," already referred to, it is remarked :—

"The industry of Canada had been largely directed to the supply of the American market with commodities for home consumption, as well as for foreign exportation, and the repeal in 1866 of the Reciprocity Treaty, under which so vast a trade had grown up, rendered imperatively necessary prompt measures to open new markets for the sale of Canadian produce. These measures were at once taken. Under the influence of the formal notice given by the United States in 1865, of their intention to terminate the treaty, federation of the provinces, then under discussion, was hurried on, and became a *fait accompli* within fifteen months after its repeal. The Intercolonial Railway was at once undertaken, at a cost of over $20,000,000, at the national expense, to secure direct connection to and from the Atlantic ocean, at Halifax and St John, on Canadian soil. Commissioners were despatched to the British and other West India Islands, and to South American States, to promote the extension of direct trade between them and the Dominion. The enlargement of the canals, the improvement of the navigation of the lakes and river St Lawrence, the construction of the Bay Verte canal, to connect the waters of the Bay of Fundy and the St Lawrence, the subsidizing of ocean and river steamship lines, and the promotion of the great shipbuilding and fishery interests, all received a new and vigorous impetus.

"These measures were attended with remarkable success. Only seven fiscal years have passed since the repeal of the treaty, but already the loss inflicted by it has been more than made up, and excellent outlets in new directions opened for Canadian commerce; with an increasing annual proportion of the vast carrying trade formerly done for the provinces by the railways, canals, and steamships of the Republic transferred to Canadian hands. The traffic between the United States and the Provinces at once fell, from an average during the three years before the repeal (according to American official statistics) of nearly $75,000,000 per annum, to an average of $57,000,000 per annum during the first three years following repeal;—the Act of Confederation, too, removed from the category of foreign commerce to that of home consumption the large interchanges of commodities between the several sections of the Dominion; and the aggregate foreign commerce of the provinces consequently fell in the first year after the repeal of the treaty to $139,202,615 from $160,409,455 in the previous year. As will be seen from the following statement, however, the trade of the Dominion speedily recovered from the blow, and the volume of its foreign commerce gradually increased until, in the seventh year from the repeal of the treaty, it reached the great sum (for a people of four millions) of $235,301,203,—being seventy-five millions higher than it had ever reached in any year of the treaty's existence:—

1867.	Total exports and imports of Canada and Newfoundland	$139,202,615
1868.	" "	139,595,615
1869.	" "	142,240,897
1870.	" "	161,275,538
1871.	" "	184,852,006
1872.	" "	205,339,943
1873.	" "	235,301,203
	Total Foreign Commerce in seven years...	$1,207,807,817"

Thus the immediate effect of the repeal of the Reciprocity Treaty was to draw the British provinces into closer union; while, as appears from official returns, the interchange of traffic, which from 1820 to 1866 had been largely in favour of the States, underwent so great a change from 1866 to 1873 as to show a balance against the United States, and in favour of Canada, in value $51,875,008. Wheat, flour, provisions, and other articles, which were formerly sold to New York and Boston houses, are now sent through Canadian channels, direct to the maritime provinces, to Newfoundland, the West Indies, South America, and to Great Britain; and Canada thus enters into competition with the United States in its own foreign markets. Mr E. H. Derby, special commissioner of the United States Treasury, makes this admission as to the effect of the treaty on a single port:—"The commerce of Boston affected by the Reciprocity Treaty exceeds $27,000,000 annually, namely,—imports from and exports to the maritime provinces, $6,000,000; outfits and returns in deep-sea fisheries, $11,000,000; imports of wool, grain, and animals across the frontier of Canada and entered there, with returns, at least $10,000,000." With the union of the maritime provinces to those on the St Lawrence, Canada has passed from the condition of an inland colony, dependent on the good will or the interested aims of a foreign rival, to the position of the fifth maritime nation of the world. The fisheries more than all else have laid the foundation of the industrial progress of the eastern provinces; and in the men who now sail their fishing fleets Canada has acquired the elements of a powerful marine, which, in any national exigency, will be found to add no less to the defensive strength of the Dominion, than it now does to its commercial enterprise.

By right of seniority the province of Quebec claims the first place among the sister provinces of the Dominion, though Nova Scotia may dispute with her the claim of earliest settlement. Among the cities of the Dominion it is probable also that Montreal will retain the pre-eminence by reason of the unparalleled advantages of her geographical position for commercial purposes. In numbers, wealth, and productive industry, however, the foremost rank is at present due to the province of Ontario. Referring to separate articles for a detailed description of each province, we confine ourselves here to what concerns the Dominion as a whole.

Extent.—The Dominion of Canada extends from 45° N. lat. northward to the Hudson Bay, and reaches from the Atlantic to the Pacific Ocean. In superficial extent it is nearly equal to the whole of Europe, and comprises an area of about 3,500,000 square miles. The larger moiety of this, including the territory formerly held by the Hudson's Bay Company, is the property of the Dominion Government. Of this about 120,000 square miles consist of prairie lands with occasional scattered groves and belts of trees along the rivers, admirably adapted for agriculture. A larger tract, consisting chiefly of timbered land, but interspersed with prairies, and well fitted for settlement and farming operations, may be estimated to cover little short of 500,000 square miles. Beyond those two available regions of land, adapted, by soil and climate, for the growth of wheat and other grains, and the rearing of stock, there is a further belt of land, which, though lying in a colder zone, is timbered, clothed with good natural grasses, and as fit for the growth of barley and oats as are many of the less genial regions of Northern Europe which support a considerable agricultural population. This northern belt of timbered land is estimated at little less than 930,000 square miles. All this, as well as much more still uncleared within the various provinces, has to be settled and brought under cultivation; and out of the great prairie and forest lands of the north-west have yet to be fashioned the future provinces of the Dominion of Canada.

Population.—The population of the whole Dominion in 1871, exclusive of Indians beyond the limits of the provinces, was 3,485,761, but to this has since been added the provinces of British Columbia, Manitoba, and Prince Edward Island: thereby increasing the population to nearly 4,000,000. To this a large addition has since been made, both by natural increase and by immigration. The entire population of Canada in 1875 was estimated to amount to 4,000,000, exclusive of Indians, estimated at [illegible].

Indians.—In the older provinces of Canada the Indians have long since been gathered together into settlements, under the care of superintendents and other officers of the Indian department, and in some cases, with industrial schools and other organizations for accelerating their pro-

gress to an equality in all respects with the white settlers. Missions under the care of different Christian churches have also undertaken the work of religious training, and the supervision of their schools. Of the bands of Indians thus settled on their own reserves, accurate statistics are furnished in the annual reports of the Indian Department. But only a vague estimate can be formed of the actual numbers even of the Crees, Blackfeet, Sioux, and other wild tribes which wander in the vicinity of the Red River settlements, or are brought into trading relations with the factors of the Hudson's Bay Company. The following estimate of the Indian tribes throughout the Dominion of Canada is based on the most recent information; and probably forms a fair approximation to their actual numbers:—

Ontario	14,184
Quebec	10,843
Nova Scotia	1,765
New Brunswick	1,386
Prince Edward Island	323
Manitoba and N.W. Territories	23,800
British Columbia	28,500
Rupert's Land	4,500
	85,301

Nationalities.—The nationalities of the population of Canada are in some respects peculiar. The first settlement made by Europeans, as has been already noted, was by the French navigator Jacques Quartier, or as he is now universally styled, Cartier, in 1535. He explored the coasts of Newfoundland, previously discovered by Cabot, and those of Nova Scotia and part of the Gulf of St Lawrence, and took possession of them in the name of Francis I. For two centuries and a quarter thereafter Acadie and Canada were provinces of France; and when, in 1759, they passed to English rule, a French population of 65,000 souls changed their allegiance. Everything was then done, consistent with British honour, to make the change as easy as possible. They were secured in the undisturbed possession of their lands, and in the free exercise of their religion. All ecclesiastical property was respected; and the rights of the church so effectually guarded, that the only remnant of a state church in the Dominion is the Roman Catholic church in the province of Quebec, with its great wealth, its control of education, and its right to levy tithes and other church dues from its adherents. The French laws in like manner remained intact; except in so far as the new subjects of England welcomed the substitution of its criminal law, and trial by jury, for the arbitrary rule of intendants and other representatives of an absolute monarchy. By such means the language and customs of the French population of Canada have been perpetuated, and continue to exercise a marked influence on the character of the country as a whole; though the results of confederation are already tending to diminish this, and to limit the French element to the old province of Quebec. The Canadian population of French descent now numbers 1,082,940; and in the fresh stimulus given in recent years to immigration, strong inducements have been held out to the expatriated inhabitants of the former French provinces of Alsace and Lorraine, to seek a home among the French Canadians of Quebec.

The other nationalities of the Dominion include in the returns of the last census 64,447 natives of the United States in the four provinces of Ontario, Quebec, New Brunswick, and Nova Scotia, who may be assumed to comprise immigrants of English, Scottish, and Irish descent, with an undetermined foreign element. Besides those the Irish population of Canada now amounts to about 850,000, the English to upwards of 700,000, the Scotch to 550,000, the Germans and Dutch to upwards of 230,000, the mixed race of African descent to nearly 22,000; the Welsh to 7800; Swiss, 2962; Norwegians, Swedes, Danes, and Icelanders, 7000; Italians upwards of 1000; and Spaniards, 900. The abrupt emigration of the Icelanders from their remote Arctic home, consequent on recent volcanic disturbances, along with other causes, has led a number of them to seek a home in Canada. The Mennonites, a Russian sect holding opinions closely allied to the Quakers in reference to bearing arms, have left their homes in large bands, and many of them are settling in Manitoba, and other parts of Canada. Added to all those, have to be taken into account the miscellaneous elements of the new population of British Columbia,—Greek, Mexican, Spanish, French, German, Chinese, and Japanese; in addition to which the native Indian population constitutes an important element. The mixture of Indian and White blood has been considerable in the older provinces, and cannot fail to affect largely the population of Manitoba and the North West. Nevertheless in Canada, as in the United States, British race and British institutions alike predominate, and give a tone and character to the people, the influence of which increases after a few generations, as the foreign element is gradually absorbed into the prevailing stock.

The peculiar geographical position of Canada, in immediate proximity to the United States, places it in very different circumstances from Australia, New Zealand, and other British colonies, in reference to immigration. With thousands annually sailing to New York and other United States ports, yet destined for Canada, and many more selecting the route by Liverpool and Quebec to the Western States, it is only by the definite returns of the decennial census that the actual results of immigration can be determined. The following tabular statements compiled from the official reports of the Minister of Agriculture for the Dominion, to whose department the charge of immigration is assigned, and from the returns of emigrant agents, and other sources, will suffice to convey some accurate idea of the rapid increase of the population from this source. The first table shows, in column I., the total number of emigrants from Europe who landed in the St Lawrence during a period of eight consecutive years, from 1866 to 1873. Column II. shows the number of immigrants entering Canada at all points, in so far as they came under the cognizance of immigrant agents, or other Government officials, who were reported to have settled in the Dominion. Column III. shows the numbers who gave a preference to the route by the St Lawrence, and, arriving at Canadian ports, proceeded from thence direct to the United States. The increase in the number of immigrant settlers in Canada within the above period, it will be seen has been five-fold. In reference to the third column there is a compensating element in the fact that, not only many of the better class of emigrants who seek a home in Canada choose the route by New York, and so enter the provinces overland, but the Minister of Agriculture draws special attention to a feature in the returns, showing a direct emigration from the United States to Canada. This is liable to be affected largely by the conditions of trade and industrial progress in either country. In 1873 the number of immigrants from the United States to Canada amounted to 8971 persons.

Year.	I.	II.	III.
1866	28,648	10,091	41,704
1867	30,757	14,666	47,212
1868	34,300	12,765	58,683
1869	43,114	18,630	57,202
1870	44,475	24,706	44,313
1871	37,020	27,773	37,949
1872	34,743	36,578	52,608
1873	36,901	50,050	49,059
Total	289,958	195,259	388,720

The character of the above Canadian immigration as an addition to the industrial population of the Dominion may be partially tested by the following classification of the occupations or trades of the heads of families and other adult males who landed at Quebec during the last-named four years.

Occupations.	1870.	1871.	1872.	1873.
Farmers	4,144	2,989	2,336	1,470
Labourers	12,248	11,465	6,189	6,202
Mechanics	1,717	1,674	6,809	7,662
Clerks and Traders	146	89	79	62
Professional Men	10	4	14	7
Total	18,265	16,221	15,427	15,403

In the year 1872 the total number of emigrants who sailed from British ports, both to the Colonies and to foreign states, amounted to 295,213; but 26 per cent. of the whole were foreigners, availing themselves of the route through Great Britain to their final destinations.

Climate.—The variations of the Canadian climate are less than in many countries of much smaller extent. But throughout nearly its whole area, Canada is characterized by greater heat in summer and a much lower temperature in winter than in corresponding European latitudes. Its general character is level, though it includes the Rocky Mountains, with the picturesque and diversified region lying between them and the Pacific, and the Laurentian range, continued northward to the Arctic Ocean.

Besides the great lakes which find their outlet through the St Lawrence to the sea, there are thousands of lakes throughout Canada, many of them of large dimensions. Foremost among those is Lake Winnipeg. The two great branches of the Saskatchewan take their rise in the Rocky Mountains, and after uniting their streams, flow into this lake, which also receives the Assiniboin, the Red River, and other smaller rivers. The St Lawrence and the great lakes, of which it is the outlet, are estimated to contain 12,000 cubic miles of water; and the Niagara Falls, which constitute the main feature in the descent from Lake Erie to Lake Ontario, are on a scale commensurate with this vast fresh water system of rivers and lakes. The River Niagara issues from Lake Erie in a broad, tranquil stream, varying in breadth from one to three miles, and continuing through a course of about 15 miles, with a fall of little more than a foot per mile. But on reaching the rapids, the descent is suddenly increased to about 80 feet in less than a mile, before the waters reach the grand leap of about 165 feet perpendicular over the great falls. The Horse-Shoe Fall, on the Canadian side is upwards of a third of a mile broad. Between this and the American Fall Goat Island intervenes; and then another volume of water, about 600 feet wide, plunges with like abruptness into the abyss below. The great breadth as compared with the height of the falls tends in some degree to mislead the eye in the first impression produced; and it is only by slow degrees that the mind is brought to an adequate estimate of the grandeur of the scene. Sir Charles Lyell thus describes the effect produced on his mind, at a first glance, and after prolonged study of all their remarkable features:—"We first came in sight of the Falls of Niagara when they were about three miles distant. The sun was shining full upon them—no building in view—nothing but the green wood, the falling waters, and the white foam. At that moment they appeared to me more beautiful than I expected, and less grand; but after several days, when I had enjoyed a nearer view of the two cataracts, had listened to their thundering sound, and gazed on them for hours from above and below, and had watched the river foaming over the rapids, then plunging headlong into the dark pool, and when I had explored the delightful island which divides the falls, where the solitude of the ancient forest is still unbroken, I at last learned by degrees to comprehend the wonders of the scene, and to feel its full magnificence." The river passes over the centre of the Horse-Shoe Fall in a solid column of water of 20 feet; and it is estimated that fifteen hundred millions of cubic feet pass over the falls every minute. This great water system of rivers and lakes affects the climate of the older provinces of Canada; and the other large rivers, with the numerous bodies of fresh water distributed over so large a portion of the whole surface of the Dominion, help to preserve an equable climate, and afford many facilities for local transport.

Reckoning Lake Erie and Lake Ontario with the Niagara River as parts of the St Lawrence, the river system trends in a N.E. direction throughout the whole course from Point Pelee, which is situated in 42° lat., to Tadousac, the earliest French trading port, at the mouth of the Saguenay, in 48° 2' lat. From this the coast still continues to trend northward till it merges in the inhospitable shores of Labrador, in a latitude which is still as far south as London at the Strait of Belle Isle. The degrees of latitude indeed, are a very partial guide to the character of the Canadian climate as compared with that of the British Isles; and any statement of the mean temperatures of the two is deceptive. The severity of the winter, as tested by the thermometer, leads to a very exaggerated impression of Canadian experiences. Owing to the dry, clear, bracing atmosphere which generally prevails, the sense of discomfort produced by the raw easterly winds and damp fogs of an English spring suggests an idea of cold, such as is rarely thought of in a Canadian winter. There are indeed, every winter, a few days of intense cold, as in the summer there are brief periods of equally intense heat, when the thermometer ascends, or descends, through a scale unknown in the more equable English climate. But throughout the greater part of the winter season in Canada the sky is bright and clear, and the weather thoroughly enjoyable. Open sleighs are in use by all. Sleighing parties of pleasure are arranged for the period of full moon, that they may return home over the snow, after an evening's enjoyment at some appointed rendezvous; skating, snow-shoeing, and other outdoor exercises are in universal favour; and the sound of the sleigh-bells in the open thoroughfares adds to the exhilarating sense produced by the pure bracing atmosphere. Snow accordingly brings with it no such ideas of discomfort as are associated with it in England; while by the farmer it is hailed as altogether beneficial. In the province of Quebec the snow begins to lie early in November; in Ontario it is fully a month later; and it differs correspondingly at various localities throughout the Dominion. But everywhere the appearance of the snow is hailed as seasonable and beneficial. It protects the wheat sown in autumn from the frost, affords facilities to the farmer for bringing his produce to market, aids the lumberer in collecting the fruits of his labour in the forest at suitable points for transport by water with the spring freshets, and so contributes alike to business and pleasure.

The following tables, carefully prepared from official reports transmitted to Professor Kingston, director of the Magnetic Observatory, Toronto, from the chief stations throughout the Dominion, supply reliable data for determining the temperature and climatic changes at the most important points throughout Canada and Newfoundland. In the column of first frost at Montreal, as shown in the last of the tables, the dates for the years 1872, 1873, and 1874 indicate the first fall of the thermometer to 32°, while the earlier dates mark the first hoar frost of the autumn.

Mean Temperature (in degrees Fahr.) for each Month and for the Year in the several Provinces, and for certain Stations in the Dominion of Canada.

As will be seen from the previous tables, January and February are the coldest months of the year. Throughout the whole of Canada steady sleighing is reckoned upon during those months. In Quebec and in Manitoba a longer period of sleighing can be relied upon. In Nova Scotia, New Brunswick, and Prince Edward Island, and also on the Pacific coasts, the temperature is modified both in summer and winter according to vicinity to the sea. Abrupt changes of temperature occur both in summer and in winter. A period of great cold early in the month of January is so frequently followed by a complete change that its periodicity is reckoned upon under the name of the January thaw. Snow finally disappears in Quebec about the middle of April. In Ontario it is generally gone a month earlier. The table of average fall of snow given above shows its prevalence at various central points in each of the provinces of the Dominion, from October to the end of April.

Ploughing usually commences in Ontario about the middle of April and in favourable seasons is prolonged into the month of December. But throughout the Domi-

nion, stretching as it does across the continent, and embracing an area nearly equal in size to Europe, the period varies with the locality, and is affected by the vicinity of the great lakes or other local influences. Cattle are turned out to graze in April, feeding in part upon the tender shoots of the spring forest growth, until the appearance of the young pasture with the disappearance of the snow. Before the end of July harvest begins; and with the rapidity of growth under the warm Canadian skies, the hay, grain, and root-crops follow in swift succession; the cleared land is brought again under the plough, and the autumn sowing of wheat is carried on till another abrupt change brings the season to a close. In this way the Canadian climate is marked by the striking contrast of two seasons—summer and winter,—bringing with them alternations of fruitful labour and of repose intermingled with profitable industry and pleasure. This characteristic prevails with slight variations throughout the greater part of the Dominion. Manitoba presents in this respect no marked diversity from Quebec or Ontario. Spring opens nearly at the same time from Red River to the Athabasca. Early in April the alders and willows of the Saskatchewan country are in bloom; the prairie anemone covers the southern exposures to the very verge of the retreating snow. May there brings with it more of the true summer heat than in the provinces on the St Lawrence. But the nights are cool, and throughout the period of greatest heats, the cool night breezes beget a welcome and refreshing change, accompanied with heavy dews. This protects the cereals from the effects of drought even in the driest seasons, and produces a rich growth of prairie grass, making the climate peculiarly favourable for the stock farmer. The Rev. Professor Bryce, of Winnipeg College, thus writes: "The juncture of the seasons is not very noticeable. Spring glides insensibly into summer, summer into fine autumn weather, which, during the equinox, breaks up in a series of heavy gales of wind accompanied by rain and snow. These are followed by that divine aftermath, the Indian summer, which attains its true glory only in the north-west. The haziness and dreamy fervour of this mysterious season have often been attributed to the prairie fires, which rage over half a continent in the fall, and evoke an enormous amount of heat and smoke." His own observations incline him to accept this explanation. Winter begins with crisp clear weather, which grows increasingly cold and cloudy. The wind wheels to the north-east, and with it comes the snow, and the long steady winter of the Canadian year.

The character of the Manitoba winter is thus described by the same intelligent observer:—"The winters of the north-west, upon the whole, are agreeable, and singularly steady. The moccasin is dry and comfortable throughout, and no thaw, strictly speaking, takes place till spring, no matter how mild the weather may be. The snow, though shallow, wears well, and differs greatly from eastern snow. Its flake is dry and hard, and its gritty consistence resembles white slippery sand more than anything else. Generally speaking, the farther west the shallower the snow, and the rule obtains even into the heart of the Rocky Mountains. In south-western Ontario the winter is milder, no doubt, than at Red River; but the soil of the north-west beats the soil of Ontario out of comparison; and after all, who would care to exchange the crisp, sparkling, exhilarating winter of Manitoba for the rawness of Essex in south Ontario."

But the frosts of spring and autumn, not those of winter, are what the Canadian farmer learns to regard with any dread; and this is still more true in reference to the Canadian fruitgrower. But in this respect the north-west climate is exceptional in its character. Frosts are common there in the nights of September; but the fact has been noted by many independent observers, that frost which would injure grain in many other countries, appears to be innocuous on the Red River and the Saskatchewan. Various reasons have been assigned—such as the dryness of the atmosphere, the heat-retaining character of the soil, and the sudden change of temperature that enables vigorous plants to bear an atmosphere at 20° better than at 35° when the latent heat of the earth and the plants has been given off. But whatever be the true cause the fact appears to be well attested. The chief lesson which experience has taught the farmer is to sow his wheat early in the spring, so that the ear shall be past the milky stage before the frost comes.

The climate and other conditions to the west of the Rocky Mountains are necessarily marked by much greater local variations owing to the broken character of the country, with its ravines and deep narrow valleys. Stock raising has hitherto largely occupied the attention of the farmers on the Pacific slope, where the farms are called "ranches," after the fashion of the stock farmers of California and New Mexico. The ground produces both cereals and vegetables where irrigation is resorted to, as in the plains and valleys of those states. But the rich natural grass which abounds furnishes nearly all that is needed for the profitable raising of stock; and until a large female immigration restores in some adequate degree the natural proportion of the sexes, the rough life of the "ranch," with its "corral," or cattle-pen, will be preferred to the more settled industry of the agriculturist.

The capacity of the different provinces for profitable industry, and the character of their native productions, will be found set forth in detail in the separate articles on each province. It is vain to attempt any detailed account of the soil and other local specialties of half a continent. The Geological Survey, carried out under the able direction of the late Sir W. E. Logan and his successor Mr A. R. C. Selwyn, has largely contributed to an accurate knowledge of the agricultural capabilities, as well as the mineral resources of the country. Vast areas consist chiefly of loam, with a substratum of gravel, overlaid throughout extensive tracts of forest by a rich vegetable mould, the accumulation of ages. The prairie lands are not less available; and they are now being surveyed and explored, alike for the requirements of the settler and for economic and scientific results.

The Reports of the Geological Survey of Canada embody in this way a readily accessible guide to the resources of the country, and the suitability of its various districts and provinces for settlement. Entire districts of many square miles in extent prove to be composed of alluvial deposits from 30 to 40 feet deep, of soil in places so rich as to bear good crops of wheat for successive years without manure. Others of nearly equal value are found resting on red sandstone, trap, serpentine, limestone, and other strata most favourable for agriculture. There are also, as along some of the rivers, for miles in succession, soils too rich for wheat, others of a good sandy loam, suitable to and requiring the usual English rotations. In many parts, on the other hand, there exist considerable tracts of poor, thin, and stony soils. The Reports of the Geological Survey, in presenting an account of the geological distribution of the various strata, and their agricultural capabilities, will prove of great value to the immigrant, as well as to others interested in the lands of Canada.

The soil and climate of Canada are such that the country produces a much greater variety of grains and fruits than is usually grown in Great Britain or Ireland. Besides wheat, barley, oats, rye, pease, turnips, potatoes, hemp, flax, hops, and the other ordinary agricultural products of

England, which are all raised in abundance, Canada grows tobacco, rice, maize or Indian corn, and fruits of warmer climes than the British Islands. The full and steady heat of the summer matures with surprising rapidity the most valuable productions, while the long period of repose of the Canadian winter is not only amply atoned for by the rapid and luxuriant vegetation of the summer, but, no doubt, contributes to such results.

Fruits and Vegetables.—The fruits of Canada embrace all that are familiar to the English gardener, with others which the summer there is not warm enough to bring to maturity. The finest melons are grown in abundance in the open ground. In favourable seasons peaches are plentiful in the Niagara peninsula, and in the south-western portions of Ontario, along the shores of Lake Erie and the Detroit River. The vine is cultivated largely in open gardens. The Isabella, the Delaware, Clinton, and other varieties of grapes attain to perfect size and excellent flavour in the open air; and the manufacture of native wines is now successfully prosecuted to a considerable extent.

Wild fruits abound in great variety throughout many Canadian districts. The wild vine (*Vitis vulpina*) is abundant everywhere, twining its tendrils around the trunks and over the branches of the forest trees, and yielding clusters of small grapes, inviting to cultivation. Among the other wild fruits may be mentioned plums, cherries, raspberries, brambles or blackberries, strawberries, whortleberries, blueberries, gooseberries, black and red currants, juniper berries, cranberries, hickory and hazel nuts, and walnuts. The raspberries ripen in such abundance that enormous quantities are annually preserved and sold both in the Provinces and the United States. The blueberry is also extensively sold; and the wild strawberry furnishes an agreeable dessert in many parts of the eastern provinces throughout the latter part of July and August.

Apples and pears are now largely cultivated. The island of Montreal has long been famous for its fruits; and the annual produce of the orchards of Ontario is exported to the States and to Europe. Vegetables for the table are also successfully cultivated in greater varieties than in England, and in such quantities that they are largely exported. The tomato flourishes and yields an abundant crop. Cauliflower, vegetable marrow, squash, French beans, pease, lettuce, spinach, celery, asparagus, rhubarb, and all the more common vegetables are grown in abundance in the older provinces. The climate of Manitoba, notwithstanding its exceptionally low temperature from December to March, gives promise of equally satisfactory results. Professor Bryce, after noting such examples of agricultural produce as that of one old settler who obtained 420 bushels of wheat from 11 acres, and another who by garden culture produced the enormous yield of 134 bushels per acre of oats, thus proceeds: "These are given both as proof of the capabilities of the country, and of the advantage of careful culture. The ordinary table vegetables are surprising in their growth, and reach a prodigious size. The writer has seen nothing in his previous experience equalling the vegetable production of the province; and the late lieutenant-governor, Hon. Mr Archibald, after testing the matter in his own garden, gave the same as his experience."

The exports of fruit and vegetables, the growth and produce of the five eastern provinces of Canada, for the year 1874, included fruit to the value of $128,904, and vegetables to the value of $332,068. But while this produce of the finer fruits and vegetables for the table shows exports to the value of $460,972 in a single year, and thus bears evidence to the character of the soil and climate, it conveys a very imperfect idea of the actual produce of Canadian orchards. Apples especially are in constant use at the table. Throughout the southern portion of Ontario thousands of acres are planted with fruit-trees, yielding valuable crops of the finest quality, and forming an ever-increasing source of wealth to the farmer.

Flowers.—The flora of Canada naturally comes in order along with its agriculture and garden produce; but to deal with the subject effectually would require a botanical treatise on the whole flora of North America. There is the rich flora of the forest, which disappears with the clearing of the land for purposes of agriculture, and is even replaced in part by an immigrant flora, brought in with the hay and grass seeds of the European settler. Again, there is the brilliant flora of the prairies, which, in the full season of summer bloom, are resplendent with blue, scarlet, and yellow petals. The Rocky Mountains, and the rugged slopes of the Pacific province, have also their characteristic flora; while the shallows of the lakes and rivers abound with beautiful aquatic plants, foremost among which is the *Nymphæa odorata*, the magnificent sweet-scented white water-lily, which converts many a broad lagoon into a beautiful floating garden.

It will better accord with the practical aim of this article, to note that the honey-bee flourishes in all the provinces of Canada; aud, as will be seen by the following table showing the produce of a single year, is cultivated with profitable success in the four older provinces:—

	Hives of Bees.	Pounds of Honey
Nova Scotia.	3,038	21,374
New Brunswick	5,854	90,004
Quebec	41,295	648,310
Ontario	94,604	1,239,612
Total	144,791	1,999,300

Forests.—The forests of Canada abound in fine timber, adapted to almost every variety of useful or ornamental work, and furnishing one main element of wealth to the province. Foremost in point of utility are the white and red pine, annually exported in large quantities to the United States and to Europe. Three-fourths of the square and flatted timber produced in the Ottawa region in 1873 was of white pine. Cedar, red pine, and railway-ties chiefly made of tamarac, were the others which were produced in largest quantities. Pine trees of 100 feet high are not uncommon; and instances are not rare of trees greatly exceeding that height.

The pine prepared for exportation is made into squared timber, measuring from 60 to 70 feet in length; or into waney timber (as it is called when only partially squared or flatted), averaging generally the same lengths though sometimes running to 100, or even 120 feet. For the native market the unsquared log is cut into convenient lengths of from 12 to 15 feet for the saw-mill. The white oak, besides being made into squared timber not greatly inferior in dimensions to the white pine, serves also largely to supply staves both for the English and the West Indian markets. The number of pieces of squared and flatted timber produced in the Ottawa district alone in 1873 was 303.268, and the number of unsquared logs for the same year amounted to 2,024,980. The elm, beech, ash, maple, walnut, cedar, birch, and tamarac are all valuable products of the Canadian forests. The black walnut and the birds'-eye and curled maples are now in special demand in England for cabinet and fancy work. The sugar maple is also of value for the sap which it yields during early spring, from which excellent sugar is made in ever-increasing quantities. The yield of maple sugar produced in the four older provinces in 1871 amounted to 17,276,000 lb. A maple grove, as it is called, is accordingly regarded as a valuable feature on a Canadian farm.

The value of the immense forests of Canada is becoming more apparent every year. The year 1874 was one of reduced exports and imports, as compared with any previous year since the confederation of the provinces. Nevertheless the total produce of the forest exported during that year, apart from what was required for use within the Dominion, amounted in value to $26,817,715. Of this timber to the value of $14,928,403 was exported to Great Britain; the United States received to the value of $9,654,890; South America to the value of $920,309; the British West Indies to the value of $602,487; and the remainder went to the Spanish, French, and Dutch West Indies, to France, Portugal, Belgium, Germany, and Holland, and to regions and colonies beyond the Pacific. Australia took to the value of $60,081; China, $38,024; British and Dutch Guiana, $23,452; and Honolulu, the Azores, South Africa, and other countries, in lesser proportions. In addition to all this, the forest produce required for home consumption during the same period cannot be estimated at a less value than $3,000,000.

Canada is becoming every year more important as an agricultural country. It is exporting not only grain but also cattle to the English market; and when the rich prairie lands of the North West are brought under cultivation its agricultural produce will probably rank foremost in value of that of any nation in the world. But at present the produce of the Canadian forests exceeds in value any other yield of the growth, produce, or manufacture of the Dominion. The total value of the exports of Canada for 1874 amounted to $73,926,748; and of this $26,817,715 was the produce of its forests. The importance of this branch of native industry cannot therefore be overlooked. The Governments of the different provinces grant licences to those engaged in the timber trade to cut timber over vast tracts of land, under the name of "timber limits." These are in most cases remote from the settlements; and much ability and foresight are required to make adequate provision for the large bodies of men, horses, and oxen, to be employed in cutting down and preparing the timber for the market, and transporting it to suitable points for rafting. Much capital is accordingly embarked in the trade. Hay and other requisites have to be accumulated at suitable stations. Large gangs of lumberers follow at the proper season. Lumber shanties are constructed capable of accommodating from 25 to 50 men. The structure is made of logs hewn on the spot, and forms a square or oblong edifice surrounded on three sides with the baulks, or sleeping-berths, of the men, while the fourth side is occupied by the dresser or working-table and other requisites of the cook. The centre is open to the sky, and underneath this only opening for light or air a huge wood fire is kept constantly replenished. Over it stretches the crane on which the cook hangs his pot; and thus the fire answers the double purpose of warming and ventilating the dormitory and cooking the food of its inmates. The shanty-cook is an important member of the little community. Salt pork and beef, pease-soup, wheaten bread and tea, with potatoes, white beans, and onions, are the staple of the lumber-shanty fare. As a rule, intoxicating liquors are absolutely excluded; and thus provisioned the foreman selects the proper trees, and lumbering operations proceed throughout the winter. Many thousands of men are busy through the whole winter felling the trees, cutting them into logs, or hewing them into squared timber, and transporting them over the snow to suitable points for floating them down the rivers to the mills, or directly to the place of export. As the rivers are in many places interrupted by falls of a character unfitted to the safe passage of timber over them, large sums are expended in constructing timber-slides; and on some of the main channels, as on the Ottawa, the construction and maintenance of the chief timber-slides are undertaken by the Government.

It is erroneously supposed by many, who are unfamiliar with the character of the Canadian forest, that the work of the lumberer results in the clearing of the land. Only the finest full-grown trees are selected for the lumberer's axe, and it is calculated that the same district may be gone over by the lumberer every twelve or fifteen years. Hence if the destructive fires which from time to time do such immense injury can be guarded against, and the operations of the lumberer are carried on with due care, under proper oversight, there is no reason why the forests of Canada should not remain a permanent source of national wealth.

In the new clearings in the vicinity of lumbering districts, the farmer finds a ready demand for all his produce, and employment for himself, his horses, and his oxen during the leisure of winter. In this way the lumbering business helps to promote the settlement of new districts, and attracts a population to localities which otherwise might long remain a wilderness. In free-grant districts, as in the Muskoka region on the Georgian Bay, where new settlers are engaged in their first hard struggle to transform the wilderness into fruitful farms, the earliest savings of the farmer are frequently expended on a yoke of oxen; and thus provided, his services are welcomed by the lumberers, and he can find profitable employment throughout the winter. On the breaking up of the frost in spring the produce of the winter's lumbering is floated down the rivers. There, at suitable points on every available rapid or waterfall, large mills are erected for sawing up the logs, chiefly for the English and American markets. The squared timber for the foreign markets is put together in cribs and run down the rivers to suitable points, where they are formed into great rafts, and so floated down the lakes and rivers, as on the River St Lawrence to Quebec. There they are finally broken up, and shipped for their foreign destinations.

Few among the many sights which meet the eye of a voyager on the St Lawrence are more striking than one of those floating villages, consisting often of 150,000 cubic feet of timber, bound together into one great raft, with its shanties, its blazing fires, securely kindled on an earthen hearth, and its banners streaming in gala fashion, as it glides along. Much skill is required in piloting these rafts down the great rivers. The cribs floated from the far inland timber limits are collected into what are called drams; each dram has its own gang or division of the raft's crew, and so many drams form a raft. But at every considerable rapid the raft is again broken up into its component parts, and the cribs taken down separately, to be again put together on reaching smooth water. Thus united, the raft moves onward with the current, aided at times by sail and oar, until it is safely secured within the booms of the great timber merchants in the coves above Quebec.

Animals.—Looking to the native fauna of Canada in an economic point of view, it is abundantly evident that the animal life of its seas and rivers is one of its great and inexhaustible sources of wealth. Alike on the sea-coasts, in the estuaries, and throughout its great inland lakes and rivers, the most valuable fish abound; and on the Labrador coasts and those of Newfoundland the seal fisheries are another annual source of wealth. The sturgeon is caught in Canadian waters, frequently weighing from 80 to 100 lb; the finest salmon abound both in the eastern rivers emptying into the Gulf of St Lawrence, and in those of British Columbia; lake trout is caught in large quantities weighing from 10 to 40 lb; and the smaller rivers and lakes teem with beautiful speckled trout, frequently weighing from 4 to 6 lb. The white fish and maskinonge are

esteemed for their delicacy and richness of flavour; and the returns of the fisheries, as given in the separate accounts of the various provinces, show the relative abundance of cod, haddock, mackerel, herring, salmon, halibut, white fish, and other produce of the Canadian fisheries.

The returns of the last census show that in 1871 Canada produced 82,844 quintals of cod and haddock, and 685,272 barrels of fish of various sorts, besides 678,894 gallons of fish oil; and the total value of the produce of the fisheries exported during the fiscal year 1874 was $5,292,368. The quantities here stated are exclusive of the valuable fisheries of Newfoundland, which employ large fleets, and yield a corresponding return from cod, salmon, herring, mackerel, and other fish, from the oil of the whale and cod, and from seal-skins.

Neither British Columbia nor Manitoba has yet been brought within the provisions of the Fisheries Act; and the total yield of their fisheries can only be approximately estimated. Valuable oyster beds exist on the Pacific coasts of the Dominion. The salmon fishery promises, if rightly protected and regulated, to prove a valuable branch of industry. During the year 1873, 195 tons of salmon were canned for export; and 4000 barrels were salted. In the great lakes and rivers of Manitoba the white fish are no less abundant; and they constitute an important source of supply of food in certain seasons of the year throughout the whole North West. The total value of the yield of the fisheries of the Dominion for the year 1874 was estimated at not less than $11,000,000.

Canada has been esteemed from its earliest discovery for its valuable fur-bearing animals, and was prized chiefly on this account so long as it remained a dependency of France. In 1670 Charles II. granted the charter to the Hudson's Bay Company, whereby they acquired the exclusive right of trading with the Indians in the vast regions vaguely recognized as surrounding the great inlet from which the company took its name. In 1783 a rival company was established under the name of the North-West Company, which claimed that, as the Royal Charter of their rivals had not been confirmed by Parliament, all British subjects were free to engage in the fur trade of the North-West The results of the jealousies and hostilities of the two companies played an important part in the early history of Canada, and in the first attempts at settlement on the Red River, which paved the way for the rise of the new province of Manitoba. After many bitter contentions, and after impeding each other's operations for years, the rival companies at length effected a junction in 1821; and the fur trade has since been successfully prosecuted under their joint action, till the acquisition by Canada of the north-west territory as a necessary step towards the prosecution of the plans of confederation, and the formation of new provinces throughout British America.

There still remains, however, not only a vast extent of unoccupied territory in which for many years to come the hunter and the trapper will find undisturbed sway, but the regions around the Hudson's Bay, and stretching westward to Alaska and northward to the pole, must ever remain a shelter for fur-bearing animals, and a resort of the hunter. All the furs collected for the great fur company are shipped to London:—in part from their factories of York Fort and Moose River, on the Hudson's Bay, which are visited by a ship from England every year, and in part from Montreal and Columbia River.

In the vicinity of Canadian clearings deer are still found in abundance, and venison is plentiful during winter in all the markets of Canada. But wherever the deer abound wolves are sure to follow; and wherever they occur sheep-farming is impossible, and their depredations on the farmer's stock make them an object of special dislike. In order to encourage their extermination a premium is paid by Government for the head or scalp of each wolf produced to a local magistrate, and it is not uncommon in new districts for the settler to pay his taxes in wolf scalps. By this means they rapidly disappear from the neighbourhood of the settlements. The bear is another mischievous native of the Canadian forests. The winter furs both of the bear and the wolf are prized for robes; and their value furnishes an additional stimulus to the extirpation of both wherever the country is settled. Beyond the settlements, in the remote recesses of the uncleared forest, the beaver still abounds. Foxes of diverse kinds (silver, grey, red, and black), racoons, otters, fitches, martins, and minks are no less abundant. The musk rat is to be met with on all the Canadian rivers; and the red, black and grey squirrels sport everywhere in the forest, and at times even invade the clearings and make free with the farmers' crops. In the more remote regions, now also being invaded by settlers, vast herds of buffalo are met with; and beyond them are the moose, the wapiti, the reindeer, the white Arctic fox and the polar bear, whose haunts are safe from the invasion of the settler, however rapidly the Dominion may extend, and carve out new provinces in the great wilderness of the North-West.

The total value of the furs exported from Canada in 1871 was $1,633,501. This is distinct from hides and other products of the farm. In the abstract of the value of goods, the growth, produce, and manufacture of Canada, exported from the Dominion during the fiscal year 1874, animals and their products are classed under one head, showing a total value of $14,679,169. This includes a classification of farm and dairy produce along with the products of the chase, the chief items of which may be stated as follows, the same being exclusive of all home consumption:—

Animals and their Produce.			Value.
Horses	number	5,399	$570,544
Horned Cattle	,,	39,623	951,269
Sheep	,,	252,051	702,504
Swine	,,	6,983	56,824
Poultry			79,224
Pork, Beef, and other meats	cwt.	300,003	2,172,591
Butter, Cheese, and Eggs			6,731,105
Lard and Tallow	lb	3,232,458	306,860
Hides, Pelts, Hams, and Hoofs			394,069
Wool	lb	2,764,796	983,845
Furs, dressed and undressed			1,633,501

Cultivated Land and Agricultural Products.—Canada is pre-eminently a country of yeoman farmers. The land is held in possession and tilled by the settler on his own account; and with every addition to the numbers of its industrious population fresh acres are recovered from the wilderness, and added to the productive resources and the wealth of the Dominion. The number of persons occupying land within the four provinces of Nova Scotia, New-Brunswick, Quebec, and Ontario according to the census of 1871 was in all 367,862. Of these there were 324,160 owners, 39,583 tenants, and only 2119 farm labourers or servants. Those facts alone suffice to illustrate the striking contrast between the condition of Canada and most of the countries of Europe. By patient industry and frugality it is in the power of every Canadian to become owner of a house, and proprietor of whatever amount of land he can turn to profitable account; while the character of the population resulting from this condition of things checks the accumulation of extensive landed estates in the hands of single proprietors. The majority of the farms are small, tilled by the proprietor with his own hands, with the help of his sons and occasional hired labour in the busy season

of harvesting. But capital is also successfully applied to farming, and beautiful large stock farms are now entering into rivalry with those of the United States and even of England. The following table shows the extent of holdings, and the subdivision of land:—

10 acres and under	40,281
10 „ to 50 acres	78,877
50 „ to 100 „	141,300
100 „ to 200 „	82,176
Above 200	25,228

The greater number of occupiers and owners of holdings of ten acres and under are to be found in Quebec and the Acadian settlements of the maritime provinces, where a continual subdivision goes on among families under the influence of old custom and the operation of the French law of inheritance. In Quebec the old French seigniories established and perpetuated a large class of landed proprietors with their tenant farmers; and notwithstanding the abolition of the seigniorial tenures in 1854, their influence still survives, so that the number of holders of land above 200 acres is greater in Quebec than in any of the other provinces. The climate and other attractions of Upper Canada tend to secure to it the largest share of immigration; and the rapidly increasing quantity of cultivated land in the province of Ontario is at once an evidence and a guarantee of the substantial progress of the country. In 1842 the population of Upper Canada numbered 486,055, with 1,927,816 acres of land under cultivation. In 1852 the population had increased to 952,004, and the land under cultivation to 3,697,724 acres. According to the census of 1871 the total population of Ontario, as it is now called, numbered 1,620,851, with 16,161,676 acres of land in process of improvement.

Besides the grand staple of the cereal grains, the Canadian farmer derives large returns from his crops of hay, clover, and grass seeds, carrots, mangel wurzel, beans, hops, flax, hemp, and tobacco. In 1852 Upper Canada produced 764,476 ℔ of tobacco, the greater portion of which was grown along the western shores of Lake Erie, and on the peninsula between that and Lake St Clair, where the soil and climate specially favoured its growth. At the same date Lower Canada produced 488,652 ℔; but in 1871 the returns for the province of Quebec alone amounted to 1,195,345 ℔ of tobacco. Hops are cultivated with still greater success; and flax and hemp are additional sources of profit to the farmer. The value of the hops, flax, and flax seed exported during the year 1874 amounted to $161,908. The following tabular statement of the values of some of the chief agricultural products exported during the year 1874, apart from the amounts retained by Canada for home consumption, will suffice to illustrate the increasing value of this important branch of native industry:—

Wheat	bushels	6,581,217	$8,886,077
Barley, Rye, and Oats	„	4,746,820	4,532,669
Indian Corn	„	235,864	81,224
Flour	barrels	540,317	3,194,672
Meal	„	53,162	230,820
Flax	cwt.	782,054	113,256
Flax and other Seeds	bushels	19,088	12,306
Peas and Beans	„	1,807,208	1,526,689
Hay	tons	26,725	293,210
Hops	℔	169,726	40,177
Bran	cwt.	13,898	27,992
Tobacco	℔	125,844	3,568
Fruit and Vegetables		...	460,993
			$19,403,653

The total value of the grain and other agricultural produce of Canada exported during the year 1874, apart from the produce for home consumption, was $19,590,142, of which Great Britain received to the amount of $9,867,047, the United States $8,680,997, and the remainder was distributed as shown here:—

Great Britain	$9,867,047
United States	8,680,997
France	159,600
Belgium	92,000
Newfoundland	595,909
British West Indies	37,427
Spanish West Indies	29,343
French West Indies	4,490
Danish West Indies	7,240
Dutch West Indies	1,373
St Pierre	64,164
Madeira	1,812
British Guiana	15,617
St Domingo	3,123
Total	$19,590,142

But a false estimate of the actual agricultural resources of Canada is apt to be produced by testing them by its exports. Canada is a country of yeoman farmers tilling their own lands and living in abundance on the produce. The requirements for the table of the farm labourer are on a scale consistent with the resources of the country. The home consumption is accordingly great as compared with the number of the population; and it is therefore impossible to estimate, even approximately, the total annual value of all kinds of produce resulting from agricultural labour within the Dominion.

Minerals.—The mineral resources of Canada have as yet been very partially developed. Quebec and Ontario are devoid of coal, though both have access by convenient transport to rich coal-fields in adjoining provinces or states; but the maritime provinces, Manitoba, the north-west territories, and British Columbia are all rich in coal. Other valuable mineral resources are still turned only to the most partial account; but as the work of the Geological Survey proceeds, new fields are opening up for enterprise every year. The rich silver ores of Lake Superior have already yielded wonderfully valuable results to the miners; and the neighbouring districts are now being carefully surveyed. Extensive tracts of gold-bearing quartz are also reported, and Mr Bell, who took the charge of the Geological Survey on Lake Superior in 1872, states that within the basin of the Neepigon, which extends to about 170 miles in length by 80 in breadth, the upper copper-bearing series obtains the greatest development. Distinct belts of rock extend from thence along the line of the lake coasts by Thunder Bay to Font du Lac; and in one of those, styled the Lake Shebandowan band, the gold-bearing rock is found. Gold-bearing veins are also reported to occur at Cross Lake on the Red River route; and far beyond the province of Manitoba, a rich copper region has long been known on the Mackenzie River.

As railways are extended, and the great project of a Canadian line from the St Lawrence to the Pacific is gradually made an accomplished fact, the resources of the regions traversed by it will be fully disclosed and turned to account. The vicinity of the great coal-fields of Pennsylvania and Michigan to Lake Erie and Lake Huron, must always give them an advantage in any competition for the supply of Ontario with fuel. But the development of the railway system of the Dominion cannot fail to render its own mineral resources available to a much larger extent, not only for home consumption but for exportation. The Intercolonial Railway has opened up an extensive country to the coal miners of Nova Scotia; and the like results will follow both in the north-west and in British Columbia, when the great coal-fields of those regions are traversed by roads and railways, and their fertile prairies and rich alluvial valleys are settled by an industrious population. At present Canada both exports and imports coal, though

the imports as yet greatly exceed the exports. The total produce of the mines of Canada, including coal, exported during the fiscal year 1874 amounted in value to $3,977,216. The following tabular statement shows the present resources of the Dominion, and its dependence on external sources for its supply of coal:—

Canadian Export and Import of Coal for 1874.

	Export in Tons.	Import in Tons.
Nova Scotia	360,184	67,349
New Brunswick	6,627	142,503
Prince Edward Island	219	696

Trade of Canada.—The abstract of the value of the growth, produce, and manufactures of Canada, as shown by its exports, is classed in the official returns under six principal heads, viz., the mines, the fisheries, the forest, animals and their produce, agricultural products, and manufactures. The results show, by a comparison with the earlier statistics of the country, the rapid progress it has made in a single generation.

The trade of Canada at a period not very distant was confined chiefly to the exportation of furs, seal-oil, and timber, little exceeding £100,000 annually. Prior to the year 1759, when the country, with its population of 65,000 inhabitants, was transferred from the Government of France to that of England, the amount of its annual exports was £115,415. The principal trade was furs, in pursuit of which the great forests were traversed by bands of resolute adventurers. A few ships were occasionally built. Agriculture was neglected, if not actually despised.

Upon the acquisition of the country, however, by England, the cultivation of the soil attracted the attention of the settlers, and the germs of a trade sprung up which has now grown to be one of real magnitude and importance. In 1769 the exports in furs, oil, fish, &c., amounted to £355,000, and the imports in British manufactured goods and West India produce, reached £273,400. This trade employed seventy vessels; about twelve vessels were at the same period engaged in the fisheries of the St Lawrence, and about six were sent to the West Indies.

In 1799 and the three following years we find comparatively large exportation of grain taking place. In 1802, 1,010,000 bushels of wheat, 38,000 barrels of flour, and 32,000 cwts. of biscuit were sent abroad. The number of vessels at this period engaged in the trade of the colony was 211, the aggregate burden of which amounted to 36,000 tons. In 1809 the first steamboat appeared in the harbour of Quebec.

In 1809, 1810, and 1812, the trade of Canada, benefiting by increased duties levied upon Baltic timber imported into Britain, seems to have been comparatively active. In the first of these years 440 vessels, having an aggregate tonnage of 87,825 tons, arrived at Quebec. In 1810 as many as 635 vessels arrived in the St Lawrence, with an aggregate tonnage of 138,057 tons; and in the same year 26 vessels, having a tonnage of 5836 tons, were built in the province. In 1812, 532 vessels, with a tonnage of 116.687 tons, cleared at the port, 37 of which had been built at Quebec.

The war which commenced in 1812 between the United States and Britain severely checked the commerce of the St Lawrence, which was greatly dependent upon the Americans. And, notwithstanding that Britain slightly relieved the import duties on wheat in favour of Canada in 1814, we find that the trade of the colony from 1810 to 1820 remained almost stationary. The aggregate tonnage which arrived at Quebec in 1820 (a more prosperous year, if shipping be taken as the criterion, than any of the preceeding ten) amounted only to 9697 tons over that of 1810. In 1810, 26 vessels had been built in the colony, and only 7 were built in 1820.

According to the old system of colonial monopoly, the St Lawrence was rigidly closed against the entrance of foreign vessels, nor was any Canadian vessel allowed to enter a foreign port. The prosperity of the colony during this period of its infancy was believed not to have been materially checked by these restrictions, as the mother country at all times afforded an outlet for its surplus produce. After the United States had achieved their independence, their vessels were excluded from the ports of the British colonies; and Canada, as a reward for its loyalty, received the exclusive privilege of supplying the West India Islands with timber and provisions.

In this manner, as the trade of Canada had been confined and shackled for the supposed benefit of the mother country, so now she was rewarded with compensating privileges to the direct injury of the sister colonies of the West Indies. The United States ports were the natural resorts of the West Indies for timber and provisions, their distance from these being about one-half less than the ports of the St Lawrence. But the additional freight, which on such bulky articles constitutes a great proportion of the expense, was not only enhanced by this circuitous route, but the West Indies had to pay besides for transshipment upon what was supplied by the United States to Canada for the West Indian market. The West India planters were thus laid under contribution for the support of the Canadian shippers and farmers.

These regulations were, however, so far relaxed in favour of the West Indies in 1822, that the wheat and lumber of the United States were allowed to be imported directly on payment of certain duties; but at the same time duties were imposed upon agricultural produce entering the British American colonies as well as the West Indies.

The immediate result of this measure, so far as it affected Canada, was that one-half of the export trade of the St Lawrence was at once destroyed. The simultaneous abundance of the English harvest, together with the restrictions then in force upon the importation of grain into Britain, even from her own colonies, forbade any exports thither, and thus seriously aggravated the depression of Canadian commerce, and afforded another illustration of the ruinous policy of bolstering up one class by privileges and exemptions, and shackling another by restrictions and duties.

In 1825 Britain admitted Canadian flour and wheat into her ports at a fixed duty of 5s. sterling per quarter. Meanwhile a fresh trouble had already arisen to try the vexed fortunes of Canada. Previous to 1822, American exports had to a considerable extent sought the route of the St Lawrence, as if they had been of Canadian origin, contributing very materially, of course, to the benefit of the trade of the colony. But the opening of the Erie and Champlain canals in the United States, in 1825, drew off into a different channel those American exports which had formerly sought the Atlantic by way of Quebec, and the trade of the St Lawrence was thus seriously injured.

In 1826, however, the prospects again appeared to be brightening. The Americans were allowed, after four years of exclusion, to export timber and ashes for the British market into Canada free of duty. The duty upon Canadian flour for the West India market was also reduced.

The trade of the colony likewise profited by the disputes between Britain and the United States, which led to the

interdiction of the American export trade to the West Indies. This was reduced from £500,000 in 1826 to less than £500 in 1830. While the results were such to the United States, we find the trade of the St Lawrence in 1830 not only fairly recovered from the effects of the Imperial Acts of 1822, but far surpassing its position at any former period. The arrivals at Quebec in 1830 were 967 vessels, having a tonnage of 238,153 tons.

In 1831 the trade of the colony was still further favoured by the action of the Home Government. The forest and agricultural products of the United States were admitted into Canada free of duty, and could be exported by the St Lawrence, as Canadian produce, to all countries except the United Kingdom. A differential duty was also at the same time imposed upon foreign timber entering the West Indian and South American possessions, greatly to the benefit of the colony, which also profited by the scarcity of food existing in Britain at this time. The arrivals at Quebec during this favoured and prosperous year, were 1016 vessels, with a tonnage of 261,218 tons; and the exports of flour and wheat by the St Lawrence were about 400,000 barrels, chiefly to Britain.

Between 1831 and 1836 we find a complete reversal of the order of trade between the colony and the mother country. The crops in England during that period being unusually abundant, and a scarcity of bread-stuffs existing in the United States, wheat was, in 1833, shipped from Britain to Quebec. A supply also came from Archangel. These imports from Europe to the St Lawrence amounted in 1835 and 1836 to about 800,000 bushels. The relaxation by the mother country of her protective policy in 1842 was viewed with alarm by the colonists as fraught with disastrous consequences to their interests. Up to 1842 Baltic timber had paid an English import duty of 55s. per load, while Canadian timber entered England upon payment of 10s. per load. The duty on foreign timber was now reduced to 30s. and Canadian to 1s. per load. At the same time the free importation of United States flour into the colony was stopped, and the West Indies were allowed, on the payment of a duty of 2s. per barrel, to import their flour direct from the Americans.

These serious blows to the trade of the St Lawrence fell upon the colony at the period of a commercial crisis, and were therefore felt more severely. The number of vessels that entered the St Lawrence in 1842, from the sea, was 377 less than during the previous year.

In 1843, Canada was allowed to import American wheat under a comparatively nominal duty, and to export it through the St Lawrence as native produce to the British market. This measure, which may be viewed as having been the first indirect blow at the English corn-laws, amounted to a virtual premium of about 6s. sterling per quarter upon American exports to Britain through the St Lawrence. The British ports were thus at once in a great measure thrown open to all the great wheat-growing countries of North America. Canadian exports were rapidly swelled in consequence; and in 1846 half a million of barrels, and as many bushels of wheat and flour, were shipped by the St Lawrence. The timber trade of the colony, which was also seriously threatened in 1842 by the large reduction of the duty on Baltic timber imported into England, witnessed likewise in 1845 and 1846, not merely a revival, but a very material increase. The number of vessels that entered the St Lawrence rose to 1699 during each of these years, with an aggregate burden of over 620,000 tons,—this being a much larger amount of shipping than had ever in any previous year entered the St Lawrence.

The history of Canadian trade enters upon a new stage from 1846, when the commercial policy of England at length relaxed the old restrictive navigation laws in reference to her colonial possessions. One of the most practical evidences of its beneficial influence on Canadian trade is shown in the increase of its traffic with the United States, at the very time that its trade relations with the mother country were being annually augmented in a corresponding ratio. From 1821 to 1832, the aggregate annual traffic between the United States and Canada averaged no more than $3,257,153. From 1833 to 1845 the average increased, with the growing population, industry, and wealth of both countries, to $6,313,780 per annum. But under the influence of the more liberal policy inaugurated by Great Britain in 1846, the traffic rose between that year and 1853 so rapidly that its annual average amounted to $14,230,763.

But the concessions made by the mother country in favour of the timber and corn trade of Canada were still only partial. The exportation of colonial produce from the St Lawrence could only be carried on in British vessels; and thus there grew up a class of vessels specially appropriated to this trade, which made only two voyages in the year to Quebec or Montreal; and these having a monopoly of the whole exports of the St Lawrence at privileged rates, the colony was virtually subjected to a heavy tax both on its exports and imports. Tea, coffee, sugar, and all the manufactured articles still required to be obtained from abroad were thus only obtainable through English ships; and hence the Canadian merchant was greatly restricted in the choice of the best and cheapest market. In return, however, the colonists had certain privileges accorded to them, foremost amongst which were those already referred to in connection with the import of wheat from the United States, and its export from the St Lawrence as native produce,—the Canadian merchants having an advantage thereby over their competitors in New York and other American ports.

The abolition of the British corn laws deprived Canada of the privileges thus accorded to her in the export of bread-stuffs, and seemed to threaten the trade of the St Lawrence with grievous discouragement at the very time when the transactions of the colony with the United States were in a great measure interdicted by a hostile tariff. The changed and more enlightened views, however, which entered into imperial legislation materially assisted the growing energies and intelligence of the colonists. The Imperial Government formally abandoned in 1847 all control over the customs of the colony, which immediately set itself to the task of regulating its own trade. One of the first measures of the colonial legislature was to abolish in a great degree the differential and prohibitory duties on colonial imports along the United States frontier; and the Americans upon the other side of the St Lawrence were by this measure placed, as regards matters of trade, upon an equal footing with England. The beneficial effects of this measure showed itself at once in increased commercial activity and prosperity over the whole of Canada.

On the 1st of January 1850, England completed her free trade measures by relieving the colonies from the injurious effects of the British navigation laws. The value of the more enlightened views which thus entered into both imperial and colonial legislation has since been most satisfactorily tested in the growing wealth and prosperity which have attended the progress of the colony. The same year is memorable for other events affecting Canadian progress. It was in 1850 that gold was first discovered in British Columbia, and coal at Nanaimo, on Vancouver Island; and so the steps were accelerated which led to the organization of the first province of the Dominion on the Pacific. The same year was marked by the organization of the opposition to ecclesiastical endowments, as well as to

other exclusive rights and privileges, which resulted in 1854 in the final settlement of the vexed questions of the clergy reserves and seigniorial tenures in Upper and Lower Canada. The Grand Trunk Railway, which had been commenced in 1847, was now hastening to completion. Nova Scotia had already its first railway; the important local line connecting the Georgian Bay with Toronto, was developing the resources of Upper Canada; and in the same year, 1854, the Great Western Railway was commenced. By this line Toronto is not only placed in direct communication with Detroit, Chicago, and the whole Western United States; but by the extension of the line from Hamilton to the vicinity of the Niagara Falls, and the construction there of a suspension bridge, on a grand scale, for railway as well as ordinary traffic, the Great Western Railway of Canada has become an important link in the main lines of transit from Boston and New York to the Western States. Since then the building of railways and the development of railway traffic have been energetically prosecuted. The Intercolonial Railway has been completed, as a material bond of union between the older provinces of Canada and the maritime provinces, and a route through Canadian territory, at all seasons, to the seaboard. This has been followed by the more comprehensive scheme of a Canadian Pacific Railway, the surveys for which have been already made; and its first links are now in process of execution. The actual mileage of the railways within the Dominion completed, up to the close of 1874, extended to 4022 miles. The following tabular view of the railway traffic returns for the two previous years will suffice to illustrate their influence on the rapid growth of Canada in recent years:—

Railways.

Railways.	Total 1873.	Total 1872.	Miles 1873.	Miles 1872.

[1] 8 months. [2] 10 months. [3] 1 month. [4] 5 months. [5] 5 months.

Telegraphs.

During the same period telegraphic lines of communication have been no less energetically prosecuted. At the end of 1874 the Montreal Telegraph Company had 23,267 miles of wire, and 1288 different offices; and to both additions are being rapidly made. The Dominion Telegraph Company, more recently organized, with its head-office in Toronto, had at the same date 6000 miles of wire, connecting 300 different offices; and the British Columbia Telegraph, which was assumed by the Dominion Government, at the admission of British Columbia into the confederation, had already placed the head office at Victoria in communication with twenty-one offices, the remotest of which was then distant 557 miles.

Banks.

No less important is the banking system of the Dominion. From the banking returns published in the *Canada Gazette* it appears that the banking capital has more than doubled since 1870, and this by a steadily progressive increase. The tables are imperfect, owing to some of the banks having omitted to make the requisite returns; so that, while the following tabular statement illustrates the progressive rate of increase, it falls short of the full amount:—

Banking Capital of Canada.

1870....................	$29,801,013
1871....................	36,415,390
1872....................	45,134,609
1873....................	55,102,959
1874....................	60,443,445

Besides the Post-Office Savings Banks, established on the same principle as those in Great Britain, there are local and other savings banks, building and other societies,—and the admission of every new province adds to the number of such societies,—in all of which large amounts are deposited at interest, without accessible returns. The building societies advance funds for the erection of churches, halls, and other public buildings, as well as for private dwelling-houses; and the majority of the residents in cities and towns are proprietors of the houses which they occupy. The following tabular statement affords an illustrative view of the accumulating fruits of industry within the Dominion.

Bank Deposits.

Post-Office Savings' Banks..................	$3,587,365
Government Savings' Banks	3,862,676
Montreal City and District Banks	4,303,509
Caisse d'Economie de Notre Dame........	2,732,055
Chartered Banks..............................	78,790,367
Total..................	$93,275,972

Summary.—The evidence of the prosperity, and growing wealth of Canada may be completed in a tabular view of its exports and imports for two successive years, as derived from the latest official returns. The immediate result of confederation was a rapid progress in many ways. New railways were projected and brought into operation; new lines of steamships were established; fresh avenues of native and foreign trade were diligently sought out; and a succession of prosperous years was marked by a steady commercial expansion which attained its maximum in 1873. Since that date various causes, and especially the difficulties created by an unredeemable paper currency in the neighbouring United States, have tended to bring about a reaction; but it is a mere temporary ebb of the advancing tide, in which the commercial world at large has shared.

The following is a reproduction of a condensed comparative statement of the Commissioner of Customs, as given in the trade and navigation tables for 1874; to which are added from more recent unpublished returns, those of the year 1875, showing the influence of a period of reaction and great depression, alike on the exports and imports of the country.

Fiscal Year.	Total Exports	Total Imports	Entered for Consumption.	Duty.
1868........	[illegible]	[illegible]	[illegible]	[illegible]
1869........	[illegible]	70,415,165	[illegible]	[illegible]
1870........	[illegible]	[illegible]	[illegible]	[illegible]
1871........	74,173,618	[illegible]	[illegible]	[illegible]
1872........	[illegible]	[illegible]	[illegible]	[illegible]
1873........	[illegible]	[illegible]	[illegible]	[illegible]
1874........	[illegible]	[illegible]	[illegible]	[illegible]
1875........	[illegible]	[illegible]	[illegible]	[illegible]
Aggregate (of Eight Years)	[illegible]	[illegible]	[illegible]	[illegible]

The apparent annual increase shown in the above table, is modified by the following elements, which must be taken into account. The first three years represent the business only of the first four provinces of the Dominion. Manitoba was received into the confederacy in 1871; and the

statistics of that year include six months' returns from the new province, amounting to $254,063 total imports, $286,337 entered for consumption, and $15,723·22 duty collected. In 1872 the exports of Manitoba were valued at $85,541, the imports at $942,247, and entered for consumption, $1,020,172, on which $46,839·90 duty was collected. In the same year the returns for British Columbia appear as follows:—exports, $1,912,107; imports, $1,790,352; entered for consumption, $1,767,068; duty collected, $342,400·48. In 1874 the returns of Prince Edward Island give the following additional elements to swell the aggregate amount:—exports $722,129; imports, $1,908,522; entered for consumption, $1,913,696; duty collected $219,458·07. Deducting those sums and values from the years named, there remains abundant evidence of a steady and rapid increase in the commerce of the four older provinces up to the year 1874, when the depression prevailing in the United States, in part due to reaction resulting from the effects of the southern war, began to be felt in Canada as well as in other countries. The great expansion which has taken place in the commerce of Canada since 1867, and the influence of the reaction of 1874, are shown in the following consecutive statement of the joint value of exports and imports for the years from 1868 to 1875 inclusive:—

Exports and Imports.

1867–68	$131,027,532
1868–69	130,889,946
1869–70	148,387,829
1870–71	170,266,589
1871–72	194,070,190
1872–73	217,801,203
1873–74	217,565,510
1874–75	201,116,963

The relative wealth and progress of the different provinces of the Dominion will be illustrated by the following comparative table, showing the last year of nearly unchecked progress, and the first of reaction. It shows the value of the goods exported from, and entered for consumption in the Dominion, during the years ending the 30th June 1874 and 1875:—

Province	Year 1873–4.			Year 1874–5.		
	Exports. Value.	Entered for Consumption.		Exports. Value.	Entered for Consumption.	
		Value.	Duty.		Value.	Duty.
Nova Scotia	$7,656,547	$10,875,140	$1,409,094	$6,968,139	$10,688,213	$1,490,548·77
New Brunswick	6,503,934	10,321,492	1,399,930·75	6,542,829	9,855,533	1,370,611·42
Prince Edward Island	722,129	1,913,696	219,458·07	1,307,590	1,984,278	316,976·49
Quebec	46,393,845	51,981,127	6,613,509·50	39,801,041	50,618,588	6,772,303·90
Ontario	25,157,087	48,375,522	4,361,236·06	20,016,101	42,781,076	4,808,074
Manitoba	794,762	1,853,659	67,471·97	588,958	1,227,890	171,430·86
British Columbia	2,120,624	2,048,336	336,494·47	2,824,712	2,487,293	413,991·50
Total	$89,351,928	$127,368,972	$14,407,194·82	$78,048,870	$119,622,871	$15,343,931·94
Export Duty	...	...	14,564.90	...	...	7,231·86
			$14,421,759·72			$15,351,163·80

Administration of Justice.—So long as Canada consisted of the two provinces of Upper and Lower Canada, even when united for legislative purposes they retained their diverse laws and distinct judicial systems, while the Privy Council of Great Britain constituted the final court of appeal for both. In the province of Quebec the old French law, which was introduced under Louis XIV., is still the basis of the law of property. There the tenure of property remained strictly feudal, until the settlement of the claims of the seigniories by the Act of 1854 brought the old system to an end. But before that was effected new townships had been surveyed, and land disposed of to settlers to be held in free and common soccage. The commercial law is regulated partly by the old French code, but modified by the English customs, and by later Canadian legislation. The criminal laws of England, and the right of trial by jury, were introduced by 14th Geo. III c. 83. Since then all additions to the criminal law, or modifications of the statutes, have depended on the Acts of the colonial legislature. The religion, laws, language, and customs of the French population were all guaranteed to them at the time of the cession of Canada to England; and the rights and privileges pertaining to the Roman Catholic Church, among a population regarding its creed as their national religion, help to perpetuate essential differences, by maintaining what is still practically an established if not a state church.

By the constitution of the Dominion, as embodied in the British North American Act of 1867, the criminal law, with the establishment, maintenance, and management of penitentiaries; all laws relating to bankruptcy and solvency, marriage and divorce, naturalization, aliens, Indians, and Indian reserves; and generally, all subjects not expressly assigned to the provincial legislatures, pertain to the Dominion parliament. The judges in all the provinces are appointed by the general Government; and the pardoning power is vested in the governor-general *per se*, whilst his authority in all other respects is exercised under the advice of his privy council, or ministers for the time being. The powers entrusted to the local legislatures include generally all strictly local legislation not affecting in any way the rights of other provinces. The judges by whom the laws are administered must in the case of Quebec be selected from the bar of that province; and the judges of the superior courts in all the provinces hold office during good behaviour, and are removable by the governor-general on address of both houses of Parliament.

The rights and privileges of each province being thus secured by its own parliament and courts of law, the provisions of the Act of Confederation have been completed by the establishment of a Supreme Court and Court of Exchequer at Ottawa, consisting of a chief justice and five other judges, two of whom, including the chief justice, have been selected from the bench of Ontario, two from the bench and bar of Quebec, and one each from the bench or bar of Nova Scotia and New Brunswick. The court thus constituted is the supreme and final court of appeal, from all the courts of law in the various provinces,—with this exception that, while no appeal lies from the Supreme Court at Ottawa to the Privy Council, litigants have still the right of choice between the two as their final court of appeal.

Education.—Almost from the first organization of Upper Canada as a separate province, steps were taken for providing means for the establishment of efficient schools and colleges. So early as 1797 a grant of 500,000 acres of the unoccupied lands of the province was set apart for the purpose of establishing and endowing a university and four royal foundation grammar schools. Of this one half was appropriated as a university endowment, and one-fourth

of the remainder was granted to Upper Canada College, which assumed in Canada the functions of the great public schools of England, and still continues to hold its place at the head of the grammar or high schools of the province.

In the earlier years of Upper Canada, the "Clergy Reserves," set apart originally for the support of a "Protestant" clergy, were appropriated exclusively by the ministers of the Church of England. Upper Canada became an archdeaconry of the diocese of Quebec; and the venerable Archdeacon Strachan, whose first labours in Canada had been as master of the Cornwall Grammar School, became the leader both in ecclesiastical and educational matters, and ultimately a privy councillor, member of the legislative council, and bishop of the diocese of Toronto. He was a man of great energy and decision of character; and under his guidance the lands set apart for the endowment of a provincial university were appropriated to the purpose, and a royal charter was granted by George IV. establishing at Toronto, or York, as it was then called, "one college, with the style and privileges of an university, for the education and instruction of youth and students in arts and faculties," under the name of King's College. The bishop of the diocese became, *ex officio*, visitor; and when at length the college was organized, it had its divinity faculty, and its professor of divinity, along with its daily religious services according to the use of the Church of England. The special denominational character thus given to the provincial university excited opposition, and led to the establishment of Queen's College, at Kingston, under the control of the Church of Scotland, and of Victoria College, Cobourg, under the Wesleyan Methodist Church. To those have since been added Albert College, Belleville, under the management of the Episcopal Methodist Church; and Ottawa College, and Regiopolis College, Kingston, in connection with the Church of Rome. All of those possess university powers, either by Royal Charter, or by Acts of the provincial legislature. By subsequent enactments the constitution of King's College has been greatly modified. Its divinity faculty has been abolished, all denominational restrictions have been removed, and its functions divided between a university proper, modelled after the university of London, with a senate, on which devolves the fixing of the requirements for degrees, the appointment of examiners, and all other university work, as distinct from teaching. The latter is under the conduct and regulation of the professors, who constitute the council, of University College, and undertake all the duties of preparing the under-graduates for the university examinations in arts and science. Other colleges and schools, both in the faculty of arts and in those of law and medicine, are affiliated to the university, and part of the funds at the command of the senate is appropriated for scholarships, to be competed for at the examinations in the different faculties. On the passing of the Act of 1853, by which the divinity faculty and professorship were abolished, a royal charter was obtained for the establishment of Trinity College, in connection with the Church of England, with all the powers of a university

The system of public instruction for Ontario has hitherto been carried out under the direction of a permanent officer, styled the Chief Superintendent of Education, with the advice of the Council of Public Instruction, originally nominated by the Crown, but latterly including representatives of the universities, of the school inspectors, and the masters of high and public schools. But by a recent Act of the Ontario Legislature, the functions of the Council of Public Instruction have been transferred to a committee of the executive council; and the functions and duties of the chief superintendent are vested in one of its members, to be designated the Minister of Education. The introduction of the representative element into the Council of Public Instruction was immediately followed by a conflict between that body and the officers of the department in reference to various proposed modifications; and the changes now introduced aim at bringing the administration of the system of education more directly under the control of the people through their representatives.

There are two normal schools for the training of teachers, one at Toronto, and one at Ottawa; and it is proposed to establish others at Kingston and London. The high schools are divided into (1) collegiate institutes and (2) high schools for teaching classical and English subjects, and (3) high schools, in which instruction may be limited chiefly to English subjects. Of those there were 108 in all, including 8 collegiate institutes, in 1875, with an attendance of 8437 pupils.

The primary schools for junior pupils are styled public schools. The school population, including those between 5 and 16 years of age, was returned in 1874 as numbering 504,869. At the same date there were 4732 schools in full operation, with an attendance of 460,984 pupils. In all the above schools every feature of a denominational character is excluded. The collegiate institutes and high schools are under the control of trustees appointed by the county municipalities, and their maintenance depends on their share of the legislative grant and endowments, supplemented by the annual assessments of the city and county municipalities. The public schools are in like manner supported by legislative grants, and by assessments levied on the requisition of the school trustees in each school section. The essential feature of the whole system is that the people, directly or through their representatives, have the entire control of the schools, including the selection of the teachers, the fixing of their salaries, and the management of the school funds.

The one exceptional feature is the Roman Catholic separate schools. Any Roman Catholic can require his school-tax to be paid for the maintenance of the separate schools of his own church; and with this fund, supplemented from other sources, there were, in 1875, 170 separate schools in Ontario, with an average attendance of 11,123 pupils, or of 22,073 on the school rolls. According to the proportion of the Roman Catholic population, this is less than a third of their children of school age. A large proportion of the remainder attend the public schools. Masters of high schools are required to be graduates of universities, and to have had previous experience in teaching. Teachers of public schools must hold a normal school or other recognized certificate of qualification.

The principal features of the system of education thus brought into efficient operation have been modelled on those of the states of New York and Massachusetts, and on the normal schools of the Irish National Board of Education. The systems of the other Canadian provinces, with the exception of Quebec, have been framed on this model. In the last-named province, where the great mass of the people are Roman Catholics, the education is in the hands of the clergy, and is avowedly carried on in connection with the Church of Rome. But dissentient or Protestant schools are recognized as a part of the public school system, and the permanency of this state of things is guaranteed by a clause in the Act of Confederation, which excludes it from the interference of the general legislature.

General Remarks.—The position which Canada now occupies as a Dominion formed by a confederation of self-governing provinces, united under a central Government, with its own governor-general, cabinet ministers, senate, parliament, and supreme courts of law,—yet nevertheless remaining an integral part of the British Empire, and

acknowledging the sovereignty of its Queen,—is unique in the history of nations, and strikingly illustrates the adaptability of British institutions to the novel requirements of a free people. The peculiar circumstances resulting from the union of a colony formed under the fostering restraints of French ecclesiastical and civil rule with one of purely English origin, and settled in part by loyalist emigrants from the United States, begot difficulties which were more and more felt as the mother country removed from Canada one after another of the restrictions on self-government. It will form an interesting chapter in the history of Britain in relation to her colonies, to note the freedom with which, when those of British North America had, as it were, attained their majority, they were left to frame a scheme of confederation suited to their circumstances; and when, after free deliberation, it had been matured to the satisfaction of those most directly interested in the results, the Imperial Government received it at their hands, and the British Parliament gave it the force of law. At the very period when this novel experiment in the history of colonization had been carried out to completion, and was open to the test of experience, the vice-regal duties were entrusted to the earl of Dufferin as governor-general of Canada. In the exercise of his duties he has visited many portions of the Dominion; and towards the close of an extensive tour in the summer of 1874, he thus gave expression to the results of his observations:—"Everywhere I have learnt that the people are satisfied,—satisfied with their own individual prospects, and with the prospects of their country; satisfied with their Government, and the institutions under which they prosper; satisfied to be the subjects of the Queen; satisfied to be members of the British Empire. Indeed, I cannot help thinking that, quite apart from the advantage to myself, my early journeys through the provinces will have been of public benefit, as exemplifying with what spontaneous, unconcerted unanimity of language, the entire Dominion has declared its faith in itself, in its destiny, in its connection with the mother country, and in the well-ordered freedom of a constitutional monarchy. It is this very combination of sentiments, which appears to me so wholesome and satisfactory. Words cannot express what pride I feel as an Englishman in the loyalty of Canada to England. Nevertheless I should be the first to deplore this feeling, if it rendered Canada disloyal to herself,—if it either dwarfed or smothered Canadian patriotism, or generated a sickly spirit of dependence. Such, however, is far from being the case. The legislation of the Parliament of Canada, the attitude of its statesmen, the language of its press, sufficiently show how firmly and intelligently its people are prepared to accept and apply the almost unlimited legislative faculties with which it has been endowed; while the daily growing disposition to extinguish sectional jealousies, and to ignore an obsolete provincialism, proves how strongly the young heart of the confederated commonwealth has begun to throb with the consciousness of its national existence. At this moment not a shilling of British money finds its way to Canada; the interference of the Home Government with the domestic affairs of the Dominion has ceased; while the imperial relations between the two countries are regulated by a spirit of such mutual deference, forbearance, and moderation, as reflects the greatest credit upon the statesmen of both. Yet so far from this gift of autonomy having brought about any divergence of aim or aspiration on either side, every reader of our annals must be aware that the sentiments of Canada towards Great Britain are infinitely more friendly now than in those early days when the political intercourse of the two countries was disturbed and complicated by an excessive and untoward tutelage; that never was Canada more united than at present in sympathy of purpose, and unity of interest with the mother country, more at one with her in social habits and tone of thought, more proud of her claim to share in the heritage of England's past, more ready to accept whatever obligations may be imposed upon her by her partnership in the future fortunes of the empire." (D. W.)

CANAL

NAVIGABLE canals may perhaps be most conveniently treated under two classes, *Barge* or *Boat* Canals, now in many cases almost superseded by railways and *Ship* Canals, which, judging from the stupendous works of this class recently executed and now in contemplation, seem as yet far from having exhausted the important aids they are destined to afford to navigation.

After giving a historical notice of early canals, the following article contains a brief notice of Barge Canals; a digest of general engineering principles applicable to the construction of all canals; an account of Ship Canals recently constructed; and a notice of Ship Canals which have been proposed and are ere long likely to be carried into execution for facilitating ocean navigation.

rly his- y.

From the writings of Herodotus, Aristotle, Pliny, and other ancient historians, we learn that canals existed in Egypt before the Christian era; and there is reason to believe that at the same early period artificial inland navigation also existed in China. Almost nothing, however, save their existence has been recorded with reference to these very early works; but soon after the commencement of the Christian era canals were introduced and gradually extended throughout Europe, particularly in Greece, Italy, Spain, Russia, Sweden, Holland, and France.

In speaking, however, of the earliest of these works, it is not to be supposed that they resembled the modern canals now constructed in our own and other countries. Early as inland navigation was introduced, it was not until the invention of canal-locks, by which boats could be transferred from one level to another, that inland navigation became generally applicable and useful, and it has been truly remarked "that to us, living in an age of steam-engines and daguerreotypes, it might appear strange that an invention so simple in itself as the canal-lock, and founded on properties of fluids little recondite, should have escaped the acuteness of Egypt, Greece, and Rome."[1] Not only, however, had the invention escaped the notice of the ancients, but what is more striking, the several gradations made towards the attainment of that simple but valuable improvement appear to have been so gradual that, like many discoveries of importance, great doubts exist as to the *person* and even the *nation* that was the first to introduce canal-locks. One class of writers attributes the discovery to the Dutch, and Messrs Telford and Nimmo, who wrote the article "Inland Navigation" in Brewster's *Edinburgh Encyclopædia*, adopt the conclusion that locks were used in Holland nearly a century before their application in Italy; while, on the other hand, the invention has been strongly and not unreasonably claimed for engineers of the Italian school, and in particular for Leonardo da Vinci, the celebrated engineer and painter.[2] Without, however, entering into a discussion of this question, which it is now perhaps impossible to solve, we may safely state that during

[1] *Quarterly Review*, No. cxlvi. p 281

[2] Frisi *On Canals*, p. 154.

the 14th century the introduction of locks, whether of Dutch or Italian origin, gave a new character to inland navigation, and laid the basis of its rapid and successful extension. And here it may be proper to remark, that the early canals of China and Egypt, although destitute of locks, do not appear to have been on that account formed on a uniformly level line, unadapted to varying heights. It is very doubtful, indeed, if the use of locks has even yet been introduced into China, intersected as it is by many canals of great antiquity and extent, the imperial canal being about 1000 miles in length. "This canal appears to have been completed in 1289, and is said to extend for a distance of forty days' navigation, and is provided with many sluices, and when vessels arrive at these sluices they are hoisted by means of machinery, whatever be their size, and let down on the other side into the water."[1] Nevertheless the invention of locks was, as has been stated, a most important step in the history of canals; and that mode of surmounting elevations may be said to be almost universally adopted throughout Europe and America. Inclined planes and perpendicular lifts have, it is true, been employed in those countries, as will be noticed hereafter; but the instances of their application are undoubtedly rare.

Languedoc Canal.

But without tracing the gradual introduction of canals from country to country, we remark at once that we find the French at the end of the 17th century, in the reign of Louis XIV., forming the Languedoc Canal, designed by Riquet, between the Bay of Biscay and the Mediterranean, a gigantic work, which was finished in 1681. It is 148 miles in length, and the summit level is 600 feet above the sea, while the works on its line embrace upwards of one hundred locks and fifty aqueducts, an undertaking which is a lasting monument of the skill and enterprize of its projectors; and with this work as a model it seems strange that Britain should not, till nearly a century after its execution, have been engaged in vigorously following so laudable an example. This seems the more extraordinary, as the Romans in early times had executed works in England, which, whatever might have been their original use, whether for the purposes of navigation or drainage, were ultimately, and that even at an early period, converted into navigable canals. Of these works we particularly specify the Caer Dyke and Foss Dyke cuts in Lincolnshire, which are by general consent admitted to have been of Roman origin. The former extends from Peterborough to the River Witham near the city of Lincoln, a distance of about 40 miles; and the latter extends from Lincoln to the River Trent, near Torksey, a distance of 11 miles.

Foss Dyke.

Of the Caer Dyke the name only now remains; but the Foss Dyke, though of Roman origin, still exists, and as it is the oldest British canal, the reader may be interested to learn the following facts as to its history. Camden in his *Britannia* states that the Foss Dyke was a cut originally made by the Romans, probably for water supply or drainage, and that it was deepened and rendered in some measure navigable in the year 1121 by Henry I. In 1762 it was reported on by Smeaton and Grundy, who found the depth at that time to be about 2 feet 8 inches.[2] They, however, discouraged the idea of deepening by excavation. They say they found "the bottom to be either a rotten peat earth, or else a running sand," and that though the deepening of the navigation is in "nature possible," yet it "cannot be effected without removing one of the banks in order to widen the same," which would not only turn out expensive, but would "occasion much loss of time and profit to the proprietor while the work is executing." Nothing followed on this report; but in 1782 Smeaton was again called in, and deepened the navigation to 3 feet 6 inches, not, however, by widening the canal or dredging, but by raising the water-level 10 inches.[3] From that period nothing more was done to enlarge the water-way, or adapt it to increased traffic. Meantime the adjoining Witham navigation having been improved, the defects of old Foss became more apparent, and in 1838 Mr Vignoles was consulted, and made an elaborate report on alternative schemes for increasing the depth to 4 and 6 feet: nothing, however, was done till 1840, when Messrs Stevenson were employed to design works for assimilating the Foss Dyke as far as practicable, both as regards width and depth, to the navigable channel of the Witham. The depth was found to be 3 feet 10 inches, and its breadth in many places was insufficient to admit of two boats passing each other, and for their convenience occasional passing places had been provided. It was resolved to increase the dimensions of the canal, and to repair the whole work. Accordingly it was widened to the *minimum* breadth of 45 feet, and deepened to the extent of 6 feet throughout. The entrance lock communicating with the River Trent at Torksey was renewed, and a pumping engine was erected for supplying water from the Trent during dry seasons, and thus that ancient canal, which is quoted by Telford and Nimmo as "*the oldest artificial canal in Britain*," was restored to a state of perfect efficiency, at a cost of £40,000, and now forms an important connecting link between the Trent and Witham navigations.

Bridgewater canals.

Notwithstanding the existence of this early work, however, and of some others in the country, particularly the Sankey Brook navigation, opened in 1760, it cannot be doubted that the formation of the Bridgewater Canal in Lancashire, the Act for which was obtained in 1759, was the commencement of British Barge Canal Navigation, of which we propose first to treat, and that Francis, duke of Bridgewater, and Brindley the engineer, who were its projectors, were the first to give a practical impulse to a class of works which, under the guidance mainly of Smeaton, Watt, Jessop, Nimmo, Rennie, and Telford, has been very generally adopted throughout the country, and has undoubtedly been of vast importance in promoting its commercial prosperity.[4]

According to Mr Smiles, the barge-canals laid out by Brindley, although not all executed by him, were:[5]—

feet above the river, the canal being carried across in a cast-iron trough.[1]

It must be obvious, that to construct a navigable channel through a country varying in level, and affording, perhaps, no great facilities for obtaining a supply of water, infers high engineering skill. Vast reservoirs must in some cases be formed for storing the water necessary to supply, during dry seasons, the loss by lockage, leakage, and evaporation. Feeders must be made to lead this water to the canal, hills must be pierced by tunnels, valleys must be crossed on lofty embankments, or spanned by spacious aqueducts, and, above all, the whole must be conceived and laid out with scrupulous regard to the all-important object of securing the works against injury from an overflow of water during floods, and a consequent inundation of the surrounding country. Moreover, the necessity of laying out the canal in level stretches, and surmounting elevations by means of locks or inclined planes, occurring at intervals, often occasions much difficulty and greatly restricts the resources of the engineer. Taking, then, all these circumstances into consideration, and bearing in mind that canals were the pioneers of railways, we think it may safely be affirmed that the canal engineers of former days had more serious *physical* difficulties to contend with than are experienced in carrying out the railways of modern times, if we except such works as the Britannia Bridge, the high-level bridge of Newcastle, the Boxhill tunnel, and some other kindred works. But, indeed, their *mechanical* difficulties were also greater, for the introduction of steam, and its wide-spread application to all engineering operations, afford facilities to the engineers of the present day which Smeaton at the Eddystone, Stevenson at the Bell Rock, and Rennie and Telford in their early navigation works, did not enjoy. The distinguished merits of the engineers who practised in the former and at the commencement of the present century, cannot indeed be over-estimated, and had it been within the scope of this article it would have been profitable and instructive to have described in detail some of the grand aqueducts and other works on the lines of our canals. For this reference is made to the articles Aqueduct, Bridge, Tunnel, and Reservoir, all of which are more or less applicable to the formation of canals. We shall only therefore offer to the student the following summary of engineering principles generally applicable to all cases.

A canal cannot be properly worked without a supply of water calculated to last over the driest season of the year, and in that respect, except as to the quality of the water, demands all the care requisite in investigating the sources of water for supplying towns. If there be no *natural* lake in the district, available for supply and storage, the engineer must select situations suitable for artificial reservoirs, and the conditions to be attended to in selecting their positions are the same as those for water-works. They must command a sufficient area of drainage to supply the loss by leakage, evaporation, and lockage, due to the length of canal, number and size of the locks, and probable amount of traffic. The capability of the district to afford this supply will depend on the area of the basin drained and the annual amount of rainfall. The offlets from the reservoirs must be at such an elevation as to convey water to the summit-level of the canal. The embankments for retaining the water must be erected on sites affording a favourable foundation, and, if possible, in situations where an embankment of small height and length may dam up a large amount of water. It is further necessary to consider whether the subsoil of the valley forming the reservoirs is throughout of so retentive a nature as to prevent leakage, and it is essential to provide, by means of waste weirs, for the discharge of floods. The Caledonian Canal, to be afterwards noticed, is in this respect very favourably situated, the whole supply being obtained from natural lochs. In other cases, such as the Union, Forth and Clyde, Crinan, Birmingham, and other canals, it was necessary to construct large reservoirs in which the water is stored in winter and led in feeders to points convenient for supplying the canal in summer. Where the canal communicates with the sea or a tidal river, and where the natural supply is small, as at the Foss Dyke already referred to, the water is raised by pumping engines. It will readily be seen, therefore, how important it is to reduce to a *minimum* the loss of water due to leakage from deficient workmanship, as well as to lockage of the traffic through the canal, and (while on this subject) it may be stated that the *up* consumes a greater amount of water than the *down* traffic, for an *ascending* boat on entering a lock displaces a volume of water equal to its submerged capacity; the water so displaced flows into the lower reach of the canal and the lower gates are closed, the boat is then raised, and on passing into the higher reach of the canal its displacement lost on entering is supplied by water withdrawn from the higher reach. A *descending* boat, on the other hand, on entering a lock likewise displaces a volume of water equal to its submerged capacity, but the water in this case flows back into the higher reach of the canal, where it is retained when the gates are closed. Mr Fulton gives the consumption of 25-ton boats through locks of 8 feet lift as about 163 tons of water in ascending, and 103 in descending.[2] Several proposals have been made for reducing the loss of water by side ponds to receive part of the water, but all such plans delay the traffic and have not come into general use.

Sectional areas of barge canals.

The barge-canals constructed in this country are between 4 and 5 feet in depth. When the soil in which they were made was retentive, they were formed, as shown in the cross-section, fig. 1. But when the soil was porous, clay

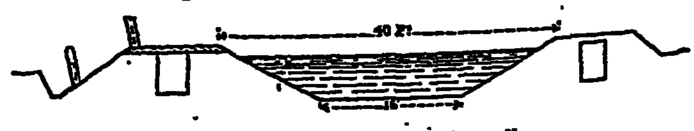

Fig. 1.—Section in retentive soil.

puddle was introduced, as shown in fig. 2. Professor Rankine says the depth of water and sectional area of water-way should be such as not to cause any material

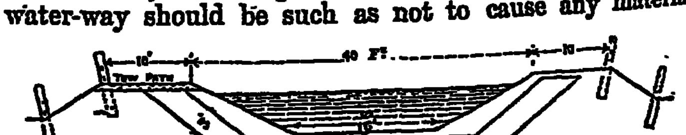

Fig. 2.—Section in porous soil.

increase of the resistance to the motion of the boats beyond what it would encounter in open water, and gives the following rules as fulfilling these conditions:—

Least breadth at bottom = 2 × greatest breadth of boat.
Least depth of water = $1\frac{1}{2}$ foot + greatest draught of boat.
Least area of water-way = 6 × greatest midship section of boat.

In laying out a line of canal the engineer is more restricted than in forming the route of a road or railway, where gradients can be introduced to suit the undulating surface of the country. A canal, on the contrary, must follow rigidly the bases of hills and windings of valleys, to preserve a uniform level, accommodation being made for the road traffic by erecting suitable "fixed" and "movable" bridges. It is important, as already stated, to lay out the work in long level reaches, and to overcome

[1] *Life of Telford*, London, 1838.

[2] Fulton's *Canal Navigation*.

elevations *in cumulo* by groups of locks at places where it can be most advantageously done. This leads to a saving of attendance and expense in working the canal, and causes fewer stoppages to the traffic. But to prevent waste of water the locks must be placed sufficiently far apart, say 100 yards, or an intervening pond or increased width of canal must be formed, so that a descending boat does not let off more water than the area below will receive without raising its surface so much as to lose the surplus water over the waste weirs. The mode of overcoming the difference of level between the various level reaches is, with few exceptions, by locks, which generally have a lift of 8 or 10 feet, though in some cases it is somewhat greater. The dimensions of the locks ought to be regulated by the traffic; but they should, in order to save water, be as nearly as possible the size of the craft to be passed through them, allowing from 6 inches to a foot of extra breadth and draught of water. The barge-canals in England have locks about 8 feet in breadth, and from 70 to 80 feet long, and their use in raising or lowering boats from the different reaches is so well known as not to require explanation; and for details as to the construction of the masonry of the chamber and walls, and the timber and iron work of the gates and sluices, reference is made to "Rankine's *Engineering*." The water is generally admitted into and flows from each lock by sluices formed in the gates, and the passage of a boat occupies from three to six minutes, depending on the lift. Sir William Cubitt, on the Severn navigation, introduced the water through a culvert parallel to the side wall of the lock, and opening in the centre by means of a tunnel, which admits of 16,000 cubic feet of water flowing into or out of the lock in $1\frac{1}{2}$ minute; and in little more than that time loaded vessels can be passed through.[1]

Inclined planes.

Inclined planes and perpendicular lifts, which have the advantage of saving water, were adopted so long ago as 1789 on the Ketling Canal in Shropshire, and afterwards on the duke of Bridgewater's canal. Mr Douglas of New York constructed the Morris Canal in the United States with 23 inclined planes, having gradients of about 1 in 10, with an average lift of 58 feet. The boats weighed, when loaded, 50 tons, and after being grounded on a carriage, were raised by water-power up the inclines with great ease and expedition. The length of the Morris Canal, between the rivers Hudson and Delaware, is 101 miles, and the whole rise and fall is 1557 feet, of which 223 were overcome by locks, and the remaining 1334 by inclined planes.[2] When first describing this work the author stated that the principal objection to the inclined planes for moving boats was the injury they were apt to sustain in supporting great weights while resting on the cradle. A slimly-built canal boat, 80 feet long, and loaded with 30 tons, could not be grounded on a smooth surface without straining her timbers, but this objection has to some extent been overcome on an inclined plane constructed by Mr Leslie and Mr Bateman on the Monkland Canal, where the boats are not wholly grounded on the carriage, but are transported in a caisson of boiler-plate containing 2 feet of water, and are thus *water-borne*. This inclined plane is wrought by two high-pressure steam-engines of 25 horse-power each. The height is 96 feet, and the gradient 1 in 10. The maximum weight raised is 80 tons, and the transit takes about ten minutes. The average number of boats passing over the incline is about 7500 per annum. Mr Green introduced on the Great Western Canal a perpendicular lift of 46 feet. Sir W. Cubitt also introduced three inclined planes, having gradients of 1 in 8, on the Chard Canal, Somersetshire.

Perpendicular lifts.

One of these inclines overcomes a rise of 86 feet; and they are said to act very satisfactorily.[3]

An essential adjunct to a canal is a sufficient number of waste-weirs to discharge surplus water accumulating during floods, which, if not provided with an exit, may overflow the tow-path, and cause a breach in the banks, stoppage of the traffic, and damage to adjoining lands. The number and positions of these waste-weirs must depend on the nature of the country through which the canal passes. Wherever the canal crosses a stream a waste-weir should be formed in the aqueduct; but independently of this the engineer must consider at what points large influxes of water may be apprehended, and must at such places not only form waste-weirs of sufficient size to carry off the surplus, but form artificial courses for its discharge into the nearest streams. These waste-weirs are placed at the top water-level of the canal, so that when a flood occurs the water flows over them and thus relieves the banks. The want of these has occasioned overflows of canal banks, attended with very serious injury to the works, and lengthened suspension of the traffic; and attention to this particular part of canal construction is of essential importance.

Stop-gates are necessary at short intervals of a few miles for the purpose of dividing the canal into isolated reaches, so that in the event of a breach the gates may be shut, and the discharge of water confined to the small reach intercepted between two of them, instead of extending throughout the whole line of canal. In broad canals these stop-gates may be formed like the gates of locks, two pairs of gates being made to shut in opposite directions. In small works they may be made of thick planks slipped into grooves formed at the narrow points of the canal under road bridges, or at contractions made at intermediate points to receive them. Self-acting stop-gates have been tried, but their success has not been such as to lead to their general introduction. When repairs have to be made stop-gates allow of the water being run off from a short reach, and afterwards restored with comparatively little interruption to the traffic. Their value in obviating serious accidents has been well exemplified in the author's own experience. The water during a flood flowed over the towing-path of the Union Canal connecting Edinburgh and Glasgow, and the uncontrolled current carried away the embankment and the soil on which it rested to the depth of 60 feet, as measured from the top water-level. The stop-gates were promptly applied, and the discharge confined to a short reach of a few miles, otherwise the injury (which was, even in its modified form, very considerable) would have been enormous, not only to the canal works but to the adjoining lands.

For the purpose of draining off the water to admit of repairs after the stop-gates have been closed, it is proper to introduce, at convenient situations, a series of exits called "offlets," which are pipes placed at the level of the bottom of the canal, and fitted with valves which can be opened when required. These offlets are generally formed at aqueducts or bridges crossing rivers, where the contents of the canal can be run off into the bed of the stream, the stop-gates on both sides being closed so as to isolate the part of the canal from which the water is withdrawn.

In executing the work, provision must be made for the proper drainage of the tow-path, which should be made highest at the side next the canal, and sloped with a gentle inclination towards the outside. The drainage of the tow-path should be carried to a sky drain, and at intervals passed below it into the canal, as shown in fig 3.

ching banks. The preservation of the banks at the water-line is also a matter of importance. "Pitching" with stones and "facing" with brushwood are employed, and in the author's experience the latter, if well executed, forms an economical and effectual protection.

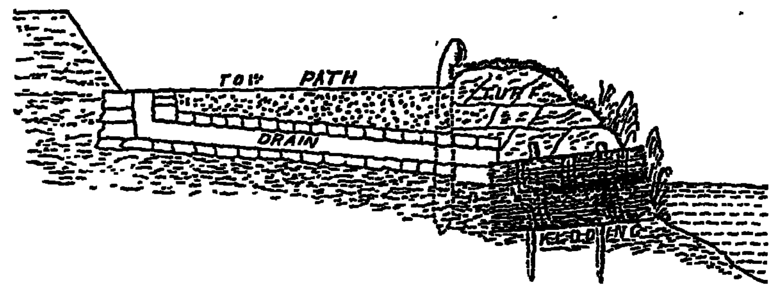

FIG. 3.—Showing Drainage of Tow-path.

ddling. In forming the *alveus* or bed of the canal care must be taken, especially on embankments, and even in cuttings where the soil is porous, to provide against leakage by using puddle, as shown as fig 2. An all-important matter, as affecting the construction of the works, is the possibility of getting clay in the district, or such other soil as may be worked into puddle, on the good quality of which the stability of the reservoir embankments and the imperviousness of the beds and banks of the canal mainly depend.

These are the only points of general application, in the construction of canals, to which reference can here be made; and in applying them to each case the engineer must be guided, *first*, by theoretical knowledge, to be acquired by a careful study of his profession; and, *secondly*, by that knowledge which can be gained only by experience.

le of lucting fic on ls. Not a little has been written on the best mode of conducting traffic on canals, and the reader who wishes to study the subject fully is referred to the observations made by Mr Walker and Mr George Rennie in the *Transactions* of the Royal Society and of the Institution of Civil Engineers, and especially to the valuable researches on hydrodynamics by Mr J. Scott Russell in the *Transactions* of the Royal Society of Edinburgh. Mr Russell while experimenting on propelling boats at high speeds found that the primary wave of displacement produced by the motion of a boat moves with a velocity due to the depth of water in the canal, being the velocity that is due to gravity acting through a height equal to the depth of the centre of gravity of the cross-section of the channel below the surface of the fluid. The velocity is in no degree dependent on the form or velocity of the body which generates it, or on the breadth of the canal. A wave that had a velocity of 8 miles an hour was traced to a point where the channel became deeper, and its velocity was suddenly accelerated; the channel became alternately narrower and wider without producing any sensible effect, but when the wave once more reached that part of the channel which was of the original depth it resumed its original velocity. A fact of great practical value was established, that a boat, if raised by a sudden effort to the top of a primary wave, could be drawn along at 10 miles an hour with less fatigue to the horses than if drawn at the rate of 6 miles, while the waste was less severe on the banks of the canal. These investigations were made before the general establishment of railways, when swift canal travelling seemed a desirable attainment. But though *boats* propelled at high speed on canals have given place to *railway carriages*, yet the canal traffic at slow speeds must be conducted, and the cheapest means of effecting the "haulage" with the least danger to the banks is still an important inquiry, and has within the last few years afforded matter for some highly interesting papers and statements in the *Proceedings* of the Institution of Civil Engineers. These are communications on the employment of steam-power on the Gloucester and Berkeley Canal, by G. W. B. Clegram;[1] on the Grand Canal, Ireland, by Mr Healy;[2] on the Forth and Clyde, by Mr J. Milne;[3] and on the Aire and Calder, by Mr W. H. Bartholomew,[4] to all which reference is made.

One great objection to high speeds on canals is the wasting of the banks by the displacement produced in propelling the vessel through the water. The wasting, indeed, takes place even with very low speeds, and as a matter of canal engineering it is necessary to notice it. To give an instance of the effect on the large scale:—Mr Ure says that the river steamers on the Clyde, going at a speed of 8 to 9 miles per hour, produce a swell which commences to rise when the vessel is "2 or 3 miles off,"—a circumstance which was first noticed by Mr J. Scott Russell in 1837. The swell gradually increases as the steamer approaches, and at last becoming a wave of translation, it breaks on the river walls nearly abreast of the vessel, following her on her course along the river, as a violent breaking wave, measuring 8 or 10 feet from the hollow in the channel to the crest on the wall. A coating of heavy whinstone rock, from 2 to 3 feet thick, extending from low to high watermark is found necessary to enable the banks to withstand it. Mr Ure also found that the action of passing steamers, though very destructive to the banks, was useful in stirring up the mud from the bottom, which was carried off by the currents to an extent which he estimates to be from 20 to 25 per cent. of the whole quantity dredged from one particular part of the river where he carefully measured it. It will at once be apparent, that however inconvenient these wasting waves may be in a river, the waves in a canal, though smaller, are nevertheless a source of greater anxiety, acting as they do in a narrow artificial channel, formed at some places on high embankments, the failure of which would be attended with serious consequences. Was the

The wasting on canals where the traffic is conducted at a moderate speed is found to extend not more than 18 inches to 2 feet, that is 1 foot above and below the water-line, and Mr Clegram states that he has found on the Gloucester Canal that a facing of stone filled into a recess cut in the banks formed a complete protection. Brushwood, as already noticed, is also an effectual remedy.

What has recently led to the consideration of the best means of protecting the banks of canals is the substitution of steam for horse power in working the traffic, which has been entirely successful. The first attempt at using steam-power on canals was made on the Forth and Clyde Canal with Symington's boat, in 1789. Various experiments were made to introduce tugs, but these were ultimately abandoned in favour of steam-lighters, which now in great numbers navigate the canal, and make passages to Leith, Greenock, and other trading ports on the Firths of Forth and Clyde. Steam-towing.

This system, however, would not suit the trade of the Gloucester Canal, which is chiefly frequented by sea-borne vessels, and steam-towing has been introduced on *that* navigation. The following extracts from Mr Clegram's paper[5] seem generally applicable to all navigations where towing is to be adopted. He says the ship canal leads from the Severn at Gloucester to the Severn at Sharpness Point. It is $16\frac{1}{2}$ miles in length, and has a depth varying from 18 to 18 feet 6 inches, navigable by vessels of 700 tons register. Prior to the year 1860 all sea-going vessels passing through were towed by horses, the number of horses being regulated by a scale varying from 1 horse for a vessel of 40 tons to 9 horses for a vessel of 420 tons. The cost of this amounted generally to about one farthing per ton per mile on the Steam-towing on Gloucester Canal.

[1] *Minutes of Proceedings of Institution of Civil Engineers*, vol. xxvi. p. 1. [2] *Ibid.*, p. 6. [3] *Ibid.*, p. 10.
[4] *Ibid.*, p. 25. [5] *Ibid.*, p. 1.

register tonnage of the vessel. The speed varied from one mile to three miles per hour, according to the size of the vessel and the state of the weather.

In 1860 steam-tugs were placed upon the canal to do this work. They are iron boats, 65 feet long, 12 feet beam, and draw 6 feet 3 inches of water, fitted with high-pressure engines; the diameters of the cylinders are 20 inches, stroke of 18 inches, pressure of the steam 32 ℔ on the inch, and the cost of each £3000. Nearly the whole of the sea-going craft are now towed by these tugs. The vessels range from 30 tons up to 700 tons register, with a draught of water from 6 to 16 feet. They are towed either singly or in a team, according to circumstances. Sometimes as many as thirteen loaded vessels of from 50 to 100 tons register have been towed by one tug at the rate of 3 to $3\frac{1}{2}$ miles an hour. The heaviest load drawn by any one tug has been 1690 tons of goods in three vessels. Their draught of water varied from 14 feet 6 inches to 15 feet 6 inches, and they were taken the whole length of the canal at the speed of 2 miles an hour. The smaller vessels are towed at a speed of 4 miles an hour, to which as a rule they are restricted.

The employment of steam for towing has been found very advantageous. The vessels rub less against the banks, the power being right ahead, and not on one side as with horses. The wear on the ropes used in tracking is reduced, the speed is increased, and vessels can be moved along the canal in weather which would have prevented horses doing the work. With a strong wind athwart the canal vessels cannot be tracked *in train;* they must then be taken singly, or at most two at a time. When vessels are towed in train, as a rule the largest and heaviest draughted are placed first, and the hawser leading from the first vessel to the tug is taken from each side of the bow. With this arrangement, and a skilful management of the tug, the vessels can be kept *fairly* in the line of the canal.

The only disadvantage of this system, on a canal the sides of which are unprotected, is the additional wear caused by the run of water between the sides of the large vessels and the banks. Such vessels occupy a large part of the sectional area of the canal, and being taken along at a much greater speed than they were by horses the wash of water is more prejudicial. When the vessels or trains of vessels are heavy, and the tugs are working up to their full power and speed, the water thrown back by the action of the screw against the bow of the first vessel is thrown off by it to the banks on either side, and is the cause of considerable wash. This has been attempted to be remedied by placing the first vessel farther back from the tug; but in practice it is found that a distance of 40 to 50 feet is the farthest separation that can be allowed without sacrificing that *hold* between the two which prevents the vessel sheering from side to side. The first vessel being kept steadily in her course, the others follow without much difficulty.

The employment of tugs has afforded an unexpected facility for cleansing the canal from deposit of mud. Formerly it was difficult to remove this deposit from the slopes of the banks on which it collected, sometimes inconveniently contracting the capacity of the canal. Since the vessels have been moved at greater speed and *in trains* this deposit has been entirely removed from the slopes to the bottom of the canal, whence it can readily be taken out by the dredger.

But though all efforts to improve barge-canals can never bring them to compete with railways in the quick conveyance of passengers, it is surprising to find in how many places they still command an enormous traffic in goods and minerals, and thus act as a valuable relief to overburdened railways. This is specially the case in the manufacturing districts of England, where the Birmingham Grand Junction and other canals seem to carry on as brisk a trade as they did in days gone by when they had no competitors but the stage coach and the carrier's van.

Ship canals

These remarks, however, as to railway competition do not apply to Ship-canals, which, undisturbed by competing schemes, retain all the monopoly they ever possessed; and indeed, in the recent construction of the Suez and New Amsterdam canals, they have acquired an importance before unclaimed for works of that class—an importance which entitles them to the highest consideration in any engineering treatise; for, apart from their structural interest to the engineer, their usefulness in affording a short and sheltered passage for sea-borne vessels has long been acknowledged and can hardly be over-estimated.

The Languedoc Canal already mentioned, by a short passage of 148 miles, saves a sea voyage of upwards of 2000 miles through the Straits of Gibraltar. By the Forth and Clyde Canal sea-borne vessels, not exceeding $8\frac{1}{2}$ feet draught of water, can pass from opposite coasts of Scotland, through the heart of the country, by 35 miles of inland navigation and avoid the dangers of the Pentland Firth; the Crinan Canal substitutes a short inland route of 9 miles for a sea voyage round the Mull of Kintyre of about 70 miles; and the last great canal between Suez and the Mediterranean effects a saving of 3750 miles on the route to India.

To most of the early ship canals that have been executed, the principles of construction already stated are generally applicable—the depth of water and dimensions of the locks and all other works being increased to suit the larger size of craft which use them, and therefore further notice of such details is not required. But having still to illustrate the larger class of works, we proceed to describe some of the largest of the ship-canals already constructed and projected, and in doing so, we shall consider ship-canals under the following three classes :—

Th... clas... ship

First, Canals which on their route from sea to sea traverse high districts, surmounting the elevation by locks supplied by natural lakes or artificial reservoirs, such as the Languedoc in France, or the Caledonian Canal in Scotland;

Second, Canals in low-lying districts, which are carried on a uniform water-level from end to end, and are defended against the inroad of the sea at high water by double acting locks, which also retain the canal water at low tide, such as the canals of Holland and other low countries;

Third, Canals, of which the Suez is the only example yet made, without locks at either end, and communicating freely with the sea, from which it derives its water supply.

Ca... C...

The Caledonian Canal in Scotland is as good a specimen of works of the *first* class as can be selected.

In 1773 James Watt was employed to survey the country between the Beauly at Inverness and Loch Eil at the mouth of the river Lochy, a distance of about 60 miles, with the view of forming a ship canal between the two seas, to save about 400 miles of coasting voyage by the North of Scotland through the stormy Pentland Firth. The district referred to, called the "Great Caledonian Glen," as will be seen from Plate XXXVI., embraces a chain of fresh-water lakes, which, in connection with the surrounding glens, have afforded an interesting field for the speculations of the geologist; and no doubt the first conception of a canal through the district owed its origin to the apparent facilities for inland navigation which the lakes afforded.[1] In 1801 Telford was employed by Government to report, and the ultimate result of that report was the construction of the canal.

The district which discharges into the eastern outlet comprehends an area of about 700 square miles, chiefly of high mountainous country, intersected by streams and lakes, which discharge themselves into Loch Oich, Loch Ness, and Loch Doughfour, and thence are conveyed into the Moray Firth by the River Ness. Loch Oich, the summit-level of the canal, has an area of about 2 square miles, and the present standard level of its surface is understood to be 102 feet above the level of mean high water of neap tides in Beauly Firth. It receives the drainage of Loch Quoich and Loch Garry. The waters of Loch Oich are discharged through the River Oich into Loch Ness, which is about 24 miles in length, and has an area of about 30 square miles. Loch Ness receives the waters of the Tarff, the Foyers, and Glenmoriston, and the drainage of numerous other streams and lakes of less note. It discharges its waters through a comparatively narrow neck, called Bona Passage, into the small loch of Doughfour, whence they find an exit to the Beauly and Moray Firths by the River Ness, on which the town and harbour of Inverness are situated.

The drainage of the western district of the country, including Loch Arkegg, finds its way into Loch Lochy, which is about 10 miles long, and thence by the River Lochy to the Western Sea at Loch Eil.

The two locks in Loch Beauly at the northern entrance to the canal are each 170 feet long, 40 feet wide, and have a *lift* of about 8 feet. At Muirtown, a little further on, are four locks of 170 feet in length and 40 feet in width, having a rise of 32 feet, raising the canal to the level of Loch Ness, which it enters at Bona. The works westward of Loch Ness are an artificial canal with seven locks communicating with Loch Oich. Between Lochs Oich and Lochy are two locks; at the south end of Loch Lochy is a regulating lock, and the canal is carried from this point on the level of Loch Lochy to Banavie, where it descends 64 feet by eight connected locks, forming what is called in the country "Neptune's Staircase;" finally at Corpach the canal descends by two locks to the level of Loch Eil.

Of the whole distance, about $37\frac{1}{2}$ miles are natural lake navigation, and the remaining 23 are artificial or canal navigation. The canals were made 120 feet in width at top-water level, 50 feet at bottom, and 20 feet in depth. In the course of inquiries as to the state of the canal, under a remit from the Admiralty, the author found that the shallows at Loch Oich and the cutting at the summit level originally contemplated had not been carried to the full depth, and an additional depth had been gained at that place by raising the level of Loch Oich; but still he was led to the conclusion that the standard depth of the canal cannot be regarded as more than 18 feet, giving access to vessels of 160 feet in length, 38 feet beam, and 17 feet draught of water.[1]

In carrying out this remarkable work Telford had to deal with difficulties of no ordinary kind, in rendering available rugged Highland lakes, and surmounting the summit-level of the glen. The work, which cost about one million sterling, is a noble monument of his engineering skill.

s of
ud.

The canals of Holland are specimens of the *second* class of works to which reference has been made, and of these a very remarkable one is the North Holland Canal, completed in 1825. It was designed by M. Blanken, who, instead of the high rugged Highland glens of Scotland, had to deal with the proverbial lowness of the country, and to protect his works not from the assaults of mountain torrents but from encroachments of the waves, for there vessels are locked *down* from the sea into the canal. It extends from Amsterdam to the Helder, is 50 miles in length, and is formed of the cross-section shown in fig. 4. It enables vessels trading from Amsterdam to avoid the islands and sand-banks of the dangerous Zuider-Zee, the passage through which in former times often occupied as many weeks as the transit through the canal now occupies hours.

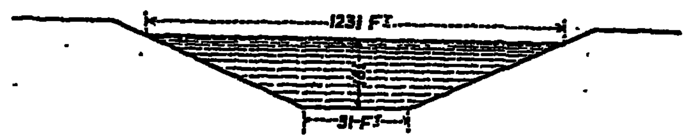

FIG. 4.—Cross-section of North Holland Canal.

But the North Holland Canal, which has long proved so useful to the commerce of the district, is destined soon to be superseded by the new Amsterdam Canal, a work of great magnitude, which it is proposed to describe as an illustration of ship-canals of the *second* class from details furnished by Mr J. C. Hawkshaw, C.E. Amsterdam Canal

The rapid increase in the trade of the ports to the southward and eastward of the Helder, effected by the construction of railways throughout Europe, rendered it imperative for the merchants of Amsterdam to provide better communication with the North Sea than that afforded by the North Holland ship canal already noticed, or suffer its trade to pass to other ports more favourably situated for over-sea traffic.

In 1865 a company was formed for the purpose of constructing a canal from Amsterdam, in nearly a direct line, to the North Sea, through Lake Y and Wyker Meer, a distance of $16\frac{1}{2}$ miles. Sir John Hawkshaw and Mr Dirks were appointed the engineers to carry out the work, a plan and section of which are given in Plate XXXVI.

The harbour in which the canal terminates in the North Sea is formed by two piers built of concrete blocks founded on a deposit of rough basalt. The piers are each 5069 feet in length, and enclose an area of about 260 acres. About 140 acres of this area are to be dredged to a depth of $26\frac{1}{4}$ feet, the remainder is to be left at the present depth for the accommodation of small craft and fishing-boats.

From its commencement at the harbour the canal passes by a deep cutting through a broad belt of sand-hills which protect the whole of this part of the coast of Holland from the inroads of the sea. The cross-section of the canal at this place is shown in fig. 5. This cutting is about 3 miles

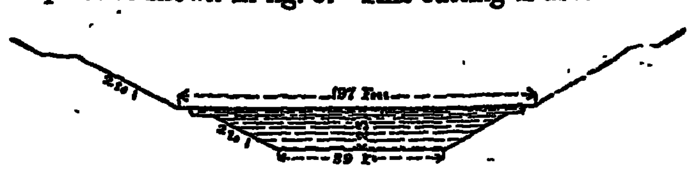

FIG. 5.—Cross-section of Amsterdam Canal.

in length; the greatest depth of cutting from the surface to the bottom of the canal is 78 feet, and the amount of earthwork excavated is 6,213,000 cubic yards. On emerging from the sand-hills the canal passes by the village of Velsen, in the neighbourhood of which it is crossed by the railway from Haarlem to the Helder, and there enters the Wyker Meer, a large tract of tide-covered land. After traversing the Wyker Meer it passes by a cutting of 327,000 cubic yards through the promontory called Buitenhuizen, which separates that Meer from Lake Y, another large tide-covered area. The rest of its course lies through Lake Y as far as Amsterdam.

There are two sets of locks, one set at each end. The North Sea locks are at a distance of about three-quarters of a mile from the North Sea harbour. These locks, as shown in fig. 6, have three passages. The central or main one is 60 feet wide and 390 feet long, and will be furnished with two pairs of gates at each end, pointing in opposite direc-

[1] *Report on the Caledonian Canal to the Admiralty*, 1849, by James Veitch, R.E., and David Stevenson, C.E.

tions, and one pair in the centre. The northernmost side passage for barges is 30 feet long and 34 feet wide, with three pairs of gates; that to the south is 227 feet in length and 40 feet wide, with five pairs of gates.

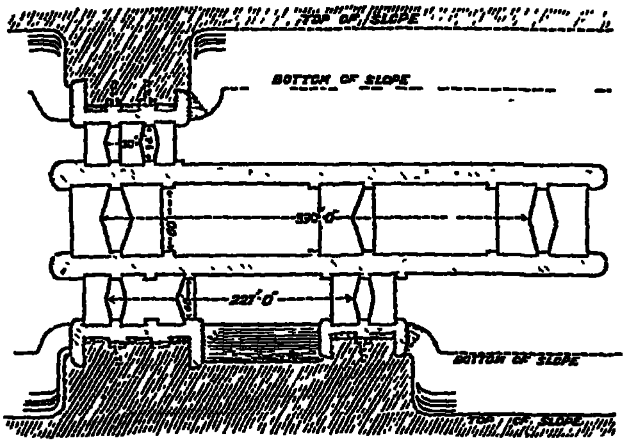

FIG. 6.—Plan of Locks on Amsterdam Canal.

In constructing the canal, which is (1876) now far advanced towards completion, the cuttings were first begun. The material proceeding from these cuttings was deposited so as to form two banks 443 feet apart, through the lakes on each side of the main canal, as shown by the hard lines on the plan, and also to form the banks of the branch canals on either side. The total length of these banks is 38½ miles. The nucleus of the bank is formed of sand with a coating of clay, and protected during its progress with fascines; and when the banks are far enough advanced, the deep channel for the canal is excavated by dredging. The cross-section of the canal and banks through these meers or lakes is shown in fig. 7.

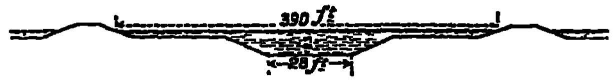

Fig. 7.

The formation of the banks through the Wyker Meer and Lake Y will enable about 12,000 acres of the area, as shown on the plan, which is now occupied by these lakes, to be reclaimed. For the purpose of this reclamation, and also to provide for the drainage of the land on the margin of the lakes, including a large portion of what was formerly Haarlem Meer, pumps are provided by the company at various points on the main and branch canals. The Canal Company are bound to keep the surface-water of the canal about 1 foot 7 inches *below* average high-water level. In order to insure this level being maintained, three large pumps have been erected in connection with the locks hereafter to be described, on the dam between Amsterdam and the Zuider Zee. They consist of three Appold pumps, the largest of the kind yet made, the fans being 8 feet in diameter. Each pump is worked by a separate engine of 90 nominal horse-power. The maximum lift is 9 feet 9 inches, at which the three pumps are capable of discharging 1950 tons a minute; with the ordinary working lift of 3½ feet they will discharge 2700 tons a minute.

Lake Y extends about 4½ miles to the eastward of Amsterdam; and here it was necessary to form a dam with locks for the passage of vessels. The dam crosses Lake Y at a point about 2 miles to the eastward of Amsterdam, where it is contracted to 4265 feet in width. As it was necessary to construct these locks before completing the dam across Lake Y, a circular cofferdam 590 feet in diameter, consisting of two rows of piles 49 feet long, was constructed in the tideway, and within this dam the locks were built. These locks have three main passages, each with five pairs of gates, and one smaller passage with three pairs of gates, arranged much in the same manner as the North Sea locks in fig. 6. The whole of the masonry and brickwork for these locks and sluiceways was founded on bearing-piles, upwards of 10,000 in number. The bottom where the cofferdam was placed consisted of mud, and some difficulty was experienced in maintaining it till the work was completed. The dam across Lake Y, as shown in section, fig. 8, consists of clay and sand, placed on and

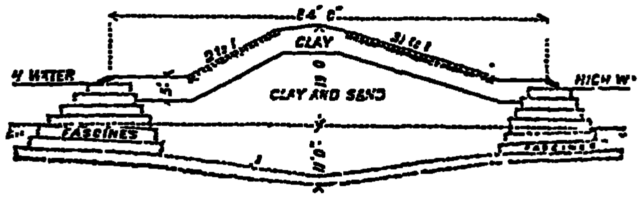

FIG. 8.—Section of Dam across Lake Y.

protected at the sides by large masses of wicker-work, which is afterwards covered with basalt in the manner usually adopted in Holland.

All the lock gates at both ends of the canal pointing seawards are of malleable iron; the gates pointing inwards towards the canal are of wood. The necessity, for drainage purposes, of maintaining the surface water of the canal at the prescribed low level calls for a sufficient barrier being provided against the sea at both ends, as the sea-level will not unfrequently, at high water, be several feet above the level of the canal. This necessity, as well as the difference of level and periods of high water in the Zuider Zee and the North Sea, required a totally different design from the Suez Canal, to be afterwards described. The contract sum for the execution of the Amsterdam Canal is £2,250,000, and it is expected that it will be ready for traffic in 1877.

Of the *third* class of works there is, as yet, only a single example in the Suez Canal, one of the most remarkable engineering works of modern times; but though it is called a canal, it bears little resemblance to the works we have described under that name, for it has neither locks, gates, reservoirs, or pumping engines, nor has it, indeed, anything in common with canals, except that it affords a short route for sea-borne ships. It is in fact, correctly speaking, an artificial strait or arm of the sea, connecting the Mediterranean and the Red Sea, from both of which it derives its water-supply; and the fact that the two seas are nearly on the same level, and the rise of tide very small, allowed this construction to be adopted.

The idea of forming this connecting link between sea and sea is of very ancient origin, and its author is unknown. It is understood, however, that a water communication for small vessels between the two seas was formed as early as 600 years before the Christian era, and existed for a period of about 1400 years, after which it was allowed to fall into disuse. Baron De Tott in his *Memoirs of the Turks and Tartars*,[1] written in 1785, after giving quotations from the historian Diodorus as to the existence of certain portions of the early work, and its having been abandoned in consequence of the supposed difference of level between the two seas, and threatened inundation of Egypt, says there still exist those early traces of work "qu'un léger travail rendrait navigable sans y employer d'écluses et sans menacer l'Égypte d'inondations." De Tott's opinion expressed in 1785 has certainly been carried out, but on a scale and at an expenditure of labour and money far beyond the conception of the French diplomatist.

The idea of restoring this ancient communication on a

[1] *Mémoires du Baron de Tott, sur les Turcs et les Tartares*, Amsterdam, 1785, vol. ii. p. 271.

scale suited to modern times is understood to be due to Napoleon I. who, about the close of the last century, obtained a report from M. Lepère, a French engineer, which however was followed by no result, and it remained for M. de Lesseps, in the present day, to realize what were thought the dreams of commercial speculators, by carrying out the long-desired passage between the two seas. But the postponement of the scheme unquestionably favoured the chances of its commercial success, for had the canal been completed even a few years earlier, comparatively few vessels would have been found to take advantage of it. Masters of sailing-vessels would not from choice have navigated the Mediterranean and encountered the passage through the canal and the tedious and difficult voyage of the Red Sea. They would undoubtedly have preferred to round the free seaway of the Cape of Good Hope, with all its ocean dangers and excitements, to threading their way through such an inland passage, involving risks of rocks and shoals, protracted calms and contrary winds. But the introduction of ocean-going screw-steamers was an entirely new feature in navigation. Being independent of wind for their propulsion, and being admirably fitted for navigating narrow straits and passages, their rapid and general adoption by all the leading shipping firms in the world afforded not only a plea, but a necessity for the short communication by the Mediterranean and Red Sea. It was indeed a great achievement to reduce the distance between Western Europe and India from 11,379 to 7628 miles, equal, according to Admiral Richards and Colonel Clarke, R.E., to a saving of thirty-six days on the voyage; and this is the great result effected by cutting the Suez Canal between the Mediterranean and the Red Sea.

Mr Bateman, C.E., who visited the canal as the representative of the Royal Society, communicated to that body a description of the works, in which he gives the following account of the early negotiations of M. Ferdinand Lesseps, who has the credit of having brought the work to a successful issue:[1]—

"The project" of M. Ferdinand Lesseps "was to cut a great canal on the level of the two seas, by the nearest and most practicable route, which lay along the valley or depression containing Lake Menzaleh, Lake Ballah, Lake Timsah, and the Bitter Lakes. The character of this route was described in 1830 by General Chesney, R.A., who examined and drew up a report on the country between the Mediterranean and the Red Sea. At that time a difference of 30 feet between the two seas was still assumed, and all proposals for canals were laid out on that assumption. General Chesney summed up his report by stating, —'As to the executive part there is but one opinion; there are no serious difficulties; not a single mountain intervenes, scarcely what deserves to be called a hillock; and in a country where labour can be had without limit, and at a rate infinitely below that of any other part of the world, the expense would be a moderate one for a single nation, and scarcely worth dividing among the great kingdoms of Europe, who would all be benefited by the measure.'

"M. Lesseps was well advised therefore in the route he selected, and (assuming the possibility of keeping open the canal) in the character of the project he proposed.

"From 1849 to 1854 he was occupied in maturing his project. In the latter year Mahomet Saïd Pasha became Viceroy of Egypt, and sent at once for M. Lesseps to consider with him the propriety of carrying out the work. The result of this interview was, that on the 30th of November a commission was signed at Cairo, charging M. Lesseps to constitute a company named 'The Universal Suez Canal Company.' In the following year, 1855, M. Lesseps, acting for the Viceroy, invited a number of gentlemen, eminent as directors of public works, as engineers, and distinguished in other ways, to form an International Commission for the purpose of considering and reporting on the practicability of the scheme.

"The Commission met in Egypt in December 1855 and January 1856, and made a careful examination of the harbours in the two seas, and of the intervening desert, and arrived at the conclusion that a ship canal was practicable between the Gulf of Pelusium in the Mediterranean and the Red Sea near Suez. They differed, however, as to the mode in which such a canal should be constructed. The three English engineering members of the Commission were of opinion that a ship canal, having its surface raised 25 feet *above* the sea-level, and communicating with the Bay of Pelusium at one end and the Red Sea at the other, by means of locks, and supplied with water from the Nile, was the best mode of construction. The foreign members, on the contrary, held that a canal having its bottom 27 feet *below* sea-level, from sea to sea, without any lock, and with harbours at each end, was the best system,—the harbours to be formed by piers and dredging out to deep water.

"The Commission met at Paris in June 1856, when the views of the English engineers were rejected, and the report to the Viceroy recommended the system which has since been carried out....

"Two years from the date of this report were spent in conferences and preliminary steps before M. Lesseps obtained the necessary funds for carrying out the works. About half the capital was subscribed on the Continent by far the larger portion being taken in France, and the other half was found by the Viceroy. Further time was necessarily lost in preparation, and it was not till near the close of 1860 that the work was actually commenced.

"The original concession granted extraordinary privileges to the Company. It included or contemplated the formation of a 'sweet water' canal for the use of the workmen engaged, and the Company were to become proprietors of all the land which could be irrigated by means of this canal. One of the conditions of the concession also was that the Viceroy should procure forced labour for the execution of the work, and soon after the commencement of operations, and for some time, the number of workmen so engaged amounted to from 25,000 to 30,000. The work thus commenced steadily proceeded until 1862, when the late Viceroy, during his visit to this country at the time of the International Exhibition, requested Sir John Hawkshaw to visit the canal and report on the condition of the works and the practicability of its being successfully completed and maintained. His Highness's instructions were that Sir John Hawkshaw should make an examination of the works quite independently of the French company and their engineers, and report the results at which he arrived."

We quote these results as given in Sir John Hawkshaw's report, because they show the nature of the difficulties that had been raised and the soundness of the advice which Sir John gave—advice which undoubtedly greatly contributed to the successful completion of the work.

The following are given by Sir John as the *objections to* the work:—

"1. That the canal will become a stagnant ditch.

"2. That the canal will silt up, or that the moving sands of the Desert will fill it up.

"3. That the Bitter Lakes through which the canal is to pass will be filled up with salt.

"4. That the navigation of the Red Sea is dangerous and difficult.

"5. That shipping will not approach Port Saïd, because of the difficulties that will be met with, and the danger of that port on a lee shore.

"6. That it will be difficult, if not impracticable, to keep open the Mediterranean entrance to the canal."

Having analysed each of these objections, and fully weighed the arguments on which they were based, he came to the following conclusions as to the practicability of construction and maintenance:—

"*1st*, As regards the engineering construction, there are no works on the canal presenting on their face any unusual difficulty of execution, and there are no contingencies that I can conceive likely to arise that would introduce difficulties insurmountable by engineering skill.

"*2dly*, As regards the maintenance of the canal, I am of opinion that no obstacles would be met with that would prevent the work, when completed, being maintained with ease and efficiency, and without the necessity of incurring any extraordinary or unusual yearly expenditure."

"Saïd Pasha died between the period of Sir John Hawkshaw's examination of the country and the date of his report. He was succeeded by his brother, Ismail, the present Viceroy or Khedive, who, alarmed at the largeness and uncertainty of the grants to the Canal Company, of the proprietorship of land which could be irrigated by the sweet water canal, and anxious to retire from the obligation of finding forced labour for the construction of the works, refused to ratify or agree to the concessions granted by his brother. The whole question was then referred to the arbitration of the late Emperor of the French, who kindly undertook the task, and awarded the sum of £3,800,000 to be paid by the Viceroy to the Canal Company as indemnification for the loss they would sustain by the withdrawal of forced or native labour, for the retrocession of large grants of land, and for the abandonment of other privileges attached to the original act of concession. This money was applied to the prosecution of the works.

"The withdrawal of native labour involved very important changes in the mode of conducting the works, and occasioned at the time considerable delay. Mechanical appliances for the removal of the material, and European skilled labour, had to be substituted; these had to be recruited from different parts of Europe, and great difficulty was experienced in procuring them. The accessory canals had to be widened for the conveyance of larger dredging-machines, and additional dwellings had to be provided for the accommodation of European labourers. Ultimately all difficulties were overcome, and the work proceeded."

After the works had been nearly completed, the Lords of the Admiralty instructed Admiral Richards, the hydrographer, and Lieutenant-Colonel Clarke, R.E., to visit Egypt, and report as to the condition of the canal. These officers accordingly made a most minute survey of the canal and its terminal harbours, and issued a most interesting report,[1] from the information contained in which the plan of the canal, Plate XXXVI., has been mainly constructed. From this plan it will be seen that the canal extends from Port Saïd on the Mediterranean to Suez on the Red Sea, and that, as shown by the section, it traverses a comparatively flat country. This route has been selected so as to take advantage of certain valleys or depressions which are called lakes, but were in fact, previous to the construction of the canal, low-lying tracts of country, at some places below the level of the Mediterranean and Red Seas. These valleys were found to be coated with a deep deposit of salt, and are described as having had all the appearance of being covered with snow, bearing evidence of their having been at one period overflowed by the sea. As will be seen from the plan, Lake Menzaleh is next to the Mediterranean, Lake Timsah about half-way across the isthmus, and the Bitter Lakes next to the Red Sea. Lake Timsah, which is about 5 miles long, and the Bitter Lakes, about 23, were quite dry before the cutting of the canal, and the water which has converted them into large inland lakes was supplied from the Red Sea and Mediterranean. The water began to flow from the Mediterranean in February 1869, and from the Red Sea in July, and by the beginning of October of the same year these vast tracts of country, which had formerly been parched and arid valleys, were converted into great lakes navigated by vessels of the largest class. It will be seen from the section that the surface of the ground is generally very low, the chief cuttings being at Serapeum and El Guisr, where the sandy dunes attain an elevation of about 50 to 60 feet. The channel through the lakes was excavated partly by hand labour and partly by dredging, and for a considerable portion the level of the valleys was so low as to afford sufficient depth without excavation. The material excavated appears to have been almost entirely alluvial, and easily removed; the only rock was met with at El Guisr, where soft gypsum occurred, removable to a considerable extent by dredging, so that the canal works presented no physical difficulty.

The whole length of the navigation is 88 geographical miles. Of this distance 66 miles are actual canal, formed by cuttings, 14 miles are made by dredging through the lakes, and 8 miles required no works, the natural depth being equal to that of the canal. Throughout its whole length the canal was intended to have a navigable depth of 26 feet for a width of 72 feet at the bottom, and to have a width at the top varying according to the character of the cuttings. At those places where the cuttings are deep, the slopes were designed to be 2 to 1, with a surface width at the water-line of about 197 feet, as shown in fig. 9, which

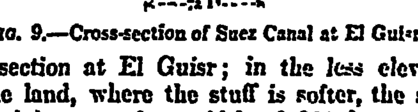

Fig. 9.—Cross-section of Suez Canal at El Guisr.

is a cross-section at El Guisr; in the less elevated portions of the land, where the stuff is softer, the slopes are increased, giving a surface width of 325 feet. It will be understood that in the lakes the canal consists of a navigable channel of sufficient depth and breadth to admit the traffic, the surface of the water extending on either side to the edge of the lake. Fig. 10 shows a cross-section at Lake

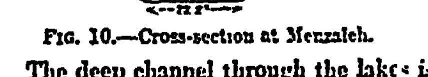

Fig. 10.—Cross-section at Menzaleh.

Menzaleh. The deep channel through the lakes is marked by iron beacons on either side, 250 feet apart, and the Admiralty reporters state that "in practice it is found more difficult to keep in the centre while passing through these beacons, than it is when between the embankments." At every 5 or 6 miles there is a passing-place, to enable large vessels to moor for the night, or to bring-up in order to allow others to pass, all these movements being regulated by telegraph from Port Saïd, Ismailia, or Suez. Perhaps the most interesting question to the engineer is the action of the tide in the narrow channel between the two seas, and the observations made on this subject are given in the following quotation from the Admiralty report:—

[1] *Report on the Maritime Canal connecting the Mediterranean at Port Saïd with the Red Sea at Suez*, February 1870.

filled from the Mediterranean in April 1867, has risen 12 centimetres, or about 4 inches, and that its waters are continually running at a slow rate into the Mediterranean; certainly this statement agreed with what we ourselves remarked, for we always found a current running northward from Lake Timsah at the rate of from half a mile to a mile an hour. Limited, however, as these tidal observations were, they were taken with great care, and appear sufficient to show that, except at the Suez end, the tides will not materially affect the passage of vessels; at that end, therefore, large vessels must regulate their time of passing; indeed, the greatest difficulty which will be experienced will be not from the tides, but from the prevailing north-east wind in the canal, which will make close steerage difficult in going from north to south."

It thus appears that the tidal column of 5 feet range in the Red Sea is reduced to 2 feet at the distance of 6 miles, and is practically annihilated by the wide expanse of the Bitter Lakes. But it would be highly interesting to have this conclusion confirmed by further systematic tidal observations.

In executing this strange work of the desert, and converting dry sands into navigable lakes, it is stated that there have been about *eighty millions* of cubic yards of material excavated, and at one time sixty dredging-machines and nearly 30,000 labourers were employed. For their use a supply of fresh water was conveyed from the Nile at Cairo, and distributed along the whole length of the canal, a work which of itself was one of no small magnitude.

The cost of the whole undertaking, including the harbours, is stated to have been about £20,000,000. The terminal harbours are important adjuncts of this great work. That on the Mediterranean is Port Saïd, which is formed by two breakwaters constructed of concrete blocks, the western one 6940 feet in length and the eastern 6020 feet, enclosing an area of about 450 acres, with an average depth of only 13 or 14 feet, excepting in the channel leading to the canal, where the depth is 25 to 28 feet. The entrance to the canal at Suez is also protected by a breakwater, and in connection with the harbour at this place there are two large basins and a dry dock.

The canal may be regarded as a highway for steamers of 400 feet in length and 50 feet beam. A delay of three days is calculated on for the passage across from Port Saïd to Suez.

It is satisfactory to learn from the report of Commander Wharton, of H.M.S. "Shearwater," "that the canal retains its depth of water. That report states that "comparing generally the depth of the canal in 1873 and 1875 it seems that it is in about the same condition, with perhaps a slight balance in favour of increased depth now; while its average minimum may be stated at 26 feet, there are yet considerable tracts where 25 feet and even as little as 24 feet will be passed over." The survey of Lieutenant Millard, also reported to the Admiralty in 1875, shows that at the entrance to Port Saïd harbour the 27, 30, and 33 feet contour lines were seaward of those obtained before, proving that some shallowing of the water at the entrance has taken place.

The use made of the canal may be judged of from the following table of the traffic passing through since its commencement[1]:—

Year.	Number of Vessels.	Gross Tonnage.	Receipts.
1870	486	654,915	£206,373
1871	765	1,142,200	359,748
1872	1082	1,744,481	656,303
1873	1173	2,085,072	915,892
1874	1264	2,423,672	994,375

The tonnage has thus been quadrupled in five years; and the best means of enlarging the canal to accommodate increasing trade must soon become an important question for its owners.

Such works as the ship canals we have been describing entirely revolutionize ocean navigation, and consequently demand the zealous attention of all nations whose interests they seem to affect. Of this zealous watchfulness the interest taken by the Powers of Europe in the distribution of the property in the Suez Canal may be cited as an example. But notwithstanding the difficulties, legal and political, which the execution of such works are almost sure to create by severing continents before united, and connecting seas before separated by thousands of miles of exposed navigation, we may safely conclude that wherever the perils and delays of ocean sailing can be lessened by forming canals these valuable helps to navigation will at all hazards be carried out. Viewing then the subject *prospectively*, we offer no apology for noticing two important short sea passages which, though still unexecuted, will doubtless in some form be eventually carried out.

Proposed Paumben canal.

One of these canals is designed to obviate the navigation of the dangerous strait between Ceylon and the mainland of India, which is shallow and narrow, and in some states of the wind has a violent current, so that it can only be navigated by vessels of small draught. Ships of the larger class have to circumnavigate Ceylon in making their passages to the eastern section of Hindustan. The importance of avoiding this detour round Ceylon of 350 miles of exposed navigation in the direct Suez route to Calcutta and Madras will be readily acknowledged, and the execution of the work cannot long be delayed.

The strait to which we allude is the Paumben passage leading from the Gulf of Manaar on the west to Palk Bay on the east, as shown in fig. 11, and many attempts have been made by blasting to clear away the rocky obstructions that at present render its navigation dangerous. But in order to provide a safe passage of the strait between Ceylon and India for the ships which now navigate the Suez Canal, nothing will suffice but a canal affording the same depth and width, though very much shorter in length than its great pioneer in shortening ocean sailing; and accordingly surveys have been made and schemes have been proposed to effect this important improvement. Mr George Robertson, Civil Engineer, when inspecting the harbours of India, was asked by the British Government to visit the locality and report on these schemes; and from his Report on Indian Harbours we find that the site he selected as most suitable is through the island of Ramaseram, about a mile east from Paumben lighthouse. The distance across from sea to sea is about 2 miles, the ground being a flat sandy plain, raised on an average about 7 feet above high water, and from the borings that have been made it is not expected that much rock will be found in the course of the canal. In order to assimilate it to the Suez Canal the navigable depth should if possible be about 26 feet. On the north side the distance from high water mark to 30 feet at low water is, according to a chart by the Surveyor-General at Colombo, upwards of a mile; on the south side the distance to the same depth is still greater, so that very considerable works of dredging will be necessary in forming and afterwards maintaining the entrances to the canal. The south end of the canal is under shelter of a coral reef, but the north end may perhaps require to be protected by breakwaters. The cost of cutting the canal has been named at £440,000.

Isthmian canal.

The other scheme to which we referred has a far higher stage of importance, its object being to separate the continents of North and South America, and to give a free navigation between the Atlantic and the Pacific Oceans, by overcoming the physical difficulties presented by the climate and the geological formation of the Isthmus that separates the two

[1] *The History of the Suez Canal*, by F. de Lesseps, translated by Sir H. D. Wolff, 1876.

seas, to which has to be added the problem of making and maintaining a deep-water channel from the ocean to the entrances to the canal

This bold scheme, first proposed in the 16th century, has at various intervals been the subject of many deputations and much correspondence between the American and European powers; and more recently, in 1845, when Louis Napoleon was confined as a state prisoner at Ham, he spent much of his exile in investigating its practicability, and in making arrangements for carrying out, under the name of the "Napoleon Interoceanic Canal," a passage between the two seas from Port San Juan to Port Realejo. But we have not space to record the various early attempts to realize this project, and must therefore confine our remarks to giving an idea of the present state of negotiations regarding it.

The recent enormous growth of Californian trade has led to the revived consideration of the scheme by the United States of America, who would be the greatest gainers by the work, and therefore are its most natural promoters; and what we propose is to give a sketch of the present state of the question, as afforded by reports and documents recently issued by the Government of the United States, from which alone authentic information can be derived.

It appears from these documents that two routes have recently been investigated:—*First*, that of the Isthmus of

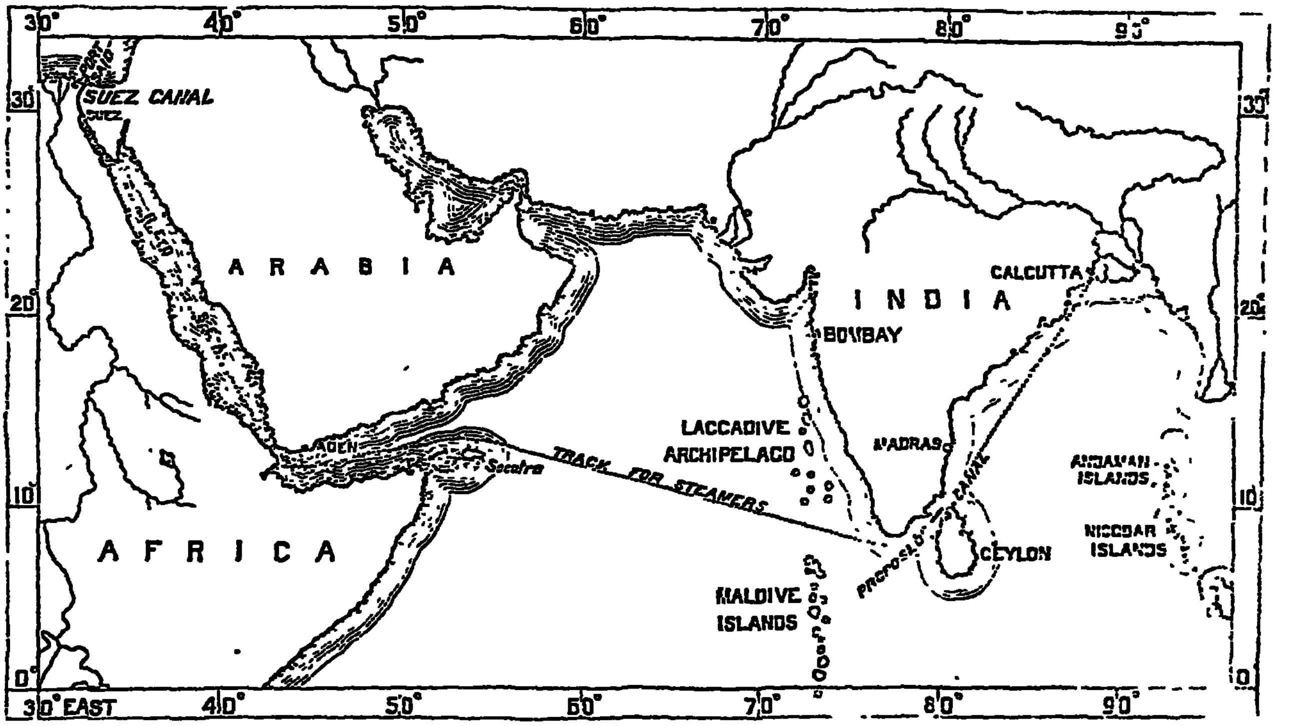

Fig. 11.—Showing Suez Canal and Proposed Canal at Ceylon.

Darien, shown in fig. 12, under the direction of Commander Selfridge, U.S.N.; and *second*, that of Nicaragua, also shown in fig. 12, under the direction of Commander Lull, U.S.N. To both of these expeditions were attached a large staff, including naval officers, civil engineers, surveyors, mineralogists, &c., and their surveys appear to have extended over the years 1871, 1872, and 1873.

Proposed Darien Canal. The results of these surveys are thus summarized in the report of the Secretary to the Navy, submitted to the Government of the United States in 1873, from which we take the following information. Of the Darien route, it is said that it includes 100 miles of navigation of the River Atrato, which has been carefully sounded, and found to be fully capable of being navigated by the largest class of ocean-steamers. Between Atrato and the Pacific a canal or artificial cut must be formed of 28 miles in length. The canal for 22 miles of this distance passes through a plain having a gradual rise of 90 feet. There will then remain 6 miles to the Pacific, three of which will be in moderate open cutting, and 3 miles will be tunneling. It is estimated that the work will cost between £10,400,000 and £12,600,000, and that it can be completed in ten years. The tunnel, being for the passage of ships of the largest size, is proposed to be 112 feet high and 60 feet wide, and is to have 87 feet of clear headway above the surface of the water. The canal is to be 25 feet in depth, with a bottom width of 50 feet, and a surface width of 70 feet. The locks, twenty in number, are to be 427 feet long, 54 feet wide, with a lift of 10 feet. The water supply is to be derived from the Napipi river, and the gaugings and observations made on evaporation lead to the conclusion that there is a great excess of water above the supply required for the canal. Commander Selfridge gives two alternative schemes, by which the tunneling is increased in length and the number of the locks diminished, at an estimated cost of from £17,000,000 to £18,000,000 respectively.

The exploration of the Nicaraguan route, under Commander Lull, the position of which is also shown in fig 12, is said to have proved the existence of a practicable route, having Lake Nicaragua as its summit-level, being 107 feet above mean tide. It is proposed by this route to connect the lake with the Pacific by a canal 16·3 miles in length, beginning at the mouth of the Rio del Medio and terminating at Brito. The first 7·5 miles will require an excavation averaging 54 feet in depth, and will be the most expensive part of the whole work. Ten locks and one tide-lock will be required between the lake and the sea. There will be 56 miles of lake navigation. Proposed Nicaragua Canal.

Slack-water navigation in the San Juan from its head to the mouth of San Carlos is considered perfectly feasible, and it is proposed to improve the river by four dams, at Castillo Rapids, Balas Rapids, Machuca Rapids, and at the mouth of the San Carlos River, at all of which places there are excellent sites for dams. A short section of canal will

one lock will be required to get around each of the upper three dams. From the fourth dam to Greytown in the Caribbean Sea an independent canal will be required 41·9 miles in length with seven locks, which apparently presents no difficulty. The total length of the proposed canal is 61·7 miles, and no tunnel is required. The harbour of Greytown has been partially destroyed by a silt which comes from the San Carlos, and others of the lower tributaries of the San Juan, and the branch of the river leading to Greytown has become so much filled up that it is now, at the lowest stage of the water, only 324 feet wide and 6 inches deep at the fork. It is proposed to shut off this branch entirely and send all the silt-bearing water through the Colorado mouth, which empties into the sea 18 miles from Greytown, and to admit to the harbour only the water of the canal, which, being drawn from the main river above the mouth of the San Carlos, will be perfectly clean. The harbour then cleared out, will leave nothing to deteriorate it again.

Short breakwaters will be required to protect the entrances from the surf, both of which are included in the estimate for the work.

Careful gauging at the lowest stage shows that Lake Nicaragua, which has a surface area of 2700 square miles, and a drainage area of 8000 square miles, will supply thirty-eight times the maximum possible demand of water.

The depth of water is to be 26 feet, the width at bottom 72 feet, and at surface 150 feet. The locks, twenty-one in

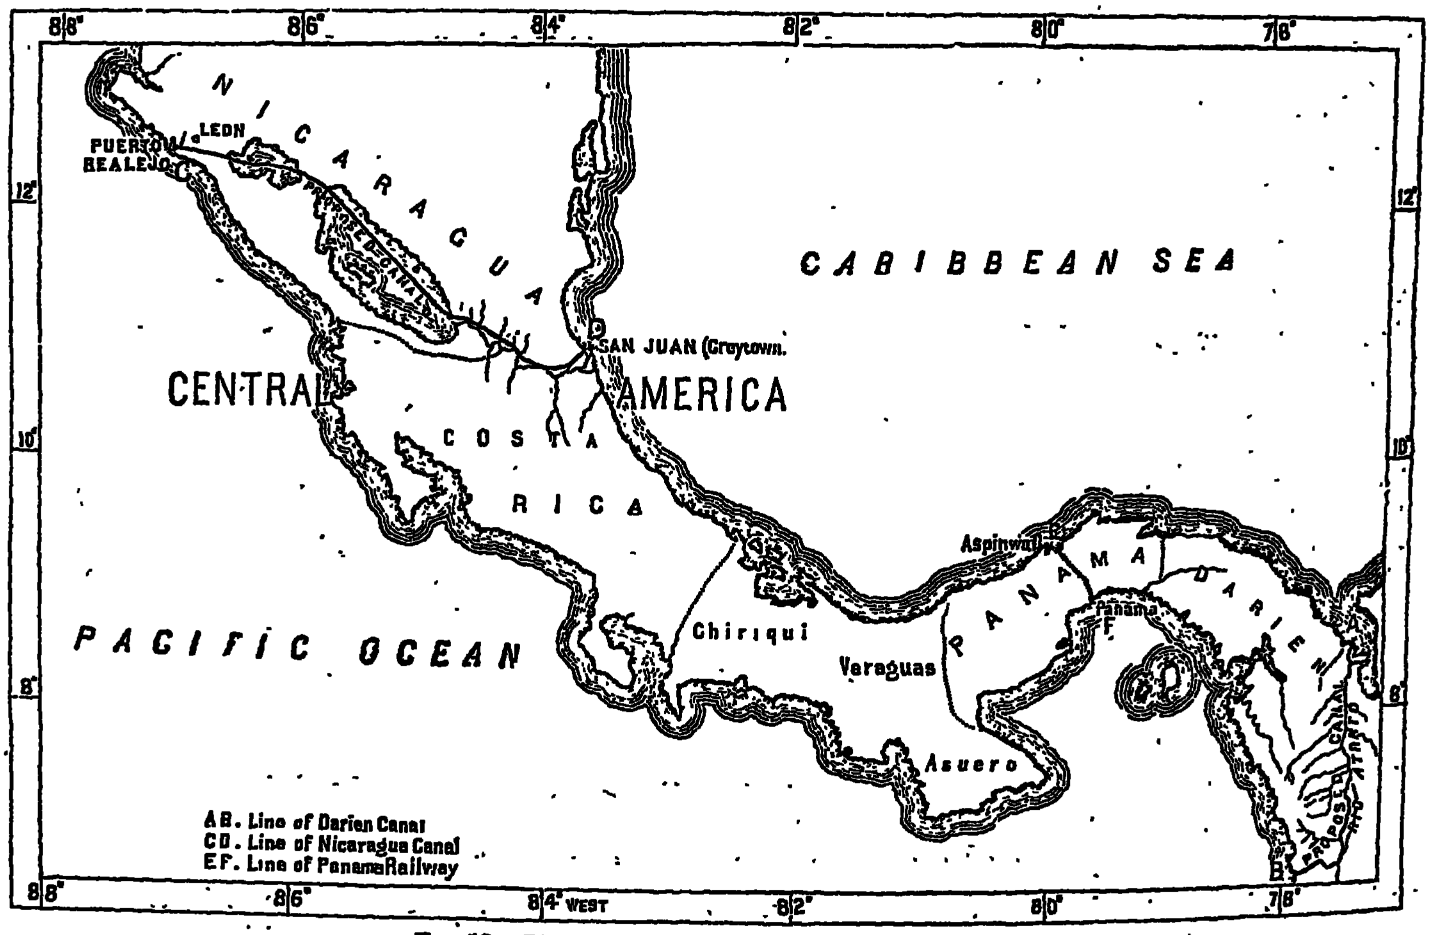

FIG. 12.—Lines of proposed Darien and Nicaragua Canals.

number, with a lift of from 8 to 10 feet, are to be 400 feet long and 72 feet wide. The estimate is stated at £15,900,000.

M. Lesseps, in a lecture on the Suez Canal, delivered before the Société des Gens de Lettres at Paris, has given it as his opinion that unless the Atlantic and Pacific can be united by simply piercing the Isthmus from sea to sea without locks, as at the Suez Canal, the proposed scheme cannot possibly succeed as a commercial enterprise, because of the inadequacy of a canal with locks to pass the traffic that will frequent it, and also of the uncertainty of sufficient water to supply the lockage and evaporation. This latter objection, however, seems to be disproved by the researches of the American engineers who have investigated the subject. A further difficulty arises in maintaining a sufficient sea-water depth to the canal even after it has been formed. On this point the writer of this article, judging from documents prepared under the sanction of the Government of the United States and submitted to him by an authorized official of the Government, arrived at the conclusion that there are very formidable obstacles to the establishment and future maintenance of a deep-water entrance to the proposed Nicaraguan Canal at Greytown, in the Caribbean sea. These obstacles involve the engineering problem of maintaining permanent deep water through an extensive shallow foreshore composed of soft materials and exposed to heavy seas. The reports state "that at Greytown there are now islands where twenty years ago there was water enough to float a frigate." It remains to be seen whether the same difficulties apply to the entrance to the proposed Darien scheme; and, to show that such fears may not be unfounded, we may remind the reader that the difficulties exist, as we have stated, at the Mediterranean entrance to the Suez Canal.

The question as to the best route for transit between the Atlantic and Pacific is, it will be seen, still far from being solved, but the necessity for free access from sea to sea remains an acknowledged fact. Its importance, especially to the United States, but in some degree to all the world, is such that, great as are the engineering difficulties, this long-cherished bold *idea* may yet become a stupendous *reality*. (D. S.)

CANAL, or CANALETTO, ANTONIO (1697–1768), a Venetian painter, born 18th October 1697, was bred with his father, a scene-painter at Venice, and for some time followed his father's line of art. In 1719 he went to Rome, where he employed himself chiefly in delineating ancient ruins, and particularly studied effects of light and shade, in which he became an adept. He was the first painter who made practical use of the camera lucida. On returning home he devoted his powers to views in his native city, which he painted with a clear and firm touch and the most facile mastery of colour in a deep tone, introducing groups of figures with much effect. In his latter days he resided some time in England. His pictures, in their particular range, still remain unrivalled. He died on 20th August 1768. Bellotto (commonly named Bernardo) Canaletto, 1724–1780, was his nephew and pupil, and painted with deceptive resemblance to the style of the more celebrated master.

CANANDAIGUA, a town in the United States, capital of the county of Ontario in New York, is situated at the northern end of a lake of the same name, 29 miles S.E. of Rochester by rail, in 42° 54′ N. lat. and 77° 27′ W. long. It is a railway junction of some importance, and has a court-house, an academy, and two printing-offices. Its incorporation dates from 1815. The lake is a beautiful sheet of water about 15 miles long, with a breadth varying from less than a mile to more than a mile and a half. It is about 437 feet above Lake Ontario. The population of the town is 4862, and of the township 7274.

CANANORE. See KANANORE.

CANARA. See KANARA.

CANARY (*Fringilla canaria*), a well-known species of Conirostral Bird, belonging to the family *Fringillidæ* or Finches. It is a native of the Canary Islands and Madeira, where it occurs abundantly in the wild state, and is of a greyish-brown colour, slightly varied with brighter hues, although never attaining the beautiful plumage of the domestic bird. It was first domesticated in Italy during the 16th century, and soon spread over Europe, where it is now the most common of cage-birds. During the 350 years of its domestication, the canary has been the subject of careful artificial selection and of crossing with allied species, the result being the production of a bird differing widely in the colour of its plumage, and in a few of its varieties even in size and form, from the original wild species. The prevailing colour of the most admired varieties of the canary is yellow, approaching in some cases to orange, and in others to white; while the most robust birds are those which, in the dusky green of the upper surface of their plumage, show a distinct approach to the wild forms. The least prized are those in which the plumage is irregularly spotted and speckled. In one of the most esteemed varieties, the wing and tail feathers are at first black—a peculiarity, however, which disappears after the first moulting. Size and form have also been modified by domestication, the wild canary being not more than 5½ inches in length, while a well-known Belgian variety usually measures 8 inches. There are also hooped or bowed canaries, feather-footed forms, and top-knots, the latter having a distinct crest on the head; but the offspring of two such top-knotted canaries, instead of showing an increased development of crest, as might be expected, are invariably bald on the crown. Most of the varieties, however, of which no fewer than twenty-seven were recognized by French breeders so early as the beginning of last century, differ merely in the colour and the markings of the plumage. Hybrids are also common, the canary breeding freely with the siskin, goldfinch, citril, greenfinch, and linnet. Some of the hybrids thus produced, are, according to Darwin, almost completely fertile, but they do not seem to have given rise to any distinct breed. It is the female canary which is almost invariably employed in crossing, as it is difficult, if not impossible, to get the females of the allied species to sit on the artificial nests used by breeders. In a state of nature canaries pair, but under domestication the male bird has been rendered polygamous, being often put with four or five females; still he is said to show a distinct preference for the female with which he was first mated. It is from the others, however, that the best birds are usually obtained. The canary is very prolific, producing eggs, not exceeding six in number, three or four times a year; and in a state of nature it is said to breed still oftener. The work of building the nest, and of incubation, falls chiefly on the female, while the duty of feeding the young rests mainly with the cock bird. The natural song of the canary is loud and clear; and in their native groves the males, especially during the pairing season, pour forth their song with such ardour as sometimes to burst the delicate vessels of the throat. The males appear to compete with each other in the brilliancy of their melody, in order to attract the females, which, according to Bechstein, always select the best singers for their mates. The canary readily imitates the notes of other birds, and in Germany and especially Tyrol, where the breeding of canaries gives employment to a large number of people, they are usually placed for this purpose beside the nightingale. In England they are taught in a similar way to imitate the woodlark. They are also taught to whistle one or two airs, and even to articulate a few words. The female possesses considerable vocal powers, but her notes are weaker than the male's, and her song usually less consecutive.

CANARY ISLANDS, THE, lie in the North Atlantic Ocean, between the parallels of 27° 4′ and 29° 3′ N. lat., and the meridians of 13° 3′ and 18° 2′ W. long. The seven principal islands cover an area of 3256 English sq. miles, and had a population of 237,036 in 1860:—

	Teneriffe.	Grand Canary.	Palma.	Lanzarote.	Fuerteventura.	Gomera.	Hierro
Area.........	877·7	758·3	718·5	323·5	325·1	169·7	82·2
Population,	93,709	68,970	31,135	15,837	10,936	11,350	5026

Fuerteventura lies nearest to the African coast, the interval being between 50 and 60 miles. Besides these there are many islets, most of which are uninhabited.

History.—There is ground for supposing that the Phœnicians were not ignorant of the Canaries. The Romans, in the time of Augustus, received intelligence of them through Juba, king of Mauritania, whose account has been transmitted to us by the elder Pliny. He mentions "Canaria, so called from the multitude of dogs of great size," and "Nivaria, taking its name from perpetual snow, and covered with clouds," doubtless Teneriffe. Canaria was said to abound in palms and pine trees. Both Plutarch and Ptolemy speak of the Fortunate Islands, but their description is so imperfect that it is not clear whether the Madeiras or the Canaries are referred to. There is no farther mention of them until we read of their rediscovery about 1334, by a French vessel driven amongst them by a storm. A Spanish nobleman thereupon obtained a grant of them, with the title of king, from Clement VI., but want of means prevented him from carrying out his project of conquest. Two expeditions subsequently set out from Spanish ports, and returned without having taken possession. At length three vessels, equipped by Jean de Béthencourt, a gentleman of Normandy, sailed from Rochelle in 1402, and bent their course to the Canaries. He landed at Lanzarote and Fuerteventura, but being opposed by the natives, and finding himself deficient in means to effect his purpose, he repaired to the court of Castile, and obtained from Henry III a grant of the islands, with the title of

king, he sailed in 1404 with a strong force, which mastered Lanzarote, Fuerteventura, Gomera, and Hierro, without bloodshed. Being repulsed in his attempts on Palma and Canary, he returned to Europe in 1408 to obtain further assistance. He was well received at the Castilian court, where he was promised aid; but he died shortly afterwards in France. Bethencourt's nephew had been left governor of the islands, and claimed to succeed to his uncle's rights. Being charged with many acts of misgovernment, he went to Spain to clear himself, and whilst there sold his rights to Don Enrique de Guzman, who, after expending large sums in fruitless endeavours to reduce the unconquered islands, sold them to another Spaniard named Paraza. His successors, about 1461, took nominal possession of Canary and Teneriffe, but the natives effectually resisted their occupation of them. Meantime it appeared that Jean de Bethencourt's nephew had fraudulently made a second sale of the islands to Portugal, and the difference thus arising between the crowns of Spain and Portugal was ended by the cession of the islands to the former. Grand Canary, Teneriffe, and Palma remaining unsubdued in 1476, Ferdinand and Isabella of Spain compelled Paraza's successors to sell those islands to the crown; and the following year 1000 men were despatched to reduce them. After much bloodshed, and with reinforcements from the mother country, the Spaniards, under Pedro de Vera, became masters of Grand Canary in 1483. Palma was conquered in 1491, and Teneriffe in 1495, by Alonzo de Lugo. All the islands still continue in the possession of Spain.

Inhabitants.—As to the derivation of their original inhabitants, the Guanches, nothing certain is known. The most probable supposition is that they came from the adjoining coast of Africa. Pliny states that the islands were uninhabited at the time of which he wrote. If this were so, we might infer, from the absence of any trace of Mahometanism amongst the people found there by the Spaniards, that the migration took place between the time to which his account refers and the time of the conquest of Barbary by the Arabs. Many of the Guanches fell in opposing the Spanish invasion, many were sold by the conquerors as slaves, and many conformed to the Roman Catholic faith and intermarried with the Spaniards,—so that all trace of them as a distinct race is lost. They were said to be of tall stature, and Humboldt styles them the Patagonians of the Old World; but the skeletons of Guanches when measured have been found to be less than average skeletons of Europeans. The Guanches embalmed the bodies of their dead, and placed them in caves; and many mummies have been found at different times in a state of extreme desiccation, each weighing not more than 6 or 7 lb. Two inaccessible caves in a vertical rock by the shore, three miles from Santa Cruz (Teneriffe), are said still to contain bones. A few words of the languages spoken by the ancient inhabitants have been preserved, and a resemblance of some of them to words of North African dialects has been noticed. On the other hand, the Guanches had customs, such as that of preserving their dead, in which they differed from the Berbers. Councillor Von Löher, one of the most recent investigators of the question, finds that the names of places in the interior of the island are generally either of Berber or of Teutonic origin, and maintains that the Guanches were in all probability the descendants of Vandal and Gothic immigrants.

The present inhabitants are slightly darker than the people of Spain, but in other respects are scarcely distinguishable. The men are of middle height, well-made, and strong; the women are not striking in respect of beauty, but they have good eyes and hair. Spanish is the only language in use. The people have most of the traits of the people of the peninsula; they are sober, but given to gambling; they are quick, but lazy, faithless, and superstitious. The lower orders are quite illiterate, and the better classes not very enlightened. A few booksellers' shops of a minor description exist at Santa Cruz and Las Palmas. The sustenance of the lower classes is chiefly composed of fish, potatoes, and *gofio*, which is merely Indian corn or wheat roasted and then, when ground, kneaded with water or milk.

Government, &c.—The Archipelago is politically considered part of the province of Andalusia. The governor-general, who resides at Santa Cruz, has chief command both in civil and military affairs. The actual administration of affairs is in the hands of two lieutenant-governors, who reside at Santa Cruz and Las Palmas. On the other islands are deputy-governors, acting under the lieutenant-governor to whose district they belong. The military force is composed of a battalion of soldiers of the line, numbering about 1000 men; six regiments of militia, amounting to about 8000 men, distributed amongst the islands; and a few companies of artillery. There is a military commander on each island. The great court of appeal sits at Las Palmas. Courts of first instance sit at Santa Cruz, Orotava, and Las Palmas. The land in great part is strictly entailed. The islands form two bishoprics, Teneriffe and Grand Canary. The whole ecclesiastical revenue is estimated at upwards of £36,000. The monkish establishments have been suppressed, and such of the monasteries and convents as are not kept up for secular purposes are falling to ruin. No form of religion except the Roman Catholic is tolerated.

Climate and Meteorology.—From April to October a north or north-east wind of more or less strength blows upon the islands, commencing at 10 A.M. and continuing until 5 or 6 P.M. In summer this wind produces a dense stratum of sea cloud (cumuloni), 1000 feet thick, whose lower surface is about 3500 feet above the sea at Teneriffe. This does not reach up to the mountains, which have on every side a stratum of their own, about 500 feet thick, the lower surface being about 2500 feet above the level of the sea. Between these two distinct strata there is a gap through which persons on a vessel approaching or leaving the island may obtain a glimpse of the peak. Travellers who ascend the mountains look down on these stationary layers of cloud. The sea cloud conceals from view the other islands, except those whose mountains pierce through it. On the south-west coasts there is no regular sea or land breeze. In winter they are occasionally visited by a hot south-east wind, called Levante, from the African continent, producing various disagreeable consequences on the exposed parts of the person, besides injuring the vegetation, especially on the higher grounds. Locusts have sometimes been brought by this wind. In 1812 it is said that locusts covered some fields in Fuerteventura to the depth of 4 feet. Hurricanes, accompanied by waterspouts, sometimes cause much devastation; but, on the whole, these islands are singularly free from such visitations. The climate generally is mild, dry, and salubrious. On the lower grounds the temperature is equable, the daily range seldom exceeding 6° Fahr. The rainy season occurs at the same period as in southern Europe. The dry season is at the time of the trade-winds, which extend a few degrees farther north than this latitude. "In no part of the world is the barometer more susceptible of atmospheric changes than amongst the Canary Islands. A rapid rise is the sure precursor of an easterly wind, whilst the contrary as certainly indicates a change to west or south-west" (Lieut. Arlett).

Agriculture, Manufactures, and Commerce.—In ordinary years sufficient grain and potatoes are produced to supply the wants of the islands. The soil on the lower part of the islands, where water is plentiful, is productive; in some places two crops of Indian corn and one of potatoes

can be obtained from the same piece of ground in a twelvemonth. Except at Fuerteventura, the vine is much cultivated, but chiefly at Teneriffe, the best wines being produced on the north-west coast. None, however, is considered so good as the wine of Madeira. The most esteemed kind is sent to England under the name of Vidonia. The grape disease made its appearance at the Canaries in 1853, and destroyed nearly the whole crop. Previously the total annual produce was estimated at about 40,000 pipes, of which 25,000 pipes were produced in Teneriffe. Between 8000 and 9000 pipes were exported. The price per pipe on board ranged from £8 to £20. Some of the wine is distilled into good brandy. Sumach, canary-seed, and a little flax are grown. Sweet potatoes, maize, gourds, pumpkins, tara (*Colocasia antiquorum*), lentils, *Cicer arietinum*, beans, kidney beans, and lupines are extensively cultivated for food. From bad management the fruits are generally inferior. They include oranges, figs, bananas, dates, pineapples, pomegranates, papaws, guavas, custard apples, and prickly pears. There are no cocoa-nut trees or bread-fruit trees. A little oil is obtained from the olive in Grand Canary. The agave is abundant, and supplies a material for ropes, girths, &c. The leaves of the date palm are made into hats and baskets. A good deal of orchil-lichen is gathered for exportation; and the ice-plant is grown in small quantity for barilla. The sugar manufacture, once largely carried on, has fallen before the American and West Indian trade; the only two existing mills are on Palma. Wine having been for some time so little remunerative, other products have received attention, the chief being cochineal. This insect, which feeds on a species of cactus, was introduced in 1825, and is now largely produced on all the islands,—land formerly occupied by grain and vines being devoted to its cultivation. In 1873 upwards of 5,728,000 lb, of the total value of 13,894,225 pesetas, or about £555,849, were exported, principally to France and England. The silkworm is reared to a small extent, chiefly on Palma. Raw silk is exported, and some is manufactured on the spot into stockings, ribands, &c. Some linen and woollen stuffs of a coarse kind are made for home consumption, but the great bulk of the clothing in use is of British manufacture. The island goats (a peculiar and esteemed breed) furnish milk, from which butter and cheese are made. Pigs and sheep of a small coarse-woolled breed are numerous. Horses and cattle are scarce; domestic fowls and rabbits are plentiful. Asses and mules are much used. A fishery on the African coast, which gives employment to many persons, has existed from an early period. The fish, principally bream, is salted and largely consumed at the Canaries.

There is a good deal of intercourse by means of boats and small sailing vessels amongst the different islands. In this way wine, raw silk, cochineal, barilla, and dried fruits are taken to the places of export; and grain is conveyed from those islands where it is abundant to those where the supply is deficient. The principal foreign trade is with England, the chief articles of export being wine, cochineal, barilla, and orchil. The imports consist of iron, metal goods, glass, crockery, leather, and silk, cotton, and woollen manufactures. There is also a considerable trade with the United States and the countries bordering the Mediterranean. With Hamburg and France an exchange of commodities takes place. The ships employed in this commerce are foreign, chiefly British; but the islanders send a few vessels of their own with brandy, coarse earthenware, and silk goods to the Spanish West Indies, bringing back cigars, sugar, coffee, rum, cocoa (the material of chocolate), and a few other articles. Santa Cruz, Orotava, and Las Palmas are the only ports engaged in foreign trade; nearly 300 vessels enter these ports in the course of a year. In 1852 the ports were practically made free—the small duty of 2s. per cent. only being now levied upon imported goods, with the exception of tobacco, which pays 5d. per lb., and cigars which pay 10d. per lb. Spanish steamers ply between Cadiz and Santa Cruz. The Spanish Government packet on its outward voyage to Havana touches at Santa Cruz once a month; and the same port is visited by the English mail steamers in their voyages to and from the African coast.

Zoology.—The indigenous mammals and reptiles of the Canary Islands are very few in number. Of the former, only species of dog, of swine, of goat, and of sheep were found upon the island by the Spanish conquerors. The race of large dogs which is supposed to have given a name to Canary has been long extinct. A single skeleton has been found, which is deposited in one of the museums at Paris. The ferret, rabbit, cat, rat, mouse, and two kinds of bat have become naturalized. The ornithology is more interesting, on account at once of the birds native to the islands and the stragglers from the African coast. The latter are chiefly brought over in winter when the wind has blown for some time from the east. Among the former are some birds of prey, as the African vulture, the falcon, the buzzard, the sparrow-hawk, and the kite. There are also two species of owl, three species of sea-mew, the stockdove, quail, raven, magpie, chaffinch, goldfinch, blackcap, canary bird, titmouse, blackbird, house-swallow, &c. The bird with the sweetest song is a variety of the blackcap or *Sylvia atricapilla*. As to the insects, mention may be made of a species of gnat or mosquito which is sometimes troublesome, especially to strangers, and the cockroach. The list of reptiles is limited to three lizards and a frog. The only fresh-water fish is the eel. The marine fishes are not numerous, the reason perhaps being that the steepness of the coast does not allow seaweed to grow in sufficient quantity to support the lower forms of marine animal life. Whales and seals are occasionally seen. The cuttle-fish is abundant, and is sought for as an article of food.

Botany.—The position of mountainous islands like the Canaries, in the sub-tropical division of the temperate zone, is highly favourable to the development, within a small space, of plants characteristic of both warm and cold climates. Von Buch refers to five regions of vegetation in Teneriffe:—1. From the sea to the height of 1300 feet. This he styles the African region. The climate in the hottest parts is similar to that of Egypt and southern Barbary. Here grow, among the introduced plants, the coffee-tree, the date-palm, the sugar-cane, the banana, the orange tree, the American agave, and two species of cactus, and among indigenous plants, the dragon tree on the north-west of Teneriffe. A leafless and fantastic euphorbia, *E. canariensis*, and a shrubby composite plant, *Cacalia Kleinia*, give a character to the landscape about Santa Cruz. 2. Between 1300 feet and 2800 feet. This is the region of South European vegetation, the climate answering to that of southern France and central Italy. Here flourish the vine and the cereals. 3. The region of indigenous trees, including various species of laurel, an *Ardisia*, *Ilex*, *Rhamnus*, *Olea*, *Myrica*, and other trees found wild also at Madeira. The clouds rest on this region during the day, and by their humidity support a vegetation amongst the trees, partly of shrubs, and partly of ferns. It extends to the height of 4000 feet. 4. The region of the beautiful *Pinus canariensis*, extending to the height of 6400 feet; here the broad-leaved trees have ceased to grow, but arborescent heaths are found throughout its whole extent, and specimens of *Juniperus oxycedrus* may be met with. 5. The region of Retama (*Cytisus nubigenus*), a species of white-flowering and sweet-scented broom, which is found as high as 11,000 feet. At the upper edge of this region a [illegible]

violet clings to the soil, and above there is nothing but a little lichen. The number of wild flowering plants may be estimated at 900, upwards of 270 of which are peculiar to the Canaries. The forms of vegetation must in the main be considered North African, since the origin of many of those which they have in common with Southern Europe should be looked for in Africa. The character of the vegetation in Lanzarote and Fuerteventura islands, composed of extensive plains and low hills, with few springs, is different from that of the other islands, which are more elevated and have many springs. The wood is more abundant, and the vegetation more luxuriant.

Geology.—Recent soundings have proved that the Canary Islands, like the other island groups of the North Atlantic, are the summits of mountains that are surrounded by an ocean of great depth. The lower and exterior portion of these islands consists for the most part of basalt, compact, vesicular, or scoriaceous, interstratified with beds of variously-coloured tufa. The compact variety of basalt frequently contains scattered grains and crystals of augite and olivine. In some cases the rock is chiefly trachyte. In Grand Canary the fossils contained in the tufas prove that movements of elevation began in the Upper Miocene period. They continued down to the Pleistocene period, for raised beaches containing shells of the recent period exist both in Teneriffe and Grand Canary. Simultaneously with the upheaval subaërial eruptions were taking place. Many of the superimposed streams of lava are divided from one another by red bands of *laterite*, probably ancient soils formed by the decomposition of the surfaces of the lava, and showing that the building up of the islands was a slow process. In Teneriffe the basalt and tufa form an exterior mass, through which in the centre emerge the felspathic or trachytic rocks forming the nucleus of the volcanic cone, and over them fragments of pumice and streams of modern lava have been thrown. These trachytic rocks contain numerous disseminated crystals of glassy felspar. Obsidian is found in several parts of Teneriffe, and is usually spotted with white crystals of felspar. The few minerals that have been found in the Canary Islands are those characteristic of volcanic regions. A little iron exists, but is not turned to account. In no part of Teneriffe has there been discovered any sedimentary rock. The old lavas in Lanzarote are covered by a thin layer of white concretionary limestone, the origin of which is obscure. In Grand Canary and Fuerteventura there is also calcareous stone, but its nature does not appear to be known.

[Te]neriffe. TENERIFFE, the largest island of the group, lies between Grand Canary and Gomera. It is of irregular shape, 60 miles in length, with an extreme breadth of 30 miles. Not more than one-seventh is cultivable. A chain of mountains traverses the island in the direction of its greatest length, and in the middle of the broadest part rises the celebrated Peak, locally known as the Pico de Teyde, which, with its supports and spurs, occupies nearly two-thirds of the whole island. It has a double top; the highest point, El Piton, is 12,200 feet above the sea; the other, Chahorra, connected with the first by a short narrow ridge, has a height of 9880 feet. They are both orifices in the same grand dome of trachyte. Neither reaches the line of perpetual snow. There is, however, a natural cavern, 11,050 feet above the sea, where snow is preserved all the year. Snow remains about four months on the upper part of the Peak.

For more than one-half of its circumference the base of the true peak rises from an elevated but comparatively level tract, called by the Spaniards *El Llano de la Retama* (*retama* being the name of the *Cytisus nubigenus* which abounds there), and by the English the Pumice-Stone Plains. On the south-east, south, and south-west there is a high curved ridge overlooking the Pumice-Stone Plains, and presenting a very steep face to the Peak. This is the analogue of the Somma ridge of Vesuvius. Between the ridge and the sea the slope is more gradual, and there are intervening table-lands. A path used by the country people in going from one side of the island to the other crosses this ridge at the height of 8000 feet. Peaks rise from the ridge, one of which (*Guajara*) attains the height of 8900 feet. This ridge (the Llano) and the modern volcanic cone resemble in aspect a fortress with circular ramparts and a fosse. The ramparts are about 8 miles in diameter, and tower in some places more than 1500 feet above the fosse. They consist, as shown in the sections, of beds of trachyte, greenstone, and tufa of various thicknesses, and intersected by dykes and faults. On the north-west comparatively late eruptions have filled up the fosse. The modern cone, then, is a pile of lava, pumice, and ashes, thrown up in an ancient crater which had become greatly enlarged either by a falling in of the upper part of the cone, or by a series of violent explosions. Both El Piton and Chahorra have craters on their summits, from which issue steam and a little sulphureous vapour. The crater on El Piton is partly surrounded by a wall of lava, which has been made white by the action of sulphureous vapours, and every crevice contains small crystals of sulphur. The thermometer rises considerably when thrust into the ground. The crater is about 300 feet across, with a depth of 70 feet. The average slope of the lower part of the cone is 28°; that of the sugar loaf at the top is 33°. The crater on Chahorra has a diameter of 4000 feet; its depth is scarcely 150 feet. The view from the highest point, when no clouds intervene, is very extensive. All the islands of the Archipelago are visible, and the horizon is 140 miles distant. Neither the coast of Africa nor the island of Madeira is within the range of vision.

The ascent of the Peak is usually made from Orotava, on the northern side of the island. After the cultivated grounds are left, the region of arborescent heaths is crossed. This zone extends over the zones of laurels and pines which have here disappeared. Above this is a belt covered with *codeso* (*Adenocarpus frankenioides*), and this extends to the region of *retama*; the first bushes of which are met with at the pass which admits the traveller into the *Llano de la Retama*. The scenery here is in striking contrast with what it has previously been. Instead of a steep and rugged ascent among black basaltic rocks, the traveller enters upon gently sloping ground, covered to a considerable depth with white pumice gravel, amongst which spring bushes of retama. The tender shoots of this shrub serve the wild goats for food, and the flowers yield a rich honey to the bees. The entrance to the Llano at a sort of portal (called Portillo) between two basaltic hills, is about 7000 feet above the sea. Between two and three hours are consumed in crossing the Llano to the base of the cone, the lower part of which (*Monton de Trigo*) is ascended to a point 9750 feet above the sea, called *Estancia de los Ingleses*, where the mules are usually left, and where travellers frequently pass the night. Then comes the Malpays, 1000 feet in altitude, consisting of rough black lava streams broken up into blocks and stones. These cease at the neck called Rambleta, the lip of an older crater over which the lava poured before the sugar-loaf cone of pumice and ashes was thrown up. The pumice is in such quantity that at a distance it has the appearance of snow coating the Peak. From twenty to twenty-four hours are consumed in ascending the Peak and returning to Orotava.

To the north-west of the grand cone some thousands of feet below Chahorra, there are many small cones of eruption, showing that the intensity of volcanic action was greatest on this side. Eastward from the ridge bounding the Pumice-Stone Plains extends a chain of mountains to

the north-eastern extremity of the island. The highest peaks are Izana (7374 feet), Perejil (6027), and Cuchillo (5467).

We have no account in history of eruptions from either crater of the Peak. In 1795 a great quantity of lava was poured out from three vents on the eastern side; and in the same year lava streams issued from a crater near Guimar, half-way between Santa Cruz and the Peak. In the year 1706, a vent on the north-western side of the Peak discharged a copious stream, which flowed down to the sea, and nearly filled up the harbour of Garachico. For three months in 1798 much lava and other volcanic matter were ejected from orifices to the west of Chahorra.

Santa Cruz de Santiago, on the south coast, is the residence of the governor-general of the Canaries, the civil lieutenant-governor of the Teneriffe district, and the military governor of the island. Its position is 28° 28′ 30″ N. lat. and 16° 16′ W. long. It is a well-built and tolerably clean town of 10,830 inhabitants, lying on a small plain bounded by bare and rugged volcanic rocks, amongst which lie narrow valleys called *barrancos*. Scarcely any vegetation, except thorny cactuses and euphorbias, is to be seen in the neighbourhood. The streets are at right angles to each other, narrow, but provided with side walks. There are three public squares. The houses are generally low, with flat roofs; those of the better class are large, with a court-yard in the middle, planted with shrubs in the Spanish fashion. The market is well supplied with meat, fruits, and vegetables. Good water is brought from the fine forest of Mercedes, which is composed of laurels and other indigenous trees. A British consul resides in the town, and several English families. The accommodation for strangers is neither plentiful nor good. The Spanish cloak is much worn by the men, and the white mantilla by the women. Dromedaries brought from Lanzarote and Fuerteventura are in use for the conveyance of merchandise and in agricultural operations. A good animal costs from 30 to 40 dollars. A few wheel-carriages are in use. Much ground in the neighbourhood is planted with cactus (*Opuntia Tuna*) for the support of the cochineal insect. The town is defended by several batteries; and it was by a shot from one of these that Lord Nelson lost his arm, when he unsuccessfully attacked the place in 1797. Some English flags lost on that occasion are still hanging in one of the churches. The anchorage is good, and a mole facilitates landing. About 200 vessels annually visit the port. The climate is dry and moderately warm, the annual mean being 71° Fahr. The mean of the coldest month is 63°·8 Fahr., and of the hottest 78°·8 Fahr. Rain falls on an average on thirty-six days in the year.

Laguna (population 4645) stands at the distance of four miles from Santa Cruz, in the centre of a plain where much grain is produced, elevated 1725 feet above the sea, and nearly surrounded by mountains. The situation is beautiful, but the town itself is gloomy. It contains several deserted convents and a cathedral. In summer the temperature is refreshingly cool, and for that reason Laguna is then resorted to by the rich of Santa Cruz. In winter it is cold and damp, the plain being frequently laid under water by rain. This is in consequence of three aerial currents meeting there, from the north, east, and south-west. The mean temperature of the year is 63°·2 Fahr. Snow has never been known to fall here. The humidity of the atmosphere is shown by the quantities of sempervivum growing on the houses and walls.

A good road connects Santa Cruz and Orotava, a town on the north coast 25 miles distant. It passes through Laguna and Matanza,—a place deriving its name from the overthrow of the invading Spaniards by the Guanches in 1494. All travellers speak in terms of warm admiration of the scenery in this part of the island. Humboldt says he "never beheld a prospect more varied, more attractive, more harmonious in the distribution of the masses of verdure and of rocks, than the western coast of Teneriffe." Date palms form a striking feature in the landscapes. The town of *Orotava* (population 3228) is 1040 feet above the sea. The houses are solidly built, but it has a deserted aspect. A stream of water is conducted through every street. The famous dragon-tree, which so many travellers have described, was lately destroyed by a storm. *Port Orotava*, three miles from the town, is a clean place, with between 4000 and 5000 inhabitants, amongst whom are three or four English families. The streets are broad and the houses well built. The roadstead, protected by a fort and some batteries, affords little or no shelter against wind. The botanic garden, founded by a patriotic Spanish nobleman, is now in the hands of a market-gardener. At *Icod de los Vinos*, a pretty town of 4000 inhabitants, farther to the west, in a fertile district, is a dragon-tree, the largest now existing in the island. The stem near the ground has a circumference of 38 feet, and its height is upwards of 60 feet. Near the town is an immense cavern, in which many Guanche bones are to be seen. There are several other towns of less importance, principally in the north-west, not far from the coast. The highest inhabited place is Chasna, on a plain more than 4000 feet above the sea, to the south of the Peak.

Grand Canary

GRAND CANARY (*Gran Canaria*), the most fertile island of the group, is nearly circular in shape, with a diameter of 24 miles and a circumference of 75 miles. The interior is a mass of mountain, reaching to the height of about 6000 feet above the sea, with ravines radiating to the shore. Its highest peak, Los Pexos, is 6400 feet above the sea. Large tracts are covered with native pine (*P. canariensis*). There are several mineral springs on the island. From the nature of the ground only a small part is under cultivation. *Las Palmas* (population 12,572), the seat of the local Government, is a well-built and clean town on a small bay on the north coast, deriving its name from the numerous palm trees. It contains a handsome cathedral, a hospital, a college, several secularized convents, and an alameda or public walk. Its climate is more humid than that of Santa Cruz. Water is brought into the principal streets and squares by an aqueduct. The harbour, Puerto de la Luz, is defended by several *forts*, and affords good anchorage and shelter against all winds except the south-east. A British vice-consul resides here. In 1851 the cholera visited the island, and 9000 persons died, whilst not a single case occurred on any other island. *Telde*, the second place in the island, stands on a plain, surrounded by palm trees. At *Atalaya*, a short distance from Las Palmas, the making of earthenware vessels employ some hundreds of people, who inhabit holes made in the tufa.

Palma

PALMA (correctly, San Miguel de la Palma), 26 miles long, with an extreme breadth of 16 miles, lies 67 miles W.N.W. of Teneriffe. It is traversed in its longest direction (north to south) by a chain of mountains, the highest of which is 7900 feet above the sea. At the broadest part is a crater nine miles in diameter, known as the Caldera (*i.e.*, cauldron), from which, on its south-west side, runs a ravine to the sea. The bottom of the crater has an elevation above the sea of 2300 feet, and it is overhung by peaks that rise more than 5000 feet above it. Some of these peaks are covered with snow for several months in the year. Extensive woods, principally composed of chestnut and pine, lie on their flanks. Palma contains several mineral springs, but there is great want of fresh water. The only stream which is never dried up is that which issues from the Caldera. In 1677 an eruption, preceded by an earthquake, took place from a volcano at the southern extremity of the island, and much damage

was done by the ejected ashes, stones, and lava. The sugar-cane is grown on an elevated plain called Los Llanos. *Santa Cruz* on the eastern coast is the principal town (population 4400). Ribands and stockings are manufactured there from silk produced on the island. The anchorage is good. The cultivated soil is fertile, but the labouring classes are in a wretched condition, notwithstanding their industrious habits.

Lanzarote. LANZAROTE, the most easterly of the group, has a length of 31 miles and a breadth varying from 5 to 10 miles. It is naked and mountainous, bearing everywhere marks of its volcanic origin. Montaña Blanca, the highest point, attains a height of 2000 feet, and is cultivated to the summit. In 1730 the appearance of half the island was altered by a volcanic outburst. A violent earthquake preceded the catastrophe, by which nine villages were destroyed. In 1825 another volcanic eruption took place accompanied by earthquakes, and two hills were thrown up which still emit smoke. The port of Naos on the south-east of the island affords safe anchorage. It is protected by two forts. A short distance inland is the town of Arrecife (population 2700), where a British vice-consul resides. The climate is hot and dry. There is only a single spring of fresh water on the island, and that is in a position difficult of access. From the total failure of water the inhabitants were once compelled to abandon the island. Grain, wine (which is of superior quality), brandy, barilla, orchil, and raisins made from the muscatel grape are the principal articles of export. Dromedaries are used as beasts of burden. *Teguise* (population 1000), on the north-west coast, is the residence of the local authorities. A strait of about 6 miles in width separates Lanzarote from Fuerteventura.

Graciosa. GRACIOSA, a small uninhabited island, is divided from the north-eastern extremity of Lanzarote by a channel a mile in width, which affords the most capacious and only safe harbour for large ships at the Canaries; but basaltic cliffs, 1500 feet high, prevent intercourse with the inhabited part of Lanzarote. A few persons reside on the little island Allegranza, a mass of lava and cinders ejected at various times from a now extinct volcano, the crater of which has still a well-defined edge.

Fuerteventura. FUERTEVENTURA lies between Lanzarote and Grand Canary. It has a length of 52 miles, and an average width of 12 miles. Though less mountainous than the other islands, its aspect is barren. The springs of fresh water are only two, and they are confined to one valley. Lava streams and other signs of volcanic action abound, but there has been no igneous activity since the Spaniards took possession. At each of its extremities are high mountains, which send off branches along the coast so as to enclose a large arid plain. The highest peak reaches 2500 feet. In external appearance, climate, and productions this island greatly resembles Lanzarote. An interval of three years without rain has been known. The wine is bad. Barilla and orchil are largely exported. *Oliva*, with 970 inhabitants, is the largest town. A smaller place in the centre of the island named *Betancuria* is the residence of the authorities. *Cabras*, on the eastern coast (population 1000), is the chief port. Dromedaries are bred here.

Gomera lies 20 miles south-west of Teneriffe. Its greatest length is about 23 miles. The coast is precipitous and the interior mountainous, but it has the most wood and is the best watered of the group. The inhabitants are very poor. The palm trees produce excellent dates; and wine, brandy, orchil, raw silk, and dried fruits are sent to Teneriffe. Dromedaries are bred on Gomera in large numbers. *St Sebastian*, the chief town and a port, has 2240 inhabitants. Columbus resided here before sailing in search of the New World.

HIERRO, or *Ferro*, the most westerly and the smallest island of the group, is somewhat crescent-shaped. Its length is about 18 miles, its greatest breadth about 15 miles, and its circumference probably 50 miles. It lies 92 miles W.S.W. of Teneriffe. Its coast is bound by high steep rocks, which only admit of one harbour, but the interior is tolerably level. Its hill-tops in winter are sometimes wrapped in snow, which, however, does not lie long. Better and more abundant grass grows here than on any of the other islands. The island is exposed to westerly gales, which frequently commit great damage. Fountains of fresh water are few, but there is a sulphurous spring, with a temperature of 102° Fahr. The once celebrated and almost sacred Til tree, which was reputed to be always distilling water in great abundance from its leaves, no longer exists. Only a small part of the cultivable land is under tillage, the inhabitants being principally employed in pasturage. Wine, brandy, orchil, excellent dried figs, and sheep are sent to Teneriffe. At *Valverde*, the principal town, with 4640 inhabitants, the local authorities reside. Geographers were formerly in the habit of measuring all longitudes from Ferro, the most westerly land known to them. The longitude assigned at first has, however, turned out to be erroneous; and the so-called "Longitude of Ferro" does not coincide with the actual longitude of the island.

CANCALE, a seaport town of France, in the department of Ille-et-Vilaine, 10 miles E. of St Malo, on the bay of St Michael. A considerable trade is carried on in oysters, which are found in the bay in great numbers and of excellent quality. In 1758 the duke of Marlborough disembarked an army of 14,000 English here for the purpose of attacking St Malo, but retired without accomplishing anything. Population in 1872, 3814.

CANCAO, CANCAR, or KANG-KAO, otherwise known as Ponthiamus or Potai-mat, or in Chinese, Ha Thian, the capital of a small state in Western Cambodia, on the eastern side of the Gulf of Siam, at the mouth of the River Cancao or Klong Chanda; in 10° 14′ N. lat. and 104° 55′ E. long. The town was once a great centre of Cambodian trade, its port having been declared free by a man of Chinese origin, who took advantage of the civil troubles of Siam to effect his purpose. In 1717, however, the Siamese expelled the merchants who had flocked to the place; and though a considerable exportation of rice and salt is still maintained, the prosperity of the town has largely diminished. The harbour is shallow, though the river in general has a great depth of water. A canal gives communication with the Mekong River.

CANCER, or CARCINOMA (from *cancer*, or *καρκινος*, an eatihg ulcer), is the name given to a class of morbid growths or tumours which occur in man, and also in certain of the lower animals. The term is apt to be somewhat loosely employed, partly owing to the fact that there are not a few forms of diseased growth respecting which it is still a matter of debate whether they are to be regarded as cancerous or not; and in some measure also to the difficulty often experienced in recognizing true cancer particularly in its earlier stages.

The disease exists in various forms, which, although differing from each other in many points, have yet certain common characters to which they owe their special significance.

1. In structure such growths are composed of nucleated cells and free nuclei together with a milky fluid called

cancer juice, all contained within a more or less dense fibrous stroma or framework.

2. They have no well-defined limits, and they involve all textures in their vicinity, while they also tend to spread by the lymphatics and veins, and to cause similar growths in distant parts or organs called "secondary cancerous growths."

3. They are undergoing constant increase, and their progress is usually rapid.

4. Pain is a frequent symptom. When present it is generally of a severe and agonizing character, and together with the local effects of the disease and the resulting condition of ill health or "cachexia," hastens the fatal termination to which all cancerous growths tend.

5. When such growths are removed by the surgeon they are apt to return either at the same or at some other part.

The chief varieties of cancer are *Scirrhus* or hard cancer, *Encephaloid* or soft cancer, and *Epithelial cancer*.

Scirrhus is remarkable for its hardness, which is due to the large amount of its fibrous, and relatively small proportion of its cell elements. It is of comparatively slow growth, but it tends to spread and to ulcerate. Its most common seat by far is the female breast, though it sometimes affects internal organs.

Encephaloid is in structure the reverse of the last, its softness depending on the preponderance of its cell over its fibrous elements. Its appearance and consistence resemble brain substance (hence its name), and it is of such rapid growth as to have given rise to its being occasionally termed *acute cancer*. Its most frequent seats are internal organs or the limbs. Ulceration and hæmorrhage are common accompaniments of this form of cancer.

Epithelial cancer is largely composed of cells resembling the natural epithelium of the body. It occurs most frequently in those parts provided with epithelium, such as the skin and mucous membranes, or where those adjoin, as in the lips. This form of cancer does not spread so rapidly nor produce secondary growths in other organs to the same extent as the two other varieties, but it tends equally with them to involve the neighbouring lymphatic glands, and to recur after removal.

Various views are entertained, and much discussion has taken place respecting the causation of cancer, but little has as yet been satisfactorily ascertained on the point. By some the disease is held to be from the first an entirely local affection, due to some alteration in the nutrition of the part, irrespective of any condition of the system generally, but in course of time coming to assume a malignant form, and to infect the system secondarily. Others, on the contrary, maintain that a certain constitutional condition, either as regards the blood or some of the tissues of the body, must exist prior to the development of the disease to which it gives rise. A third view is that the concurrence of a constitutional and a local cause is necessary for the production of cancer. Without entering into an examination of these opinions, it appears evident that a constitutional element cannot be excluded in view of such well-known facts as a hereditary liability to cancer, and also of its occasional appearance in several parts of the body at one time.

The hereditary tendency in some persons to this disease has long been recognized by medical men; but its extent was not accurately ascertained till Sir James Paget affirmed, as the result of his observations, that in one out of every three cases of cancer a family history of the malady could be traced, and further, that even this probably does not represent the whole extent of the hereditary predisposition to cancer.

Cancer is essentially a disease of degeneracy, all statistics going to show its relatively great frequency after middle life; and the mortality, according to Dr Walshe, goes on increasing with each decade until the eightieth year. Cancer may, nevertheless, attack persons of any age, and instances of its occurrence are not unknown even among young children. It affects females to a much larger extent than males,—this, however, being fully explained by the greater liability of the female breast and of the uterus to the disease than any other organs of the body; for, apart from this, cancer is quite as common among men. It occurs equally among all ranks of life.

The commencement of a cancerous growth is frequently attributed to some local injury, as in the case of blows on the breast, or in the well-known instance of cancer of the lip following the irritation produced by smoking a short clay pipe. But it is only as exciting causes that the influence of such injuries can be admitted; and there must still remain, as necessary to account for the disease, some antecedent condition of the system which gives the particular direction to the form of morbid action in the part.

Cancer tends to advance steadily to a fatal termination, but its duration varies in different cases according to the part affected, and according to the variety of the disease. Soft cancer affecting important organs of the body often proves fatal in a few months, while, on the other hand, cases of hard or epithelial cancer may sometimes last for several years; but no precise limit can be assigned for any form of the disease. In some exceptionally rare instances cancerous growth may exist for a great length of time, and undergo a kind of spontaneous cure, or at least prolonged arrestment.

With respect to the treatment of cancer the only hope of success lies in the entire removal of the disease. This can obviously be only accomplished where the growth affects parts which are within reach of the surgeon. When in such cases the tumour is of recent formation, is limited in its extent, does not largely affect the neighbouring lymphatic glands, and has not as yet produced any marked deterioration of the general health, the surgeon is warranted in operating. Although it must be admitted that the results are generally disappointing from the intense tendency of the disease to recur sooner or later, yet the relief to suffering and the prolongation of life obtained are alone sufficient to justify operative interference when otherwise admissible, not to mention the fact that in some rare instances a cure has thus been achieved. Nor is the view of the constitutional and hereditary nature of cancer necessarily inconsistent with the adoption of such remedial measures,—since, from the analogy of other hereditary diseases, it is probable that these influences are more potent at certain times of life, and that by prompt treatment the period of special liability may be tided over, although the inherent tendency cannot be eradicated. When from the extent of the disease or its existence in internal organs no attempt at removal can be made, all that can be hoped for is the relief of suffering, and it is certain that even in such circumstances much may be done by appropriate medical treatment. It is painful to think how many of the unfortunate sufferers from this malady place themselves in the hands of ignorant persons who profess to be able to cure cancers, but whose violent remedies, if they do not actually destroy life, as has often been the case, only aggravate suffering and entail disappointment.

Cancer is known to occur in many of the lower animals, being probably most common among the domestic tribes, but it presents no special peculiarities as a disease beyond those already referred to. ([illegible])

CANCRIN, FRANZ LUDWIG VON ([illegible]), a German mineralogist and metallurgist, was born in [illegible] at Breitenbach. After acting as professor and [illegible] municipal offices in Hesse and at [illegible], he at

tracted the notice of the Empress Catherine of Russia, who made him director of the salt-mines of Staraja-Russa, councillor of the Imperial College, and, three years before his death, councillor of state. He is the author of a large number of works in German on mineralogy and metallurgy, of which the most important, the *Grundzüge der Berg- und Salzwerkskunde*, published at Frankfort in 13 vols., during the years 1773–1791, has been translated into several languages. He died in 1796.

CANDAHAR. See KANDAHAR.

CANDELABRUM, in Classical Antiquities, a stand for a lamp or lamps, usually of such a height as, when placed on the floor, to be serviceable to a person seated or reclining on a couch. The material varied according to the circumstances of the owner; only those of bronze have survived; but they are many. Generally the form consists of a heavy base resting on three spreading claws. From the base rises a tall usually fluted stem, branching out at the top into two or more arms from which the lamps were hung. On candelabra of this simple form the only place available for ornament was the top of the stem, on which a statuette or a group of figures could be placed; and it appears that very many of the small bronze statuettes now existing in museums had originally served this purpose. Or the lower part of the stem, immediately above the base, could be converted into a figure supporting the stem, as may be seen in several very beautiful examples in the British Museum. There was, however, no limit to the extent to which the original form might be departed from, as many of the candelabra from Pompeii show.

CANDESH, or KANDEISH. See KHANDESH.

CANDIA, the modern name of the island of CRETE (*q.v.*)

CANDIA, formerly the capital and still the most populous city of Crete, to which it has given its name (see CRETE), is situated on the northern shore somewhat nearer the eastern than the western end of the island, in 35° 20′ N. lat. and 25° 9′ E. long. It is still surrounded by its extensive Venetian fortifications; but they have fallen into disrepair, and a good part of the town is in a dilapidated condition, mainly from the effects of earthquakes. The principal buildings are the pasha's palace, the mosques, which are fourteen in number, the two Greek churches, the Armenian church, the Capuchin monastery, the bazaars, and the baths. The town is the seat of a Greek archbishop, and one of the churches ranks as a cathedral. The chief trade is in oil and soap, both of which are of excellent quality; 900 tuns of the former were exported in 1873, and of the latter 40,000 cwts. The coasting trade, which is of considerable importance, is mainly carried on in Turkish vessels. The manufacture of leather for home consumption is an extensive industry, and wine of good quality is produced in the neighbourhood. The which had grown almost inaccessible, was deepened apha Pasha between 1820 and 1840. It is formed most part by the ancient moles, and was never deep to admit the larger vessels even of the Venetians, ere accustomed to anchor in the port of the neigh- island of Standia. A short distance from St Gate there is a small village exclusively inhabited s, who number about seventy families. The popu- the town is estimated at from 15,000 to 18,000, ro-thirds being Turks. Candia, or as it is frequently Iegalo Castro (the Great Fortress), occupies the site ancient *Heracleion*, the seaport of *Gnossus*, and is own by that name to the Greek speaking population. ...ns of the mother city are situated at the distance of about two miles and a half to the S.E. at the village of Makri Teikos or Long Wall. Founded by the Saracens in the 9th century, Candia was fortified by the Genoese in the 12th, and was greatly extended and strengthened by the Venetians in the 13th, 14th, and 15th centuries. It was besieged by the Turks under the Vizier Achmet in 1667; and, in spite of a most heroic defence, in which the Venetians lost 30,000 in killed and wounded, it was forced to surrender in 1669. (Spratt's *Travels in Crete*, 1865.)

CANDIAC, JEAN LOUIS PIERRE ELIZABETH DE MONTCALM DE, a child of astonishing precocity, born at the Château de Candiac, in the diocese of Nîmes in France, in 1719. At four years of age he read Latin, either printed or in manuscript; and at six he understood Greek and Hebrew, had an astonishing acquaintance with arithmetic, history, geography, and heraldry, and had read many of the best authors. His extraordinary powers attracted the attention of the learned; and it was for his benefit that the typographic board was contrived by M. Dumas, who superintended his instruction. He died at Paris in 1726.

CANDLE, a cylindrical rod of solid fatty or waxy matters, enclosing a central fibrous wick, and designed for giving light.

The raw materials mostly used for candles are tallow and palm oil; they are also made from wax, cocoa-nut oil, paraffin, spermaceti, the mineral wax called *ozokerit*, &c. For ordinary tallow candles, the mutton or ox tallow, taken as soon as possible after separation from the carcase, is sorted, cut into pieces, and melted in a pan; the membranous matters, which are known as *graves* or *cracklings*, collect at the surface; and the liquid tallow, after being strained through a sieve and washed with boiling water, is ready for use. The candles are made either by dipping or by moulding.

The common tallow candles, however, are greatly inferior, both as regards illuminating power and absolute expense, to those now obtained from raw fats by processes based on the researches of some French chemists. The stearine or stearic acid industry, which is now of large proportions, originated in M. Chevreul's discovery that fats are composed of one or more inflammable fatty acids combined with a comparatively uninflammable base, glycerine. Thus, tallow or palm oil consists of palmitic, stearic, and oleic acids, with glycerine. An economical method of separating the acids and the glycerine was first discovered in 1831 by De Milly, who used lime for the purpose, in place of potash and soda, the substances adopted by Chevreul and Gay-Lussac in their patent of 1825. The factory established by De Milly and Motard near the *Barrière de l'Étoile*, in Paris, gave the "star candles" their name.

In this saponification by means of lime, the melted fat is stirred some hours with a mixture of lime (about 14 per cent. of the weight of the fat) and water. The lime combines with the acids to form a soap, and the glycerine, dissolved in the water, is then run off. Next, the lime soap is decomposed, under heat, by means of sulphuric acid, which unites with the lime, the fatty acids being set free. 100 parts of the fatty acids, at this stage, give on an average 45·9 parts of a mixture of stearic and palmitic acids. The acids are washed with water, and allowed to cool and solidify. They are then pressed in press bags, both in the cold state and with application of heat, to expel oleic acid, which is liquid. After further purification, they are ready to be made into "stearine candles."

Various other methods of saponification have come into practice. Thus it was found that the amount of lime in the foregoing process might be greatly reduced if the mixture were heated to a higher temperature with superheated steam. In another method, sulphuric acid is added to the fat, and the mixture is heated. The black mass produced is washed with boiling water till all the fatty acids are completely freed from sulphuric acid. Then they are distilled with the aid of superheated

steam, cooled and pressed. This process offers advantages in treatment of impure and refuse fats, but it involves some waste of fat. Distillation has been dispensed with in the simpler process of De Milly (who found that fat could be saponified with sulphuric acid without formation of tarry matter), and more recently in that of Bock. According to the latter, most neutral fats consist of small fat spherules, with thin albuminous skins. A little strong sulphuric acid introduced, under given conditions, has the effect of partly carbonizing the skins and liberating the neutral fat, which is then ready for decomposition by boiling with water in open vessels. The fatty acids obtained after decomposition (they are about 94 per cent. of the original fat) are of a dark colour, from the presence of portions of the carbonized skins. By suitable oxidation with acid, the colouring matters are rendered precipitable. The fatty acids are afterwards pressed. A method of saponification specially suitable for palm oil is that of heating the substance in a still to a temperature of 290° to 315° C., and passing a current of superheated steam through it. Saponification by water under high pressure seems to have been first observed by Faraday in 1823; and the process has been developed industrially by Tilghmann, Melsens, and others.

The wicks of candles are generally of cotton-yarn, and, to secure good steady combustion, they should be of uniform thickness, and free from knots or loose threads. The parallel threads of the wick are commonly twisted into a loose spiral. Plaited wicks were introduced by Cambacérès, his object being to do away with the necessity of snuffing. Through twisting of the plaited wick as it burns, the protruding end is kept just outside the flame, and consumed to ash by the surrounding air. In stearine candles, the combustibility is often aided by impregnating the wicks with a solution of boracic acid; a glass bead is formed at the top of the burning wick through the action of the acid on the constituents of the ash, and this by its weight turns the wick out of the flame. Another form of wick for stearine candles is prepared by first winding cotton-yarn round a wire. The covered rod is inserted in the mould, and after moulding is withdrawn from its covering, which remains as the wick. Machinery is now used in making various kinds of wick.

In the production of candles by dipping, the wicks are first arranged in pendant position on sticks on a frame corresponding in size to the dipping-trough, and each frame is suspended from one of a number of cross arms projecting from and jointed with an upright beam which turns on pivots. The workman turns these arms round, and as each frame comes over the dipping-trough, he presses the frame down, so that all the wicks are immersed in the tallow. This coats the wicks with one thin layer; the arms are then turned round, and each frame, as it successively arrives over the cistern, is treated the same way. The layer of tallow added in the dipping becomes consolidated before the turn comes for that set of candles to receive a second dip; and the arms are turned round and the candles dipped again and again, until all have acquired the requisite thickness and weight, which is known by a counterpoise fixed to the arm.

In the process of moulding, on the other hand, a number of slightly conical pewter moulds (ten to eighteen), finely-polished inside, are fixed by the larger extremity to a kind of trough, their taper ends projecting downwards. The wick is then fixed in the centre of the mould by being drawn through an aperture at the point of the mould which forms the upper end of the candle, and is retained in its place at the open extremity within the trough by means of a wire or other arrangement. The liquid material, being poured into the trough, fills all the moulds, and as soon as it is solidified, any redundance is removed and the candle drawn out of the mould by the end of the wick which has been held by the wire. *Moulding-machines* are in common use, in which as one set of candles is discharged from the moulds, the latter are, by the same movement, rewicked for the next process of filling. A reel of wick is connected with each mould. The discharged candles are held in a horizontal position, while a knife severs the wicks. Before receiving the fat, the moulds are slid on a railway into a hot closet to be heated. Each machine holds about 200 frames of moulds, and each frame contains 18 bobbins, each of which at first has 60 yards of cotton wick.

The *stearine* candles are made by moulding. A difficulty arose from the tendency of stearic acid to crystallize in large foliated crystals, the candles produced being thus irregular in structure and brittle. The remedy at first adopted was the addition of a little arsenious acid, but this proved detrimental to health. The method now employed is to mix 2 to 6 per cent. of white wax with the stearic acid when molten, or to add about 20 per cent. of paraffin.

Wax is a material not very suitable for moulding on account of its contraction in cooling and adhesion to the moulds. Several varieties of wax, besides that of bees, are used in candle-making. The wax is first submitted to a bleaching process; and the candles are generally made by ladling molten wax upon the wicks from a large basin over which they are suspended from an iron ring. When the proper thickness has been acquired, the candles are taken down and rolled on a marble slab, or wooden table, and are then cut and trimmed. Where wax candles are made by the hand, the wax, being kept soft in hot water, is applied bit by bit to the suspended wick. Presses have been contrived for making wax candles; they are of similar arrangement to those for making continuous lengths of lead and block-tin pipes. The wick is so directed that it is concentrically surrounded with soft wax when ejected from the spout of the cylinder of the press, thus forming a continuous candle, which is afterwards cut up into lengths. Wax tapers of various thickness are produced by drawing the uncut wick through molten wax in a pan, then through a draw iron provided with somewhat conical apertures, arranged like those for wire-drawing, in the side of the vessel. The waxed wick is wound very slowly on a drum, the wax having time to solidify in its passage. The process may be repeated several times with drawing irons of increasing aperture.

Paraffin, now largely made into candles, is obtained from native petroleum (Rangoon oil), or from the products of dry distillation of peat, brown coal, Boghead mineral, lignite, bituminous schist, or ozokerit. The paraffin of candles is generally a mixture of several paraffins having different melting points. A little stearic acid (5 to 15 per cent.) is usually added, in order to make the candles more rigid, and in some instances to raise the temperature of fusion: it also facilitates colouring. The candles are moulded much in the same way as stearine candles. The molten paraffin, however, is solidified suddenly by immersion of the warm moulds in cold water, the paraffin being thus prevented from becoming crystalline and opaque. For black paraffin candles the paraffin is heated with anacardium shells, the resin of which is dissolved by it.

The mineral wax or paraffin known as *ozokerit* is found in the Carpathian Mountains, Galicia, Bohemia, and elsewhere. At the low temperature of 66° C. it becomes fluid, and other less fusible substances can then be added. Dr Letheby has observed that the light of 754 [illegible] candles equals that of 891 paraffin, or 1150 wax candles. *Spermaceti* is the solid matter obtained from the oil of the sperm whale by filtration. In further preparation for candles it is hardened and whitened by pressure, and refined by a weak

alkaline ley. A little wax or paraffin is added to prevent crystallization. Sperm candles have a high illuminating power, and notwithstanding their costliness, a considerable trade is done in them. The well-known *composite* candles are made of a mixture of palm-acid and the stearine of cocoa-nut oil in various proportions. *Belmont sperm* is made of hot-pressed distilled palm-acid; *Belmont wax* of the same mineral tinged with gamboge. *Night lights* are short thick cylinders of fat, with a very thin wick, calculated usually to burn from six to ten hours. In making them, the melted fat is poured into shallow moulds having movable bottoms, with a projecting wire which moulds a narrow tube for the wick. By pressing up the bottom the cylinders of fat are ejected; a wax-covered wick supported on a small piece of tin is afterwards inserted, and is cemented at the bottom part by pressing the night light on a warm porcelain slab. *Child's night lights* are made in paper cases of the nature of pill boxes, having a hole in the bottom through which the tin-supported and waxed wick has been inserted.

A candle is a simple but ingenious contrivance for supplying a flame with as much melted material as it can consume without smoking. If the thickness of the candle be properly adapted to that of the wick, the fatty matter immediately below the flame is melted, so that a cup-like reservoir is produced, always properly filled for feeding the flame. The fibres of the wick act as a congeries of capillary tubes which convey the fluid fat into the flame, where, being exposed to a high temperature and sheltered from the air by the outer shell of flame, it becomes subjected to a dry distillation. The inflammable vapour thus produced rises, and by constant combustion diminishes in quantity and consequently in diameter, until at length it entirely disappears in a point. A current of air from below is produced by the heat of the flame; the oxygen of the air, aided by the high temperature, decomposes the inflammable vapour of the fat into hydrogen and carbon, and unites with these to form water and carbonic acid.

The interior dark part of a candle or other flame contains unignited inflammable vapour which will not of itself support combustion; it may be drawn off with a glass tube and ignited at a distance. According to Frankland, the luminosity of an ordinary candle, lamp, or gas flame is due, not, as commonly supposed, to the separation of solid particles of carbon, but to that of very dense hydrocarbons, which produce the same effect as the vapours of arsenic and phosphorus in their respective flames.

The excise duty of ½d. per lb. on tallow candles, and 3½d. per lb. on wax and spermaceti candles, was repealed in 1832. (A. B. M.)

CANDLEMAS, a church festival, held on the 2d of February, which has in Scotland been chosen as one of the four term-days. The festival commemorates the purification of the Virgin; and the observances to which it owes its name, viz., the lighting of candles, and, in the Roman Catholic Church, the consecration of the candles which are to be used during the year for ecclesiastical purposes, are said to have an emblematical reference to the prophecy of Simeon that the child Jesus should become "a light to lighten the Gentiles." The institution of this feast dates probably from the reign of Justinian, and the year 542 is sometimes fixed upon as that of its first celebration. It is supposed to have grown out of the heathen festivals held in this month,—a view which is supported by the following considerations:—(1), The word February (connected with *februare*) denotes purification; (2), in this month the purification of the people took place; (3), the rites of the Lupercalia, which were celebrated on the 15th, included the lighting of candles, in allusion to those used by Ceres in her search for Proserpine; and (4), the origin of other Christian feasts appears to have been similar.

CANDLESTICK, in the earlier meaning of the word, was the name applied to any form of support on which lights, whether candles or lamps, were fixed; and so it happens that what would now be called a candelabrum is still sometimes spoken of from tradition as a candlestick, *e.g.*, as when Moses was commanded to make a candlestick for the tabernacle, of hammered gold, a talent in weight, and consisting of a base with a shaft rising out of it and six arms, and with seven lamps supported on the summits of the six arms and central shaft. When Solomon built the temple, he placed in it ten golden candlesticks, five on the north and five on the south side of the Holy Place; but after the Babylonish captivity, the golden candlestick was again placed in the temple, as it had been before in the tabernacle by Moses. On the destruction of Jerusalem by Titus, it was carried with other spoils to Rome. Representations of the seven-branched candlestick, as it is called, occur on the arch of Titus at Rome, and on antiquities found in the Catacombs at Rome. The primitive form of candlestick was a torch made of slips of bark, vine tendrils, or wood, dipped in wax or tallow, tied together and held in the hand by the lower end, such as are frequently figured on ancient painted vases. The next step was to attach to them a cup (*discus*) to catch the dripping wax or tallow. See CANDELABRUM.

CANDLISH, ROBERT SMITH, D.D. (1806–1873), an eminent Scottish clergyman, was born at Edinburgh on the 23d March 1806. His father, who was a teacher of medicine, having died a few weeks after his birth, the widow and family removed to Glasgow, where young Candlish was brought up and educated. In 1818 he entered the University of Glasgow, and after a curriculum of five sessions, during which he carried off many honours, he duly graduated M.A. Entering immediately on his professional studies, he passed during the years 1823–26 through the prescribed course at the divinity hall, then presided over by Dr Stevenson MacGill. While carrying on his studies he had been largely occupied, according to the common Scotch practice, with private teaching, and on leaving the divinity hall he accompanied a pupil as private tutor to Eton. On the termination of this engagement in 1829, he entered upon his own proper work, having been licensed to preach during the summer vacation of the previous year. He was employed for two years as assistant to the minister of the parish of St Andrews, Glasgow, and he subsequently occupied a similar situation for about the same period in the parish of Bonhill, Dumbartonshire. In each case the entire duties of the charge devolved upon him, and he fulfilled them with characteristic energy and zeal. It was not until 1834, after he had offered himself for service in Canada, in the belief that he was not to find a sphere of labour at home, that he obtained a settled charge as minister of the important parish of St George's, Edinburgh. Here he at once took the place he so long held as one of the ablest preachers in Scotland. Destitute of natural oratorical gifts, and somewhat ungainly in his manner, he attracted and even rivetted the attention of his audience by a rare combination of intellectual keenness, emotional fervour, spiritual insight, and power of dramatic representation of character and life. His theology was that of the Scottish Calvinistic school, but he combined with the narrowness that springs from strong conviction the breadth that springs from tender sympathy. With such qualities it was natural that he should gather round him one of the largest and most intelligent congregations in the Scottish metropolis.

From the very commencement of his ministry in Edinburgh, Candlish took the deepest interest in ecclesias-

tical questions, and he soon became involved as one of the chief actors in the struggle which was then agitating the church. His first Assembly speech, delivered in 1839, placed him at once among the leaders of the party that afterwards formed the Free Church, and his influence in bringing about what is known as the Disruption was inferior only to that of Chalmers. As a debater he had powers of the highest order, which would have won for him a foremost place in any deliberative assembly. Great as was his popularity as a preacher, it was in the ecclesiastical arena that his ability chiefly showed itself, and probably no other single man had from first to last so large a share in shaping the constitution and guiding the policy of the Free Church. He was actively engaged at one time or other in nearly all the various schemes of the church, but special mention should be made of his services in the Education Committee, of which he was convener from 1846 to 1863, and in the unsuccessful negotiations for union among the non-established Presbyterian denominations of Scotland, which were carried on during the years 1863–73. In the Assembly of 1861 he filled the moderator's chair.

As a theologian the position of Candlish was perhaps inferior to that which he held as a preacher and ecclesiastic, but it was not inconsiderable. So early as 1841 his reputation in this department was sufficient to secure for him the nomination to the newly-founded chair of Biblical Criticism in the University of Edinburgh. The appointment was, however, not ratified by the Home Secretary in consequence of a representation made in the House of Lords, by the earl of Aberdeen, that Candlish had set himself in opposition to the law of the land by preaching in the parish of Huntly in spite of an interdict from the Court of Session. By a somewhat curious coincidence a second appointment to a professorship was also nullified, though in this case by his own act, and after a few months' tenure of the office. In 1847 Candlish, who had received the degree of D.D. from Princeton, New Jersey, in 1841, was chosen by the Assembly of the Free Church to succeed Chalmers in the chair of divinity in the New College, Edinburgh. After partially fulfilling the duties of the office for one session, he was led to resume the charge of St George's, the clergyman who had been chosen by the congregation as his successor having died before entering on his work. In 1862 he was again connected with the New College, being appointed principal in succession to Cunningham, with the understanding that he should still retain his position as minister of St George's. Some months before this he had obtained the assistance of a colleague in his pastoral work, but he continued to preach, with one or two intervals of somewhat protracted illness, until within a short time of his death, which occurred on the 19th October 1873.

Though his greatest power was not displayed through the press, Candlish made a number of somewhat important contributions to theological literature. In 1842 he published the first volume of his *Contributions towards the Exposition of the Book of Genesis*, a work which was completed in three volumes several years later. In 1854 he delivered, in Exeter Hall, London, a lecture on the *Theological Essays* of the Rev. F. D. Maurice, which he afterwards published, along with a fuller examination of the doctrine of the essays. A treatise entitled *The Atonement; its Reality, Completeness, and Extent* (1861) was based upon a smaller work which first appeared in 1845. In 1864 he delivered the first series of Cunningham lectures, taking for his subject *The Fatherhood of God*. Published immediately afterwards, the lectures excited considerable discussion on account of the peculiar views they represented. Further illustrations of these views were given in two works published about the same time as the lectures, one a treatise *On the Sonship and Brotherhood of Believers*, and the other an exposition of the first epistle of St John. Among his other works were *Life in a Risen Saviour*; *Scripture Characters*; *Reason and Revelation*; and *The Christian's Sacrifice and Service of Praise*. A posthumous volume of sermons with a short prefatory biographical sketch appeared in 1874.

CANDOLLE, AUGUSTIN PYRAME DE. See DE CANDOLLE.

CANE, a name applied to many plants which are possessed of long, slender, reed-like stalks or stems, as, for example, the sugar-cane, the bamboo-cane, or the reed cane. From the use as walking-sticks to which many of these plants have been applied, the name cane is improperly given to sticks irrespective of the source from which they are derived. Properly it should be restricted to a peculiar class of palms, known as ratans, included under the two closely allied genera *Calamus* and *Dæmonorops*, of which there are a large number of species. The plants are found widely extended throughout the islands of the Indian Archipelago, the Malay Peninsula, China, India, and Ceylon; and examples have also been found in Australia and Africa. They were described by the learned Rumphius, under the name of Palmijunci, as inhabitants of dense forests into which the rays of the sun scarce can penetrate, where they form spiny bushes, obstructing the passage through the jungle. They rise to the top of the highest trees and fall again so as to resemble a great length of cable, adorned, however, with the most beautiful leaves, pinnated or terminating in graceful tendrils. The plants creep or trail along to an enormous length, sometimes, it is said, reaching 500 feet. In the Paris exhibition of 1855 two examples of *Calamus verus*, measuring respectively 270 and 230 feet, were exhibited. The stem in few cases exceeds 1 inch in diameter, and it is mostly of much smaller dimensions. When growing it is sheathed in a base of numerous leaves, which the natives, in preparing the canes for the market, strip off by pulling the cut plant through a notch made in a tree. The canes always present distinct rings at the junction of the sheathing leaves with the stem. They assume a yellow colour as they dry; and those imported from Calcutta have a glossy surface, while the produce of the Eastern Archipelago presents a dull exterior.

Canes, on account of their lightness, length, strength, and flexibility, are used for a great variety of purposes by the inhabitants of the countries in which they grow. Split into thin strips they are twisted to form ropes and ships' cables, an application mentioned by Captain Dampier in his *Voyages*. A more important application, however, is for basket-work, and for making chairs, couches, pillows, &c., as the great strength and durability of thin and easily-prepared strips admit of such articles being made of

them efficient substitutes for whalebone. The walking-stick "canes" of commerce include a great many varieties, some of which, however, are not the produce of trailing palms. The well-known Malacca canes are obtained from *Calamus Scipionum*, the stems of which are much stouter than is the case with the average species of *Calamus*.

CANEA, or KHANIA, the principal seaport and since 1841 the capital of Crete, is finely situated on the northern coast of the island, about 25 miles from its western extremity, on the isthmus of the Akrotiri peninsula, which lies between the Bay of Canea and the Bay of Suda. Its latitude is 35° 31′ N., and its longitude 24° 1′ E. Surrounded by a massive Venetian wall, it forms a closely-built, irregular, and overcrowded town, though of late years a few of its streets have been widened. The ordinary houses are of wood; but the more important buildings are of more solid materials. The Turks have a number of mosques; there are Greek churches and a Jewish synagogue; an old Venetian structure serves as a military hospital; and the prison is of substantial construction. The town is the seat of a Greek bishop, who is suffragan to the metropolitan at Candia; and it is the official residence of the European consuls. The harbour, formed by an ancient transverse mole nearly 1200 feet long, and protected by a lighthouse and a fort, would admit vessels of considerable tonnage; but it has been allowed to silt up until it shoals off from 24 feet to 10 or even 8, so that large vessels have to anchor about four or five miles out. The principal articles of trade are oil and soap, of which there were exported, in 1874, 530 tuns and 50,000 cwts. respectively. A few small ships are built in the port, and there is a pretty extensive manufacture of leather. The fosse is laid out in vegetable gardens; public gardens have been constructed outside the walls; and artesian wells have been bored by the Government. To the east of the town a large Arab village has grown up, inhabited for the most part by natives of Egypt and Cyrenaica, who act as boatmen, porters, and servants, and number from 2000 to 3000; while about a mile off on the rising ground is the village of Khalepa, where the consuls and merchants reside. The population of the town is estimated at 12,000. Canea probably occupies the site of the ancient Cydonia, a city of very early foundation and no small importance. During the Venetian rule it was one of the strongest cities in the island, but it fell into the hands of the Turks in 1646, several years before the capture of Candia. In 1856 it suffered from an earthquake. The neighbouring plain is famous for its fruitfulness, and the quince is said to derive its name *Cydonia* from the town.

CANEPHORI was the title given to the girls who at Athens were annually selected from noble families to walk in the procession at the Panathenaic and apparently also at other festivals, carrying on their heads baskets containing the implements and apparatus necessary for a sacrifice. The gracefulness of the attitude which may be seen in the figures of Canephori on the frieze of the Parthenon in the British Museum, is known to have suggested itself as a subject for sculpture to Polycletus and Scopas. This type of statue also came to be used in architecture to support light entablatures, in which case they are sometimes identified with Caryatides.

CANGA-ARGUELLES, JOSÉ, Spanish statesman, was born in 1770, and died in 1843. He took an active part in the Spanish resistance to Napoleon, in a civil capacity, and was an energetic member of the Cortes of 1812. On the return of the Bourbon line in 1814, Canga-Arguelles was sent into exile in the province of Valencia. On the restoration in 1820 of the constitution of 1812, he was appointed minister of finance. He continued at this post till the spring of 1821, distinguishing himself by the zeal and ability with which he sought to reform the finances of Spain. It was high time; for the annual deficit was greater than the entire revenue itself, and landed and other property was, to an unheard-of extent, monopolized by the priests. The measures he proposed had been only partially enforced, when the action of the king with regard to the ministry, of which he was a member, obliged him to resign. Thereafter, as a member of the Moderate Liberal party, Canga-Arguelles advocated constitutional government and financial reform, till the overthrow of the constitution in 1823, when he fled to England. He did not return to Spain till 1829, and did not again appear in public life, being appointed keeper of the archives at Simancas. He is the author of three works:—*Elementos de la Ciencia de Hacienda* (Elements of the Science of Finance), London, 1825; *Diccionario de Hacienda* (Dictionary of Finance), London, 1827; and *Observaciones sobre la guerra de la Peninsula* (Observations on the Peninsular War), in which he endeavoured to show that his countrymen had taken a far more effective part in the national struggle against the French than English historians were willing to admit.

CANGIAGI, or CAMBIASO, LUIGI (1527–1585), a distinguished painter, was born at Genoa in 1527, and died at the Escorial in 1585. He received his first lessons in the art of painting from his father, and completed his education at Rome, where he studied with particular care the masterpieces of Michelangelo. At a very early age he had gained a high reputation as an artist, and in 1583 he was invited to Spain by Philip II., who desired his assistance in the decoration of the Escorial. He painted the ceiling of the choir, representing the Assemblage of the Blessed. It is considered his best work. Among his other productions which were highly esteemed were the Rape of the Sabine Women, the Sleeping Cupid, and Judith. Most of his paintings are in Genoa and Spain; the Sleeping Cupid is in the royal collection at Paris.

CANICATTI, a town of Sicily, in the province of Girgenti, which dates, it is believed, from the Saracenic occupation. It is well built and finely situated on the slope of a hill. The vine, orange, olive, and almond grow abundantly in the neighbourhood, and the inhabitants devote themselves chiefly to agricultural pursuits. Population, 20,908.

CANINA, LUIGI (1793–1856), an Italian archæologist and architect, was born at Casale in Piedmont. He became professor of architecture at Turin, and his most important works were the excavation of Tusculum in 1829, and of the Appian Way in 1848. He is the author of a great number of works on archæology and architecture, of which several were published in a most magnificent and costly form by his patroness, the queen of Sardinia. Of these may be mentioned *L'Architettura Romana*, 1830; *L'Architettura Greca*, 1833; *Descrizione storica del foro Romano e sue adjacenze*, 1834; *Descrizione dell' antico Tusculo*, 1841; *Sull' Architettura più propria dei tempi cristiani*, 1843.

CANINI, GIOVANNI AGNOLO (1617–1666), a designer and engraver, born at Rome in 1617. He was a pupil of Domenichino, and afterwards of Barbalunga. He painted some altarpieces at Rome, including two admired pictures for the church of San Martino a' Monti, representing the Martyrdom of St Stephen and of St Bartholomew. His painting aimed at general effect, not at precision of detail. Having accompanied Cardinal Chigi to France, he was encouraged by the minister Colbert to carry into execution his project of designing, from medals, antique gems, and similar sources, a series of portraits of the most illustrious characters of antiquity, accompanied with memoirs; but shortly after the commencement of the undertaking Canini died at Rome, in 1666. The work, however, was prosecuted by his brother Marcantonio, who, with the assistance of Picard and Valet, completed and published it in

1699, under the title of *Iconografia di Gio. Ag. Canini*. It contains 150 engravings. A reprint in Italian and French appeared at Amsterdam in 1731.

CANITZ, FRIEDRICH RODOLPH LUDWIG, BARON VON (1654–1699), a German poet and politician of noble family, was born at Berlin in 1654. He attended the universities of Leyden and Leipsic, and travelled in England, France, and Italy. In 1680 he became councillor of legation, and Frederick I. made him councillor of state, privy councillor, baron of the empire, and plenipotentiary at the Hague, all which positions he appears to have filled with credit. His reputation is, however, founded upon his verse. He believed that a great reform might be effected in German literature by the introduction of the rules of French taste; and, consequently, he became an imitator of Boileau, and through him of Horace,—the polished grace of whose verse he attained in some measure, though he does not always avoid turgidity and bombast.

CANNÆ, in Ancient Geography, a town of Apulia, on the River Aufidus, 6 miles from its mouth. It is famous for a terrible defeat which the Romans received there from the Carthaginians under Hannibal, 216 B.C. A great diversity of opinion has prevailed as to the exact spot on which the battle was fought, whether, as has been the general belief, on the south side of the river, or on the north bank, as is maintained by the best authorities, including Niebuhr, Swinburne, &c. The site of the town, which continued to exist at least till the 13th century, is still marked by ancient ruins, among which the most important are those of an aqueduct, an amphitheatre, and a triumphal arch. In a neighbouring rock are several large sepulchral excavations, in which vases and paintings have been discovered.

CANNES, a seaport of France, in the department of Alpes-Maritimes, on the Mediterranean, 15 miles S.W. of Nice and 25 miles N.E. of Draguignan, in 43° 34′ N. lat. and 7° 0′ E. long. It enjoys a southern exposure on a seaward slope, and is defended from the northern winds by ranges of hills. Previous to 1831, when it first attracted the attention of Lord Brougham, it mainly consisted of the old quarter (named Sucquet), and had little to show except an ancient castle, and a church on the top of Mont Chevalier, dedicated in 1603 to Nôtre Dame d'Espérance; but since that period it has become a large and important town, and one of the most fashionable winter resorts in the south of France, much frequented by English visitors. The neighbourhood is thickly studded with villas, which are solidly built of a stone so soft that it is sawn and not hewn. There is an excellent quay, and a beautiful promenade runs along the beach; and numerous sheltered roads stretch up the valleys amidst groves of olive trees. On the top of the hill behind the town are a Roman Catholic and a Protestant cemetery. In the most prominent part of the latter is the grave of Lord Brougham, distinguished by a massive stone cross standing on a double basement, with the simple inscription—"Henricus Brougham, Natus MDCCLXXVIII., Decessit MDCCCLXVIII.;" and in the immediate vicinity lies James, fourth duke of Montrose, who died December 1874. The country around is very beautiful and highly fertile; orange and lemon trees are cultivated like peach-trees in England, while olives, almonds, figs, peaches, grapes, and other fruits are grown in abundance, and, along with the produce of the fisheries, form the chief exports of the town. Essences of various kinds are manufactured, and flowers are extensively cultivated for the perfumers. The climate of Cannes has been the subject of a considerable variety of opinion,—the preponderance being, however, in its favour. According to Dr De Valcourt, it is remarkable by reason of the elevation and regularity of the temperature during the height of the day, the clearness of the atmosphere and abundance of light, the rarity of rain and the absence of fogs. The following are a few of his numerous observations of winter temperature, given in degrees Fahr.:—

	1865-1867.		1872-1873.	
	Maxima.	Minima.	Maxima.	Minima.
November.	72 to 56	56 to 34	67 to 47	59 to 34
December.	69 ,, 52	56 ,, 34	60 ,, 47	44 ,, 25
January.	65 ,, 47	50 ,, 27	62 ,, 50	50 ,, 34
February.	65 ,, 56	53 ,, 38	69 ,, 52	50 ,, 39
March.	71 ,, 49	54 ,, 38	69 ,, 56	54 ,, 39
April.	76 ,, 68	58 ,, 39	75 ,, 57	58 ,, 35

Cannes is a place of great antiquity, but its earlier history is very obscure. It was twice destroyed by the Saracens in the 8th and the 10th centuries; but it was afterwards repeopled by a colony from Genoa. In 1815 Napoleon landed in the vicinity after his escape from Elba; and opposite the town is the island of St Marguerite (one of the Lerins), in the citadel of which the Man with the Iron Mask was confined from 1686 to 1698, and which has acquired a recent notoriety as the prison whence Marshal Bazaine escaped in August 1874. Population of the town in 1872, 9618.

See De Valcourt's *Cannes and its Climate*, London, 1873, and *Climatologie des Stations Hivernales du Midi de la France*, Paris, 1865.

CANNIBALISM, the eating of human flesh by men. This practice has existed from the most ancient times, and has given rise to descriptive terms such as Gr. ἀνθρωποφάγος (Lat. *anthropophagus*), Anglo-Sax. *man-æta*, Eng. *man-eater*. Since the discovery of the New World, the name of the *Caribs* of the West India Islands, recorded by Columbus under the Latinized forms *Canibales* or *Caribales*, has come into popular use as a generic term for man-eaters, *cannibals*.

*Man being by nature carnivorous as well as frugivor*ous, and human flesh being not unfit for human food, the question first arises why mankind generally have not only avoided it, but have looked with horror on exceptional individuals and races addicted to cannibalism. It is evident on consideration that both emotional and religious motives must have contributed to bring about this prevailing state of mind. Simple association of thoughts causes the remains of a dead kinsman or friend to be treated with respect and tenderness, as may be seen from the conduct of some of the rudest races. Acting in another way, the same ideal association attaches the horror of death to anything connected with the dead, so that many tribes will avoid the mention of a dead man's name, and will even abandon his hut, and destroy the furniture he has used; this sentiment must tend to preserve the corpse from violation. Moreover, the religious doctrine that the soul outlives the body,

for storing as well as from their reckless improvidence, should in severe climates be often driven to this extremity. For example, it is known that the miserable natives of Tierra del Fuego, when starving in winter, would throttle and devour the oldest woman of the party; when asked why they did not rather kill their dogs, they replied, "Dog catch otters!" (Fitzroy, *Voy. of Adventure and Beagle*, vol. ii. p. 183). For accounts of cannibalism and murder under stress of hunger in Australia see Salvado, *Memorie dell' Australia*, p. 240; Waitz, *Anthropologie der Naturvölker*, vol. vi. p. 749; among American tribes, Bancroft, *Native Races of Pacific States*, vol. i. p. 120; Back, *Exp. to Great Fish River*, p. 227; Waitz, vol. iii. p. 89; in Polynesia, Ellis, *Polynesian Researches*, vol. i. p. 359; Martin, *Mariner's Tonga Islands*, vol. i. p. 116.

II. *Fury* or *Bravado.*—The North American Indian phrases as to eating the flesh and drinking the blood of their enemies are not to be taken as mere metaphor, but as referring to acts really done. There is even an Iroquois legend of a dialogue between the Manitu (Great Spirit) and a warrior who defends the eating of slain enemies as satisfying at once hunger and revenge (Crèvecœur, *Journey in Pennsylvania*; Klemm, *Allgemeine Culturgeschichte*, vol. ii. p. 28). For actual details of this ferocious custom see Schoolcraft, *Indian Tribes*, vol. iii. p. 242; Hennepin, vol. ii. p. 159; J. G. Müller, *Amerikanische Urreligionen*, p. 145; Waitz, vol. iii. p. 159. Among the Polynesians, there is similar evidence of warriors devouring the flesh and drinking the blood of the slain enemy, where the purpose seems clearly that of inspiring terror and gratifying vengeance. (See Ellis, *Polynesian Researches*, vol. i. p. 309; Turner, *Polynesia*, p. 194; Waitz, vol. vi. p. 158.)

III. *Morbid Affection.*—Cases of the dead being devoured by relatives and friends (especially children by parents) from a sentiment of affection are recorded among low savage tribes, see Spix and Martius, *Reise in Brasilien*, vol. ii. p. 692; Angas, *Savage Life in Australia, &c.*, vol. i. p. 73; Howitt, *Impressions of Australia*, p. 134; Gerland, *Aussterben der Naturvölker*, p. 66. Such accounts are not, however, numerous, and sometimes, at least, may properly belong to other classes. The most remarkable is the often-quoted passage of Herodotus (iv. 26), describing the funeral feasts of the Issedones of Central Asia, where the relatives ate the body of the deceased with other meat, the skull being set in gold and preserved; these were sacred rites done in honour of the dead. As lately as the 13th century, William of Ruysbruck was told that the people of Tibet had till recently kept up this custom of eating their deceased parents, and still used their skulls as drinking-cups (Rubruquis in *Pinkerton's Coll. of Voyages*, vol. vii. p. 54).

IV. *Magic.*—Few notions belonging to primitive savage magic are more intelligible or more widely spread than the belief that the qualities of any animal eaten will pass into the eater. This motive naturally leads to cannibalism (see Stanbridge, in *Trans. Ethnological Soc.*, vol. i. p. 289), especially in war, where the conqueror eats part of the slain enemy with the avowed purpose of making himself brave. This idea is found among the natives of Australia (see Macgillivray, *Voyage of Rattlesnake*, vol. i. p. 152, vol. ii. p. 6), and not less distinctly in New Zealand (Ellis, vol. i. p. 358); among the North American Indians, when warriors would devour the flesh of a brave enemy, and particularly the heart as the seat of courage (Keating, *Long's Expedition*, vol. i. p. 102); also in Ashantee (J. L. Wilson, *Western Africa*, p. 168). An English merchant in Shanghai, during the Taeping siege, met his Chinese servant carrying the heart of a rebel, which he was taking home to eat to make him brave (Tylor, *Early History of Mankind*, p. 133). The imagined value of human flesh in giving magical powers to the eater is known to the savage world both in Australia and America (Eyre, *Central Australia*, vol. ii. pp. 255, 329; Angas, vol. i. p. 123; Keating, vol. i. p. 103; Waitz, vol. iii. p. 159, vol. vi. p. 748). This idea even holds a place in the more cultured magical traditions of Asiatic and European nations (see Gerland, p. 66; Schaafhausen, in *Archiv für Anthropologie*, vol. iv. p. 247).

V. *Religion.*—One of the strongest reasons for considering anthropophagy as having widely prevailed in prehistoric ages is the fact of its being deeply ingrained in savage and barbaric religions, whose gods are so often looked upon as delighting in human flesh and blood. The flesh of sacrificed human victims may even serve to provide cannibal feasts. The understood meaning of these rites may be either that the bodies of the victims are vicariously consumed by the worshippers, or that the gods themselves feed on the spirits of the slain men, their bodies being left to the priests and people. Thus in Fiji, "of the great offerings of food, native belief apportions merely the *soul* thereof to the gods, who are described as being enormous eaters; the substance is consumed by the worshippers. Cannibalism is a part of the Fijian religion, and the gods are described as delighting in human flesh" (T. Williams, *Fiji and the Fijians*, vol. i. p. 231). In Mexico, the anthropophagy which prevailed was distinctly religious in its origin and professed purpose. That the primary meaning of the human sacrifice was to present victims to their deities is shown by the manner in which the sacrificing priest, who tore out the heart, offered it to the sun, and afterwards went through ceremonies of feeding the idol with the heart and blood. It was the Aztec worship of the war-god Huitzilopochtli which brought on the enormous prevalence of sacrifices of prisoners; to obtain supplies of such captives became a motive for frequent wars; and it was the limbs of these victims which were eaten in the sacrificial feasts that formed part of the festivals. (For particulars and authorities see Prescott, *Conquest of Mexico*; Bancroft, vol. ii.; Waitz, vol. iv.) In Africa, also, cannibalism has in some cases evidently a sacrificial character (see Lander, *Records*, vol. ii. p. 250; T. J. Hutchinson, *Ten Years among Ethiopians*, p. 62, &c.)

VI. *Habit.*—The extent to which anthropophagy has been carried among some nations is, no doubt, mainly due to the indulgence of the appetite once aroused. In such cases this reason is openly avowed, or some earlier motive remains rather in pretext than in reality, or the practice is justified on the ground of ancestral custom. It seems, for instance, that the cannibal feasts of old Mexico had become in themselves acceptable to the people, and that we must refer the sickening horrors of Fijian anthropophagy more to sensual gratification than to any religious motive. Among conspicuous cannibal races may be mentioned the semi-civilized Battas of Sumatra, whose original instigation to eating their enemies may have been warlike ferocity, but who are described as treating human flesh as a delicacy, and devouring not only war-captives but criminals, slaves, and, according to one story, their aged kinsfolk (Junghuhn, *Batta-länder*; Marsden, *Hist. of Sumatra*, p. 390; see also Wuttke, *Geschichte des Heidenthums*, vol. i. p. 172; Friedmann in *Zeitschrift für Ethnologie*, 1871, p. 313). Cannibalism assumes its most repulsive form where human flesh is made an ordinary article of food like other meat. This state of things is not only mentioned in past times in descriptions of West Africa, where human flesh was even sold in the market (see Pigafetta, *Regnum Congo*, in De Bry; Wuttke, vol. i. p. 171), but still continues among the Monbuttu of Central Africa, whose wars with neighbouring tribes are carried on for the purpose of obtaining human flesh, the bodies of the slain being dried for

transport, while the living prisoners are driven off like cattle (Schweinfurth, *Heart of Africa*, and in *Zeitschrift für Ethnologie*, vol. v. p. 9). Where cannibalism for its own sake becomes popular among a warlike people, its effect in thinning population, and even in exterminating weak tribes, becomes perceptible. This subject has been investigated by Gerland (*Aussterben der Naturvölker*, p. 61).

As to the history of anthropophagy, the most interesting question is whether at any early period it was ever a general habit of the human race. This has been debated on the evidence of prehistoric human remains (see Schaaf-hausen, *ubi supra*, p. 264; *Proceedings* of Congresses of Pre-historic Archæology, Paris and Copenhagen. It has been well argued that had the men of the quaternary period been cannibals, we should find the bones generally cracked for the marrow like those of beasts, which is not the case (Le Hon, *L'Homme Fossile*, p. 68); also that, as regards the ancient people of the shell-mounds, had they eaten their own species they would have thrown the human bones into the rubbish heaps with those of beasts and fishes (Lubbock, *Prehistoric Times*, p. 232). The discovery of some few ancient human remains, the state of which seems to indicate that the flesh had been eaten, may perhaps be taken to show that prehistoric savages were in this respect like those of modern times, neither free from cannibalism nor universally practising it. During later ages, it may have even increased rather than diminished with the growth of population,—its greatest excesses being found among high savage tribes or nations above the savage level. But with the rise of civilization to its middle and upper levels, it is more and more kept down by the growing sense of the dignity of man, and eventually disappears, as we may hope, irrevocably. (E. B. T.)

CANNING, George (1770–1827), one of the greatest of English statesmen and orators, was born in London on the 11th April 1770. He was descended from an ancient family; but his father, having incurred the displeasure of his parents, was cut off with a scanty allowance, and obliged to try his fortune in the metropolis. Here he studied for the bar, but literature proved too attractive for him, without yielding him even a tolerable livelihood. His affairs were not improved by a marriage with an Irish lady, of good connections and some beauty, but as poor as him-self. He died of a broken heart, a year after the birth of his son. The widowed mother took to the stage without achieving any great success, and in this new way of life married twice,—neither time wisely.

It was thus, in the society of the stage, that the future premier of England passed his earliest years. It was well for him, therefore, when one of his paternal uncles, a wealthy banker in London, took upon himself the care of his education. Young Canning was then in his eighth year, and from that time had all the advantages of the best education and the most cultured society, for Burke, Fox, Sheridan, and other leading Whigs were guests at his uncle's house. After spending a few years at a London school he went in due time to Eton and Oxford. At both places he highly distinguished himself. He was a brilliant scholar, gave promise of the future orator in the debating societies, became known as a wit in a wide circle of admiring friends, and even at Eton, at the age of sixteen, gave decided evidence of literary talent, in a periodical got up amongst his schoolmates. From Oxford he returned to London with the reputation of a man able to perform great things. And now he had to choose between two careers, not easily to be combined by one who had his own way to make in the world. The generous enthusiasm of youth tempted him into a political career; worldly prudence pointed him to the bar as the safer profession for a man without means. Circumstances decided in favour of the former. Pitt was now being drawn into the terrible crusade against the French Revolution, and greatly needed able associates to make head against the fiery eloquence of Fox and Sheridan. To Canning, who soon became known in the clubs and other political circles of the metropolis as a young man of the most brilliant promise, he made the offer of the nomination borough of Newport. This was accepted, and Canning entered Parliament as an adherent of Pitt in 1793, being twenty-three years of age.

Canning is charged with having taken this step from interested motives. In the debating societies of Oxford and the metropolis he had been an enthusiastic Liberal, and had long been the friend of the Liberal leaders. Now, when the prospects of the Whig party were becoming gloomier every day, this crossing over to the ranks of Pitt had a suspicious appearance of convenience. But there is no real ground for such suspicion. With regard to the French Revolution, which was now the all-absorbing political question, Canning simply underwent the same change of opinion as the immense majority of educated Englishmen, Pitt included, hailing it at first as the dawn of a new day for France and Europe, but turning away from it in dismay and indignation, and determined to oppose it, when he saw it was more likely to subvert than to reform society.

From his entrance into Parliament till the death of Pitt in 1806, Canning was an ardent and devoted supporter of all the measures of that statesman. In the House of Commons he soon took his place as one of the most brilliant and successful debaters of the time, though unhappily his efforts needed to be directed against his own friends, Fox and Sheridan; and he gave proof of his business capacity in some of the less prominent departments of the administration. Out of Parliament he fought the Revolution almost as effectively by starting (in 1797) the *Anti-Jacobin*, a weekly paper, in which the principles of innovation in morals, in literature, and above all, in politics, were mercilessly attacked, and their advocates covered with ridicule and abuse. Canning contributed many of the humorous articles, and in this way extended the reputation for caustic wit he had already acquired in Parliament.

In 1800 Canning married Miss Joan Scott. The marriage was in every way a happy and a fortunate one, based on mutual love and esteem, which continued unbroken to the end; while Miss Scott had a large fortune, and was connected with some of the highest of the aristocracy.

On the death of Pitt in 1806, and the formation of a Whig ministry by Fox and the Grenvilles, Canning went into opposition, and showed that, even on a question of humanitarian interest, he was not above the pettiest feelings of party. He supported, but very coldly, the bill for the abolition of the slave-trade.

against the armies of the French conqueror. He encouraged the spirit of resistance in the Spanish nation, supported the Spanish armies, first with supplies of arms, and then with the active co-operation of the English forces, and was one of the first to recognize and employ the military capacity of the future duke of Wellington. Unfortunately, an event soon occurred which deprived the country of his services, when the need was greatest, and when he was the only statesman in England whose talents were of the first order. In 1809, Lord Castlereagh, as Secretary-at-War, had organized the expedition to Walcheren, the worst conducted and the most disastrous of the whole war. In consequence of it a dispute arose between his lordship and Canning, which resulted in a duel, and in the resignation of both. From this unfortunate incident till 1822, Canning took no very prominent part in the Government of the country. This is particularly to be regretted, as the period in question includes the decisive years of the Napoleonic struggle, and the new settlement of Europe by the peace of Vienna, when Canning might have done good service by insisting, more than was done, on the claims of nationality and constitutional liberty. In this he was not free from blame, as he allowed his personal dislikes too much to interfere with his duty to his country. But the chief reason was his advocacy of Catholic Emancipation, which lost him favour at court Men's motives must always remain to some extent doubtful; still it seems clear that at one time his dislike of Castlereagh, at another his insistance on Catholic Emancipation, prevented him from resuming his place in the Foreign Office. He lived to regret this deeply, and to declare that two years of office at the termination of the European struggle would have been worth ten years of life. Even now, however, he was not idle. In 1812 he made a powerful speech in favour of Emancipation, which was carried in the Commons by a large majority, but rejected by the Lords. From 1814 to 1816 he was ambassador at Lisbon, and from 1817 to 1820 President of the Board of Control for India As a member of the Cabinet during the latter period he was very active in support of Government, strongly advocating the coercive measures employed at home during the years which immediately followed the Revolution. It is indeed a noteworthy fact in his political career that, though unable to act with Castlereagh in the most dangerous crisis of the French war, he found it right to join him and his associates in such severe measures of repression,—noteworthy, but quite explicable, as Canning never professed to be anything else than a disciple of Pitt.

At the head of the Board of Control, Canning gained the entire confidence of the directors of the East India Company. In consequence, they had appointed him to the governor-generalship of India, and he had proceeded to Liverpool to take leave of the constituents who had four times returned him to Parliament, when news came of the death of Castlereagh (then earl of Londonderry). The voice of the country had already named him successor in the Foreign Office, and, in this capacity, under the premiership of Lord Liverpool, Canning entered upon the last and most brilliant period of his career. The state of Europe had greatly changed since his resignation of the same office in 1809. The Holy Alliance now aspired to regulate the affairs of the world. Inaugurated by the emperor of Russia, under the inspiration of Madame Krudener, it was at first a sincere attempt of the rulers of Europe to govern on Christian principles. But even the Russian emperor was soon frightened from the path of benevolent reform by the revival of the revolutionary spirit and its appearance in his own army; while interested statesmen like Metternich so utilized the pious aspirations of kings to the profit of despotism, that the Holy Alliance soon became a byword in Europe. Castlereagh had yielded too far to this tendency. The country was getting weary of it. And now Canning came forward to assert the free action of England and the universal right of self-government. He was, however, no revolutionist. In his home and foreign policy alike he aimed at holding a middle course. At home he advocated Catholic Emancipation, and believed in Free Trade, but strenuously opposed Parliamentary Reform. In his foreign policy his principle was that England should hold the balance between the reactionary and the revolutionary parties, "that in order to prevent things going to extremities, she should keep a distinct middle ground, staying the plague both ways." Seeing that the reactionary party predominated in 1822, he judged that England should throw the weight of her influence into the Liberal scales. In accordance with these views, he protested against the doctrine that free institutions should be held only as a spontaneous gift of the sovereign, and disapproved of the measures adopted at the Congress of Verona in 1822, especially of the French invasion of Spain for the restoration of absolutism in 1823,—a year, too, which was marked at home by the passing of the Reciprocity Act, the first step in the direction of Free Trade. In order to render the protest against the invasion of Spain more effectual, it was determined in 1824 to recognize the independence of the South American colonies. On the threatened invasion of Portugal by reactionary Spain in 1826, Canning again interposed with the utmost decision, and the invasion was abandoned. The speeches he made on these occasions, and his general attitude of defiance to despotism, had a marvellous effect, not only in Parliament and in England, but in all civilized communities. He was everywhere hailed as the champion and spokesman of national and popular liberty. The party of progress recovered from the torpor consequent upon the Revolution, and returned to new life. The enthusiasm for his name was heightened when it became known that he had taken the initiative in another act of international justice, by proposing (1826) to France and Russia that combination of the three Powers which led to the battle of Navarino and the establishment of Greek independence.

But ere that result had been attained the great statesman was no more. Early in 1827 Lord Liverpool, who had been the nominal head of the Government since 1812, was disabled Canning, who now became premier, expected the co-operation of the members of the late administration, but was disappointed, and had to struggle on under the greatest difficulties, and against the most virulent opposition. His exciting labours and the alienation of so many friends were too severe for his sensitive temperament. He caught a severe cold, and died on the 8th of August 1827. He was buried in Westminster Abbey, in the Statesmen's Corner, by the grave of his master Pitt.

His death created a sensation commensurate with his world-wide fame and with the hopes still entertained of him. The splendour of his talents was only matched by their versatility. In his high and brilliant career he had proved himself equal to anything—from guiding the destinies of a great nation through the storms of the Napoleonic wars, down to the editing of a comic journal. He had all the natural endowments of a great orator,—a graceful and commanding form, a musical voice, a perfect mastery of the choicest language, and a ready wit that played with all the resources of his intellect. In private life he was even more admirable,—in his own family an almost perfect model of all the household charities, and towards his mother, whose imprudent marriages had endangered his infancy, full of the tenderest and most affectionate piety. (T. K.)

CANNING, CHARLES JOHN, EARL AND VISCOUNT (1812-1862), Governor-General of India, was the youngest child

of the subject of the preceding notice, and was born at Brompton, near London, on the 14th December 1812. He was educated at Christ Church, Oxford, where he graduated B.A. in 1833, as first class in classics and second class in mathematics. In 1836 he entered Parliament, being returned as member for the town of Warwick in the Conservative interest. He did not, however, sit long in the House of Commons; for, on the death of his mother in 1837, he succeeded to the peerage which had been conferred on her with remainder to her only surviving son, and as Viscount Canning took his seat in the House of Lords. His first official appointment was that of Under-Secretary of State for Foreign Affairs, in the administration formed by Sir Robert Peel in 1841,—his chief being the earl of Aberdeen. This post he held till January 1846; and from January to July of that year, when the Peel administration was broken up, Lord Canning filled the post of Commissioner of Woods and Forests. He declined to accept office under the earl of Derby; but on the formation of the Coalition Ministry under the earl of Aberdeen in January 1853, he received the appointment of Postmaster-General. In this office he showed not only a large capacity for hard work, but also general administrative ability, and much zeal for the improvement of the service. He retained his post under Lord Palmerston's ministry until July 1855, when, in consequence of the death of Lord Dalhousie, and a vacancy in the governor-generalship of India, he was selected by Lord Palmerston to succeed to that great position. This appointment appears to have been made rather on the ground of his father's great services than from any proof as yet given of special personal fitness on the part of Lord Canning. The new governor sailed from England in December 1855, and entered upon the duties of his office in India at the close of February 1856. His strong common sense and sound practical judgment led him to adopt a policy of conciliation towards the native princes, and to promote measures tending to the betterment of the condition of the people.

In the year following his accession to office the deep-seated discontent of the people broke out in the mutiny which grew into the Sepoy War. Fears were entertained, and even the friends of the viceroy to some extent shared them, that he was not equal to the crisis. But the fears proved groundless. He had a clear eye for the gravity of the situation, a calm judgment, and a prompt, swift hand to do what was really necessary. By the union of great moral qualities with high, though not the highest, intellectual faculties, he carried the Indian empire safely through the stress of the storm, and, what was perhaps a harder task still, he dealt wisely with the enormous difficulties arising at the close of such a war, established a more liberal policy and a sounder financial system, and left the people more contented than they were before. While rebellion was raging in Oude, he issued a proclamation declaring the lands of the province forfeited; and this step gave rise to much angry controversy. A "secret despatch," couched in arrogant and offensive terms, was addressed to the viceroy by Lord Ellenborough, then a member of the Derby administration, which would have justified the viceroy in immediately resigning. But from a strong sense of duty he continued at his post: and ere long the general condemnation of the despatch was so strong that the writer felt it necessary to retire from office. Lord Canning replied to the despatch, calmly and in a statesman-like manner explaining and vindicating his censured policy. In April 1859 he received the thanks of both Houses of Parliament for his great services during the mutiny. He was also made an Extra Civil Grand Cross of the Order of the Bath; and in May of the same year he was raised to the dignity of an earl. By the strain of anxiety and hard work his health and strength were seriously impaired; and in the hope that rest in his native land might restore him, he left India, reaching England in April 1862. But it was too late. He died in London on the 17th of June following. About a month before his death he was created K.G. As he died without issue the title became extinct.

CANNON. See GUNS AND GUNNERY and ARTILLERY.

CANO, ALONZO (1600–1667), one of the most vigorous of the Spanish painters, and also, like Michelangelo, with whom he is usually compared, an architect and sculptor of great merit. He has left in Spain a very great number of specimens of his genius, which display the boldness of his design, the facility of his pencil, the purity of his flesh-tints, and his knowledge of chiaroscuro. He was a native of Granada, and a contemporary of Velasquez and Pacheco, whom he rivalled without imitating. As a statuary, his most famous works are the Madonna and Child in the church of Nebrissa, and the colossal figures of San Pedro and San Pablo. As an architect, he indulged in too profuse ornamentation, and gave way too much to the fancies of his day. Philip IV. made him royal architect and king's painter, and gave him the church preferment of a canon. He was notorious for his ungovernable temper; and it is said that once he risked his life by committing the then capital offence of dashing to pieces the statue of a saint, when in a rage with the purchaser who grudged the price he demanded. His known passionateness also (according to another story) caused him to be suspected, and even tortured, for the murder of his wife, though all other circumstances pointed to his servant as the culprit.

CANO, or CANUS, MELCHIOR (1523–1560), a learned Spanish bishop and theologian, who was pupil and successor of Vittoria as professor of theology at Salamanca. He had one, and only one, rival as to erudition in Spain, Bartolomeo de Carranza, like himself a Dominican, and the university was divided between the partizans of the two professors. On account of his violent opposition to the establishment of the Jesuits in his native country, he was summoned by Pope Paul III. to the Council of Trent, and appointed to the distant see of the Canaries. But his influence with Philip II. procured his recall to Castile, where he became provincial of the Dominican order. His principal works are entitled *Prælectiones de Pœnitentia*, *De Sacramentis*, and *Locorum Theologicorum Libri XII.*

CANOE, a species of boat. In several Eastern languages the word *kan* means something hollow, with a certain degree of strength. Pliny says some Indian reeds are long enough to form a boat for three men between the joints. The French *canot*, Spanish *canoa*, Italian *canoe*, are derived from the Latin *canna*; but a canoe is sometimes called in France *bateau*, *bac*, *pirogue*, *caïque*, *chaloupe*, *navire*, *nacelle*, or *périssoir*, and the paddle *pagaye*, and the canoeist *pagayeur*. The English word "canoe" may be defined as a boat propelled by one or more paddles used without a fixed fulcrum on the boat, and therefore invariably with the sitter facing towards the bow. The Venetian gondola and the Maltese boats, and many others, are rowed by men who face the bows, but they always have a fixed rest for the rowlock. Canoes are made of various substances. Those of the Esquimaux are of seal-skin stretched over whalebone, and are propelled by the double-bladed paddle, 7 feet long and 6 inches broad, used by one man, whose dress is united with the deck covering, so as to be watertight.

The North American "dug-out" canoe is made from a tree hollowed by fire, while the bark canoes are formed by birch bark sewn together, according to the size required, until the craft will hold as many as seventy men. Paper canoes have been used in the United States. Cork leather

would probably be a very good material. Canoes of tin and of india-rubber have been used in England, but practically all the best canoes now built in England, America, and France for general travelling are of oak, cedar, or pitch pine. The canoe was popular in England more than twenty years ago at Oxford and Cambridge, but only for short river practice, until in 1865 one was specially designed for a long journey by water in seas, lakes, and rivers, and by carriage on land in railways or carts or on horseback, or by being dragged over rough ground or borne on men's shoulders through woods and over hills.

The general type of this "Rob Roy" canoe is built of oak with a cedar deck. The length is from 12 to 15 feet, and the beam from 26 to 30 inches, the depth 10 to 16 inches. The paddle is 7 feet long with 6 inches of breadth in the blade, and is either double-bladed, or, if it is used with a single blade, a rudder is worked by the foot to counteract the lateral swerving. A backboard swinging with the paddler's motion enables the canoeist to sit in a comfortable position for many hours at a time, and a mast with some light sails completes his equipment, so that a favourable wind eases the muscular exertion. An ordinary travelling canoe when complete weighs about 70 lb. It will float with its paddle and 10 lb of luggage in 5 inches of water. In the Indian canoes of America the single paddle is usually employed, and the men kneel to the work. The canoeists in the Straits of Magellan paddle standing. The peculiar advantages of a canoe may be summed up thus:—

1. The canoeist faces forwards in the direction of his progress, and therefore he can readily steer without turning his head round.

2. His centre of gravity is five or six inches below what would be necessary in a row-boat, and therefore the canoe is more steady, and is very suitable for shooting from. When the action of the paddle stops the canoeist is at once in comfortable rest. In descending a rapid where rocks or snags are numerous, the canoeist has much power of seeing and avoiding danger, while he can also get out readily, and can sit on the deck in places where the feet, being in the water, are of service in warding off collisions.

3. The knees of the canoeist press outwards against the sides of the "well" or opening in the deck, so that in high seas there is ample "purchase" for counteracting an upset, while the canoeist can use great power with his paddle at a critical moment for lifting the craft over a wave. The alternate action of the arms opens the chest, and the legs are continually exercised by pressure against the stretcher, while the sway of the whole body at each stroke of rowing is dispensed with.

4. He can instantly hoist sail without leaving his place or shifting ballast, and he can fish or shoot conveniently without changing his seat. He can sleep in the canoe when it is properly prepared.

5. The canoe being impelled without rowlocks, by pressure through the legs to the feet resting on the stretcher, and by only one implement (the paddle), the joints of the planks and the nails and fastenings, are not loosened, as in other boats, by the jerky leverage of rowlocks.

6. The deck covering (not feasible in a row-boat) protects the paddler and his luggage from wind, rain, and sea, and adds to the "stiffness" of his craft, so that it can be dragged on rough ground without injury. A canoe should have a very flat floor and small keel; this secures stability, while it diminishes speed to a very small extent.

7. Ladies and young children can conveniently use the canoe because of its safety and the simplicity of its mode of propulsion. Many double canoes are used in England, and some with four paddlers together.

For actual speed over a short and straight course the ordinary sculling skiff is superior to the canoe, but for long journeys of more than a week's duration, and in strange rivers, or with frequent portage, rough usage, intricate navigation, or unexpected difficulties, the canoe is found to be much more convenient than the rowing boat. Forty miles a day in lakes can be kept up for weeks together in a travelling canoe, unless against a contrary wind. Fast racing canoes are 20 feet long and 18 inches broad, and attain a speed of 8 miles an hour. Canoes for "upset races" (where the canoeist has to jump out, tow his boat while swimming, and then get in) and for the race "over land and water" are specially built for their purpose. Other canoes are built chiefly for sailing, and these carry "drop keels," "rockers," and heavy ballast.

In 1866 the Royal Canoe Club was formed in England, and the Prince of Wales became commodore, while about 500 members have been elected in various parts of the world. After the English canoes were seen in Paris at the Exhibition of 1867, others like them were built in France. Branches and clubs were formed also at the English universities, and in Liverpool, Hull, Edinburgh, Glasgow, and New York. A publication called *The Canoeist* records the more important cruises in canoes in almost every country on the globe. One member of the club crossed the English Channel from Dover to Boulogne in his canoe, another from Boulogne to Dover, and a third crossed the Irish Channel from Scotland to Ireland. Many old and new rivers have been explored for the first time in canoes, among which the most interesting were the hitherto inaccessible parts of the Jordan, the Kishon, and the Abana and the Pharpar at Damascus, as well as the Lake Menzaleh in the Delta of the Nile, and the Lake of Galilee and Waters of Merom in Syria. So far as has been ascertained, not one of the members of the Royal Canoe Club has been drowned in any of the numerous long cruises performed.

See Macgregor's *A Thousand Miles in the Rob Roy Canoe*, *The Rob Roy on the Baltic*, and *The Rob Roy on the Jordan, Red Sea, Nile, and Gennesareth, &c.*; *Canoe Travelling*, by W. Baden Powell; *Cruise in a Cockle Shell*, by A. H. Reed; *The Canoeist* (Royal Canoe Club). (J. M'G.)
